PREFACE

Carcinogenesis Abstracts is a publication of the National Cancer Institute. The journal serves as a vehicle through which current documentation of carcinogenesis research highlights are compiled, condensed, and disseminated on a regular basis. It represents an integral part of the Institute's program of fostering and supporting coordinated research into cancer etiology. Issues of *Carcinogenesis Abstracts* normally contain three-hundred-fifty abstracts and three-hundred-fifty citations (unaccompanied by corresponding abstracts). Abstracts and citations refer to the current scientific literature that describes the most significant carcinogenesis research carried on at the National Cancer Institute, other governmental agencies, and private institutions. *Carcinogenesis Abstracts* is intended to be a highly useful current awareness tool for scientists engaged in carcinogenesis research or related areas. The great number and diversity of publications relevant to carcinogenesis make imperative the availability of this service to investigators whose work requires that they keep abreast with current developments in the field.

Carcinogenesis Abstracts is normally published monthly. Volume X covers the scientific literature published from July 1971 through Dec 1972. A cumulative subject and author index for Volume X will be published shortly after the final regular issue. This journal is available free of charge to libraries and to individuals who have a professional interest in carcinogenesis. Requests for *Carcinogenesis Abstracts* from qualified individuals should include statements of their relationship to carcinogenesis research. All correspondence should be addressed as follows.

Carcinogenesis Abstracts
Etiology Area
National Cancer Institute
National Institutes of Health
Bethesda, Maryland 20014

Use of Funds for Printing this publication
approved by the Director of the Bureau of
the Budget on July 25, 1967.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

001 LESS HARMFUL WAYS OF SMOKING. (E.) Wynder, E. L. (Amer. Hlth. Fdn., New York, N.Y.) and D. Hoffmann. - *J Nat Cancer Inst* 48(6):1749-1758, 1972.

Data on the relationship of cancer and smoking are reviewed, and evidence that different smoking habits are associated with different cancer risks is presented. Although cigar and pipe smokers are at less risk of developing lung cancer than cigarette smokers, excessive pipe and cigar smoking enhances cancer risk. Furthermore, cigar and pipe smokers have a high risk for cancer of the upper alimentary tract. Harmful agents in tobacco smoke are of three types: tumor initiators (including polycyclic aromatic hydrocarbons), tumor accelerators (including 9-methylcarbazole and 1-methylindole) and tumor promoters (including phenol). Smoke from high-nitrate tobacco, from terpene-free tobacco stems, and from cigarettes made of reconstituted tobacco sheets appears to be less carcinogenic than smoke from conventional cigarettes. Reducing the amount of smoke coming in contact with lung tissue also appears to reduce cancer risk. In one study it has been shown that filter cigarette smokers of at least ten years duration have lower risks of developing lung cancer than non-filter smokers. The diminished risk for lung cancer among pipe and cigar smokers compared to cigarette smokers is probably related to diminished depth of inhalation of tobacco smoke among pipe and cigar smokers. The importance of monitoring human smoking habits in the evaluation of smoking hazards is stressed. (27 references)

2902 THE NECROPSY FINDINGS IN CARCINOMA OF THE BRONCHUS. (E.) Line, D. H. (Hammersmith Hosp., London, England) and T. J. Deeley. *Brit J Dis Chest* 65:238-242, 1971.

The findings in 680 necropsies in which a carcinoma of the bronchus was found are reviewed. Data were obtained from a highly selected group of patients who had bronchial carcinoma, died in a hospital, and had a routine necropsy examination. Histological diagnosis showed that 38% of the cases were squamous cell carcinoma, 28% were oat cell, 26% were anaplastic, and 8% were adenocarcinoma. The most common site of primary involvement was the upper lobes. The right middle lobe was rarely involved. The right side showed slightly more involvement (54%) than the left (46%). Four percent of the cases has primary carcinomas at sites other than the lung. Metastatic spread in this series was slightly more common by hematogenous than by lymphatic routes for each of the four histological types. For each histological type, the incidence of soft tissue metastases was greater than that of bone metastases. Metastases were more common with oat cell tumors and less frequent with squamous cell tumors. Squamous cell tumors also had the highest incidence of "solitary metastases". The incidence of metastases in adenocarcinomatous lesions was relatively high. In nine percent of the cases (primary squamous cell) there were no metastases. Metastases occurred most frequently in the lymph nodes (hilar nodes in

83%), liver (40% of all cases), adrenals, bones (most common in vertebrae, 25%) and brain (most common site was the cerebellum, 76%). Bone and brain metastases were most common with oat cell and adenocarcinomas. (8 references)

2903 IMMUNOLOGICAL PROBLEMS IN ONCOLOGY. (It.) Gazzera, G. (European Org. Res. Treatment Cancer, Torino, Italy). *G Batt Virol Immun* 64(1-4): 37-80, 1971.

No matter whether tumors are spontaneous or produced by chemical carcinogens or viruses, specific tumor antigens are produced which vary from one tumor to another. These antigens cause a delayed antibody response in the host and can overcome his immune defense, in which case the tumor develops. When experimental tumors are transplanted and then removed surgically, the inoculated animal and the original host both become immune to the tumor. The main obstacles to heteroimmunization are that the specific antigen is probably present in a very small fraction of impure preparations of malignant tissues, that it cannot produce immunization, and that the chemical composition and cell site of these specific antigens are not known in many cases. When newborn animals are inoculated with oncogenic viruses, they develop tumors because they are not yet able to produce antibodies against the tumors. Some normal adults, however, have antibodies, suggesting that they were probably infected under normal conditions. Neoplastic cell transformations are associated with changes in cellular antigenic determinants resulting in the loss or reduction of isoantigens or the acquisition of new antigens. There are five mechanisms by which the tumor cell can escape from immunological control: (1) insufficient liberation of antigen, (2) the development of tumors in a favored site, (3) potentiation of antibodies, (4) immune-specific depression, and (5) immune tolerance. The use of immunotherapy in the treatment of tumors in man is discussed. (137 references)

2904 THEORY ON ATOMIC ENERGY LEVEL CHANGES AS A CAUSE OF CANCER: THE ROLE OF ^{40}K IN CARCINOGENESIS. (Sp.) Guiglia, S. F. (French Hosp. Los Angeles, California). *Folia Clin Int* 21(10):611-612, 1971.

Loss of aluminum by red blood cells (RBC) makes it possible for ^{40}K to pass into the serum and be absorbed by radiosensitive tissue. The protective action of Al may be due to its capacity to decrease the kinetic energy of ionized particles which come into contact with it. ^{40}K in the RBC may have a carcinogenic effect resulting from (1) absorption of radiation by the cells due to the proximity of the RBC, (2) phagocytosis of RBC by the cells, or (3) preferential absorption of ^{40}K from the pool of RBC. The gamma rays emitted by ^{40}K can interact with tissue and produce Compton electrons. (No references)

2905 THE VIRAL ETIOLOGY OF CERTAIN OSTEOGENIC
OSTEOSARCOMAS: A CRITICAL REVIEW. (Rev.)

Latarjet, R. (Curie Fdn., Paris, France). *Bull Cancer (Paris)* 58(2):277-286, 1971.

Studies published since 1966 on the viral origin of certain osteogenic osteosarcomas are reviewed. Cell-free extracts of human osteogenic osteosarcomas induced tumors of the same type when injected into newborn hamsters. The serum of patients contained a specific neoantigen of these tumors. If these findings are confirmed beyond a doubt then this is the first carcinogenic virus detected in man. That certain tumors produced by 90Sr in mice contain FBJ (Finkel) virus has been confirmed ultramicroscopically and by the induction of osteosarcomas by these extracts. The sarcomas induced by osteophilic radioactive elements are probably due to a preexisting virus in the bones of mice whose activity is inhibited under normal conditions. Spontaneous bone tumors in rodents occur rarely. A cell-free extract from a spontaneous vertebral osteosarcoma in a male CFI mouse, injected into newborn CFI mice, produced vertebral osteosarcoma in 280 days and a second one 60 days later. With subsequent passages the induction time was reduced to 84 days; 21% of the mice developed bone tumors in various sites. Electron microscopy showed oncornavirus type virions in the extract resembling those producing leukemia or sarcomas in birds and rodents. In a subsequent series of 106 mice, 35% contracted osteosarcomas. Bone tumors produced by the murine leukemia-sarcoma virus, characteristics of the FBJ virus, and findings on the viral etiology of human osteosarcomas are described. Therapy of tumors induced by a virus theoretically should be an antiviral therapy, possibly the administration of a non-carcinogenic virus resembling the causative virus which progressively displaces it. Partial success was achieved by this procedure on humans. (21 references)

2906 RECENT RESEARCH IN BURKITT'S LYMPHOMA.

(E.) Ziegler, J. L. (Uganda Cancer Inst., Kampala) and S. K. Kyalwazi. *E Afr Med J* 48(11):670-675, 1971.

The clinical features of Burkitt's lymphoma have permitted its separation into four stages: I, single facial tumor; II, two or more facial tumors; III, intrathoracic, intra-abdominal or osseous tumor; IV, tumor cells in the cerebrospinal fluid and/or bone marrow. The current treatment of choice is repeated i.v. administration of cyclophosphamide (Endoxan) at two to three wk intervals until complete remission. About 80% of all treated patients attain complete remission after one or two doses, while 15% die, usually due to extensive disease or complications. About 5% show a partial response to therapy. Class IV patients should receive methotrexate. Radiation therapy should be restricted to patients with localized disease. Surgical excision of large tumors should be attempted, if feasible, before further therapy. Two types of relapse occur—early and late. Early relapses, which

are seen in one-third of those achieving full remission and occur within ten wk of initial therapy, usually involve the same anatomic site and frequently involve the central nervous system (CNS). Early relapses generally occur in patients of class III or IV; their response to subsequent therapy is usually partial or transient with a median survival of 34 wk. Late relapses involve tumors at other than the primary site (excluding the CNS) and can be as successfully treated as the original tumor. It has been suggested that early recurrence is due to regrowth of the primary tumor, whereas late recurrence is due to reinduction of tumor. The high percentage of long term remissions has implied that the host's immunological responses may assist in eliminating residual tumor following therapy. Although a search for tumor-specific humoral antibodies has been unrewarding, antibodies directed against Epstein-Barr (EB) virus have been found. In addition, a tumor-specific delayed hypersensitivity reaction has been found in some patients during clinical remission, but not during relapse. Although EB virus is the prime etiological candidate, the geographic association of Burkitt's lymphoma with malaria suggests another possible etiology of the disease. (18 references)

2907 DEPRESSION OF THE LOCAL RESPONSE IN PRE-CANCEROUS CONDITIONS: A SCHEME OF ONCO-GENESIS. (Sp.)

Sadoff, L. (Dept. Med. "Kaiser Fdn. Hosp.", Los Angeles, Calif.). *Folia Clin Int* 21(10):615-620, 1971.

It is known that children, patients treated with immunosuppressive agents, patients with immune deficiencies, and elderly subjects are prone to cancer. Many infectious diseases have also been associated with a predisposition to cancer which is attributed to a saturation of the immune system. Thus, malaria is associated with Burkitt's lymphoma, syphilitic glossitis with tongue cancer, and pulmonary tuberculosis with lung cancer. Some autoimmune diseases are also associated with a predisposition to cancer. Thus, pulmonary scleroderma is associated with bronchopulmonary carcinoma, pernicious anemia with gastric adenocarcinoma, and ulcerative colitis with adenocarcinoma of the colon. Some physical and chemical carcinogens act as foreign bodies and induce a macrophage response in the host, e.g. tobacco smoke produced functional impairment of alveolar macrophages. In order to unify the viral and immunological theories about the origin of cancer, it is suggested that oncogenic viruses produce a change in the immune system which results in cancer. To test the hypothesis that the local cellular immune response is depressed in precancerous states, tuberculin skin tests were made directly over scars from burns and on smallpox vaccinations in normal subjects; control tests were run at the same site on the opposite arm. In all cases the skin reaction was less pronounced on the scars than on the control site, suggesting that cellular immunity is decreased in injured skin and perhaps in other organs with lesions or changes. These results are being quantified for publication elsewhere. (No references)

2908 MECHANISMS OF ESTABLISHMENT OF TUMOR METASTASES. (E.) Wood, S., Jr. (No affiliation). *Pathobiol Ann* 1:281-308, 1971.

The endogenous factors that might control tumor metastases are discussed. Investigations reported were primarily focused on direct observations through cinemicrographic techniques of the sequences occurring *in vivo*. The sequence of metastatic establishment is presented diagrammatically, including the lodgement, survival, and growth of cells from a primary neoplasm. Extensive time-lapse analyses of cellular behavior served as a means for documenting the locomotion of individual cancer cells, thus providing new and fundamentally informative data. In observing the relationship between thrombosis and cancer, indications were found that anticoagulants or plasmin reduce the frequency of metastases forming from blood-borne cancer cells. It is suggested that progress in cell research will be greatly accelerated with the development of less cumbersome study techniques. (69 references)

2909 VIRUSES AND BREAST CANCER: INTRODUCTORY REMARKS. (E.) Dmochowski, L. (U. Texas M. D. Anderson Hosp. Tumor Inst., Houston). *Cancer* 28(6):1404-1405, 1971.

Mouse mammary cancer is a systemic disease produced by diverse factors such as genes, or genetic factors; hormones; a virus (or viruses); and environmental factors. They all are closely interrelated and in their interplay lead eventually to the clinical appearance of breast cancer in these animals. It is known that a virus of characteristic morphology, the type B particle, transmitted in mothers' milk is the causative factor, if all other factors already mentioned are present. The virus is present in most organs of the animals, including the blood. The virus is present in the organs, including mammary glands and milk, long before clinical symptoms of neoplasia are observed. The virus, or type B particle, is also present in breast cancer cells of mice and can be maintained for prolonged periods of time in tumor cells grown in tissue culture. Attempts to find susceptible cells which can be transformed *in vitro* by the virus have so far failed. The only cells which support the growth of the virus *in vitro* are tumor cells and only cells of a few breast tumors have produced stable cell lines after tedious and extensive trials. Although the presence of the type B particle does not necessarily indicate future development of neoplasia in the host, a correlation does exist between high numbers of type B particles in milk of animals and high incidence of breast cancer in mice. In addition to milk, the type B virus particles are present in testicular tissues and in the spermatic fluid, which is infectious to female mice of a suitable susceptible genetic constitution. The virus has not been found in the egg or sperm itself, although the viral genome can apparently be transmitted in the sex cells of mice of at least one strain. Breast cancer cells of mice contain viral antigens which can be detected by immunologic techniques. Further, the type B virus particles contain RNA-dependent DNA polymerase.

Thus, these particles belong to the group of viruses known as oncogenic, or so-called oncornaviruses. (No references)

2910 AN EPIGENETIC MECHANISM FOR CARCINOGENESIS. (E.) Tsanev, R. (Bulgarian Acad. Sci., Sofia) and B. Sendov. *Z Krebsforsch* 76(4):299-319, 1971.

This review compares the main characteristics in the process of cytodifferentiation with those of carcinogenesis. Their multiphasic aspects are described and on the basis of available biochemical data a proposed molecular mechanism for blocking and de-blocking in normal cellular activity is presented. A detailed discussion of a computer reproduction of the functional interrelations of the neoplastic process includes consideration of hereditary patterns, mitotic activity, preneoplastic changes, and a mathematical description of the computer process itself. 23 THE INFLUENCE OF CARCINOGENIC DOSAGE AND OF SEX ON THE INDUCTION OF EPITHELIOMAS AND SARCOMAS IN THE DORSAL SKIN OF RATS. (E.) Cherry, C. (Strangeways Res. Lab., Cambridge, England) and Glucksmann. *Brit J Cancer* 25(3):544-564, 1971.

Studies extending over 15 yrs, male and female hooded Lister rats, castrated at age 3-4 wk in some cases, were given 7,12-dimethylbenz(a)anthracene (DMBA) topically (1% solution) beginning at age 8 wk. Rats were given 4, 5, 10, 20 or 40 weekly doses of DMBA, and the induction of skin tumors was observed. Hypertrophy, hyperplasia and adenomas of sebaceous glands were seen in almost all rats given one or more doses of DMBA. The histogenesis of epidermal tumors proceeded via hyperplasia of interfollicular regions to the formation of papillomas. Malignant changes to squamous cell tumors occurred in papillomatous regions. Rats given four DMBA doses failed to produce skin tumors, and five doses increased tumor production. Ten DMBA doses, however, produced a marked increase in tumor development over four and five doses; rats given ten doses showed more tumors per rat and a higher carcinoma-to-papilloma ratio than rats given fewer doses. Squamous carcinoma incidence in male and female intact and castrate rats was similar at all dose levels. Tumor induction increased with number of DMBA doses to 20 doses, and decreased in intact rats given 40 doses. The optimal dose -- 20 doses -- produced more sarcomas in male than female rats. Progression to malignancy was fast for sarcomas, slow for basal cell tumors. Malignant precursor lesions and fibromas occurred in only 1% of rats given DMBA. Forty percent of rats at all dose levels had sarcomas, 64% had basal cell papillomas and 9% had basal cell carcinomas. Sixty-six percent of all rats developed squamous cell carcinomas, while 1% developed squamous cell papillomas.

24 MORPHOLOGICAL AND BIOCHEMICAL STUDY IN X-RAY- AND DIBUTYRYL CYCLIC AMP-INDUCED DIFFERENTIATED NEUROBLASTOMA CELLS. (E.) Prasad, N. (U. Colorado Med. Ctr., Denver) and A. Karnadakis. *Exp Cell Res* 70(1):27-32, 1972.

Mouse neuroblastoma cells (NB) were cultured from the primary tumor and exposed to 800 Rads X-irradiation (total dosage, delivered in a single dose or in four doses) or to dibutyryl adenosine 3':5'-cyclic monophosphate (DBcAMP) (0.5 mM). X-irradiation and DBcAMP induced morphological differentiation of NB cells, as evidenced by axon formation. Appreciable increases in number of differentiated cells were seen by 24 hr after X-irradiation or DBcAMP; the maximum number of differentiated cells was seen three days posttreatment. Differentiated cells showed morphological maturation as evidenced by increases in cellular and nuclear size. NB cells in the presence of DBcAMP continued to grow at a slightly reduced rate for two days; by three days they had reached a plateau phase. The removal of DBcAMP and re-addition of fresh growth medium at day four posttreatment did not cause renewal of cell division. The number of differentiated cells did not change after removal of DBcAMP, either, indicating that the change to morphological differentiation

was irreversible. Na-butyrate, 3':5'-cyclic AMP, 5' AMP, ATP, ADP and 3':5' cyclic guanosine monophosphate inhibited growth of NB cells but did not produce morphological differentiation. Acetylcholinesterase activity per NB cell was ten times higher in X-irradiated or DBcAMP-treated cells. Na-butyrate and 3':5'-cyclic AMP also increased acetylcholinesterase activity in NB cells.

2925 INHERITED SUSCEPTIBILITY OF INBRED STRAINS OF SYRIAN HAMSTERS TO INDUCTION OF SUBCUTANEOUS SARCOMAS AND MAMMARY AND GASTROINTESTINAL CARCINOMAS BY SUBCUTANEOUS AND GASTRIC ADMINISTRATION OF POLYNUCLEAR HYDROCARBONS. (E.) Homburger, F. (Bio-Res. Inst., Cambridge, Mass.), S.-S. Hsueh, C. S. Kerr and A. B. Russfield. *Cancer Res* 32(2):360-366, 1972.

BIO Syrian hamsters of 12 inbred strains, and hamsters in one randomly bred strain, were given s.c. injections of 500 µg of 3-methylcholanthrene (MC), benzo(a)pyrene (BP), 7,12-dimethylbenz(a)anthracene (DMBA), or benz(a)anthracene (BA); other animals were fed 5 mg MC by stomach tube. The development of tumors in the inbred strains was observed. DMBA induced nodules in all strains within three wks; MC, BP and BA did not elicit immediate local reactions. Sarcomas at the injection site ultimately developed in most strains given MC, DMBA or BP. BA, however, produced no tumors at the injection site. Ten percent of females in one strain developed bronchiolar adenocarcinomas associated with BA injection. Marked differences in susceptibility and in rate of tumor formation were evident in the different strains. The same three lines were always more susceptible than others to the carcinogens. MC feeding caused gastric and intestinal tumors in three inbred lines but caused no gastric tumors in the randomly bred line. Susceptibility of MC-fed animals to mammary tumors was higher in inbred animals than in noninbred animals. Ovarian and uterine tumors also appeared in MC-fed hamsters. Tumor incidence following MC feeding varied widely among hamster strains. It was concluded that genetic constitution determines the responsiveness of hamsters to carcinogens.

2926 PARTIAL PURIFICATION AND CHARACTERIZATION OF TWO ENZYMES FROM GUINEA-PIG LIVER MICROSOMES THAT HYDROLYZE CARCINOGENIC AMIDES 2-ACETYLAMINOFLUORENE AND N-HYDROXY-2-ACETYLAMINOFLUORENE. (E.) Järvinen, M. (Dept. Anatomy, U. Turku, Finland), R. S. S. Santti and V. K. Kopsu-Havu. *Biochem Pharm* 20: 2971-2982, 1971.

Two enzymes capable of deacylating carcinogenic compounds N-hydroxy-2-acetylaminofluorene (N-hydroxy-AAF) and 2-acetylaminofluorene (AAF) were liberated with sonication from guinea pig liver microsomes. The enzymes were separated by fractionation with ammonium sulfate and chromatography on Sephadex and hydroxylapatite or DEAE-cellulose. The Enzyme I (mol. wt. 200,000) hydrolyzed N-hydroxy-AAF 265 times faster than AAF, while Enzyme II (mol. wt. 41,000) hydrolyzed AAF about 1.4 times faster than N-hydroxy-AAF. Both enzymes hydrolyzed the acylamido derivatives of fluo-

rene and naphthalene faster than those of benzene. Substitution of the acyl hydrogen atoms enhanced markedly the hydrolysis rates. Both enzymes hydrolyzed readily ester substrates, e.g. tyrosine ethyl ester and 1-naphthyl acetate, and were inhibited by the organic phosphorus compounds.

- 2927 ON THE BIOCHEMICAL MECHANISM OF TUMORIGENESIS IN MOUSE SKIN: IV. METHODS FOR DETERMINATION OF FATE AND DISTRIBUTION OF PHORBOL ESTER TPA. (E.) Kreibich, G. (German Cancer Res. Ctr., Heidelberg), I. Witte and E. Hecker. *Z Krebsforsch* 76(2):113-123, 1971.

Female NMRI mice were treated on their back skin with a single application of the tritium-labelled phorbol ester A_1 (TPA- $20\text{-}^3\text{H}$). The distribution of the radioactivity in the skin ("epidermal fraction" and "connective tissue fraction") and internal organs (liver, kidney, spleen) at different time intervals after administration of the phorbol ester was investigated. In mice which were kept singly and prevented from licking their back skin about 65% of the total radioactivity administered was detectable in the treated area 12 hours after application of TPA- $20\text{-}^3\text{H}$. The rest of the radioactivity was found in the carcass (20%) and in the cage (15%). In mice which were not prevented from licking 12 hours after administration of TPA- $20\text{-}^3\text{H}$ only 15% of the activity administered was found in the treated skin area, 40% in the carcass and 40% in the cage. The radioactivity extractable from the "epidermal fraction" (10%) of such mice consisted of unchanged TPA (8%) and of metabolic products (2%). One of the metabolites may be either phorbol-13-acetate or 12-O-tetradecanoyl-phorbol. Possible pathways of metabolism of phorbol esters as well as the problem of the "ultimate tumor promoter" are discussed.

- 2928 ARYL HYDROCARBON HYDROXYLASE AND POLYCYCLIC HYDROCARBON TUMORIGENESIS: EFFECT OF THE ENZYME INHIBITOR 7,8-BENZOFLOAVONE ON TUMORIGENESIS AND MACROMOLECULE BINDING. (E.) Kinoshita, N. (Natl. Cancer Inst., Bethesda, Md.) and H. V. Gelboin. *Proc Nat Acad Sci USA* 69(4):824-828, 1972.

Male NIH Swiss mice were given single or repeated topical applications of 100 nmol 7,12-dimethylbenz(a)anthracene (DMBA) or benzo(a)pyrene; some mice were given topical 7,8-benzoflavone in the carcinogen solution or in acetone following carcinogen painting. In three experiments, 7,8-benzoflavone given together with a single dose of DMBA inhibited DMBA tumorigenesis by 80, 55 and 74%. 7,8-Benzoflavone had little effect on benzo(a)pyrene tumorigenesis (40% inhibition in one case, none in two other cases). In some cases, 7,8-benzoflavone stimulated benzo(a)pyrene tumorigenesis by about 2-fold. 7,8-Benzoflavone inhibited tumorigenesis by repeated doses of DMBA by 74, 69 and 30% resp., in three experiments, while 7,8-benzoflavone did not inhibit, or enhanced 3-6 fold, tumorigenesis by repeated benzo(a)pyrene doses. It was

found that 7,8-benzoflavone inhibited the binding of DMBA to DNA, RNA and protein in mouse skin. 7,8-benzoflavone inhibited binding of benzo(a)pyrene to DNA and protein to about the same extent as it inhibited DMBA binding to DNA and protein; benzo(a)pyrene binding to DNA, however, was not as markedly reduced by 7,8-benzoflavone as was DMBA binding to DNA.

- 2929 INHIBITION BY ERGOCORNICINE OF INITIATION AND GROWTH OF 7,12-DIMETHYLBENZANTHRAcene-INDUCED MAMMARY TUMORS IN RATS: EFFECT OF TUMOR SIZE. (E.) Clemen, J. A. (R) Lilly Company, Indianapolis, Ind.) and C. J. Sliger. *Cancer Res* 32:659-662, 1972.

Fifty-eight female Sprague-Dawley rats were treated with ergocornine (0.4 mg, s.c. daily) beginning 11 days before a single i.v. injection of 5 mg 7,12-dimethylbenzanthracene (DMBA); ergocornine treatment was continued for five days after DMBA treatment. After mammary tumors induced by DMBA appeared, 33 tumor-bearing rats were selected; some of these were given continued ergocornine treatments and others (controls) were treated with corn oil. Ergocornine significantly inhibited mammary tumor induction by DMBA. Ergocornine also caused significant regression of developed mammary tumors; 62% of mammary tumors on ergocornine-treated rats regressed completely. Two months after termination of ergocornine treatment, 64% of regressed tumors were found not to have recurred. Tumors of about 1.8 cm³ in volume and smaller regressed rapidly with ergocornine, while tumors of about 14.1 cm³ were not inhibited by ergocornine. Growth inhibition and regression to various degrees were seen in tumors between 1.8-14.1 cm³ in volume. Apparently mammary tumors start to lose their hormone dependence as they grow larger, eventually losing hormone dependence completely in some cases.

- 2930 ACUTE EFFECTS OF HEPATOCARCINOGENS ON MOUSE-LIVER MICROSOMAL ANTIGENS. (E.) Ingleton, P. M. (Dept. Zool., U. Sheffield, England). *Europ J Cancer* 7(6):501-504, 1971.

Female Strong A mice were given a single i.p. injection of 10 mg 2':3 dimethyl-4-aminoazobenzene (o-AAT), an hepatocarcinogen. A submicrosomal fraction of the liver was prepared which consisted essentially of endoplasmic reticulum membranes (M fraction); the effect of o-AAT on antigens in the M fraction was examined using Ouchterlony's double diffusion with rabbit antisera to the M fraction (anti-M) and to the M fraction of livers from mice given o-AAT (anti-DM). Forty-eight hrs after o-AAT injection, a slow-diffusing antigenic component had disappeared from the M fraction. When anti-DM was tested against the M fraction of livers from o-AAT-treated mice, a new precipitin line developed. A similar decrease in one M fraction antigen and increase in another was also seen in the M-fractions of livers from mice given o-AAT in diet for two wks. The non-carcinogenic 4:5' dimethyl-2-aminoazobenzene did not affect the antigenic character of the liver M fraction.

2931 INFLUENCE OF BLOOD TRANSFUSION ON INDUCTION OF HEPATOMA IN RATS FED 4-(DIMETHYLAMINO)-AZOBENZENE. (E.) Tsukada, Y. (Hokkaido U. Sch. Med., Japan). *Gann* 63(1):131-133, 1972.

Male Donryu rats were fed on a diet containing 0.06% 4-(dimethylamino)azobenzene (DAB) for 19 wks and given transfusions of blood from rats resistant to transplantation of ascites tumor one or more times/wk for 21 wks (Group 1). Other rats were fed DAB and given transfusions of blood from normal donors (Group 2), or were given either DAB and no transfusion (Group 3), or neither transfusion nor DAB (Group 4). Eleven of 30 Group 1 rats, 17 of 50 Group 2 rats, and 21 of 50 Group 3 rats developed hepatomas by 524 days after the start of the experiment. Thirty-five percent of transfused rats (Groups 1 and 2) developed hepatomas compared to a 43% hepatoma incidence in untransfused, DAB-fed rats.

2932 THE DEVELOPMENTAL, NODULIGENIC, AND TUMORIGENIC POTENTIALS OF TRANSPLANTED MAMMARY GLANDS AND PRIMARY DUCTS FROM C3H MICE PREVIOUSLY FED A PHENYLALANINE-DEFICIENT DIET. (E.) Hui, Y. H. (Cancer Res. Genetics Lab. U. California, Berkeley), K. B. DeOme and G. M. Briggs. *Cancer Res* 32(1):57-60, 1972.

Virgin female C3H/Crgl mice were fed diets containing deficient amounts of phenylalanine (0.90 or 0.120%) for 19-20 wk; half the mice in the phenylalanine-deficient groups were given pituitary isografts under the left kidney capsule. A control group was fed a stock diet and given no pituitary grafts. The phenylalanine-deficient mice served as donors of mammary gland tissue grafts to five wk old virgin C3H/Crgl mice (hosts). Hosts were given a whole-gland mammary transplant and two primary duct transplants. The whole inguinal mammary glands were sutured onto the abdominal body wall, and the primary duct transplants were transplanted into gland-free into gland-free inguinal fat pads. In addition, hosts received pituitary isografts. When host were 16-17 wk old, pituitary grafts were destroyed; mice were killed six wk later and the development of mammary glands, hyperplastic alveolar nodules and mammary tumors was observed. All but two of 130 whole-gland transplants, all outgrowths from transplanted primary ducts, and all host mammary glands, developed nodules, regardless of the dietary or hormonal status of transplant donors. Tumors did not develop in host glands or in outgrowths from primary duct transplants and whole-gland transplants taken from control donors. Thirty tumors developed in 214 whole-gland transplants and outgrowths from primary ducts taken from phenylalanine-deficient mice. Tumor incidence was higher in transplants taken from donors fed phenylalanine-deficient diets and stimulated by pituitary isografts than in transplants from phenylalanine-deficient unstimulated donors. Transplanted mammary glands and primary duct outgrowths were well developed and resembled host glands. Evidently, phenylalanine deficiency did not permanently impair the developmental noduligenic or tumorigenic capacities of donor mammary glands.

2933 THE INTERACTION OF (³H)ETHYL CARBAMATE WITH NUCLEIC ACIDS OF REGENERATING MOUSE LIVER. (E.) Lawson, T. A. (U. Queensland Sch. Med., Australia) and A. W. Pound. *Chem-Biol Interactions* 4(5):329-341, 1971/72.

The binding of urethane (ethyl carbamate) to liver nucleic acids of Crackembush mice was examined by observing levels of binding to DNA and RNA in liver regenerating after partial hepatectomy. Initially, 20 mg of unlabeled urethane were given to intact and partially hepatectomized mice, and DNA and RNA synthesis were observed. DNA and RNA synthesis were reduced in intact and in partially hepatectomized mice given urethane. Mitosis was also inhibited in liver cells by urethane. In urethane binding experiments, a single dose of 50 μ Ci ³H-urethane was given to four groups of mice: non-hepatectomized controls (group A), and mice hepatectomized 18, 28 and 38 hr before urethane treatment (groups B, C and D, resp.). Four to 16 hr after urethane, mice were killed and liver DNA and RNA were isolated and examined for radioactivity. Maximum specific activities for DNA were lower in hepatectomized than in intact mice; values for DNA activity in groups A, B, C and D, resp., were 130, 90, 72 and 39 mCi/g. Binding of urethane to DNA persisted longest in group B. Urethane binding to RNA was greater in hepatectomized than in intact mice. When three doses of labeled urethane were given to intact and hepatectomized mice (30, 150 and 300 μ Ci) binding to DNA varied with dose in the approximate ratio of 1:5:10. This suggested that it was not restoration of liver mass which was responsible for lower levels of urethane binding to DNA in groups B, C and D. Altered urethane metabolism did not appear to account for different levels of binding.

2934 INITIAL CELL CYCLE DELAY AND DEPRESSION OF MACROMOLECULAR SYNTHESIS OF PRIMARY MOUSE EMBRYO CELLS TREATED WITH METHYLNITROSOUREA IN MASS CULTURE. (E.) Frei, J. V. (Fac. Med., U. Western Ontario, London, Canada) and J. Oliver. *Exp Cell Res* 70(1):49-56, 1972.

Inbred Swiss CFW/D mouse embryo cell cultures were treated with 0.2 ml of methylnitrosourea (MNUA) in concentrations of 0.5-3.0 mM and the effect of MNUA on the cell cycle was observed. MNUA caused cells to proliferate less rapidly than untreated cells; this effect was due to a slowing down of the cell cycle, and not to cell killing. The slowing down of the mouse embryo cell cycle by MNUA was not associated with the entry of cells into the S phase; neither the G₁ nor the G₂ phases were affected by MNUA. MNUA treatment decreased the loss of cells from the monolayer culture, possibly by decreasing cell death. Macromolecular synthesis by mouse embryo cells was depressed by MNUA. At a 1.5 mM MNUA concentration, DNA synthesis in cells (as measured by ³H-thymidine uptake) was decreased by 78%, RNA synthesis by 56%, and protein synthesis by 72%. Depression of macromolecular synthesis by MNUA was approximately pro-

portional to MNUA dose. DNA synthesis in MNUA-treated cells remained depressed for three days. It is concluded that MNUA acts to delay proliferation of mouse embryo cells by prolonging the S phase of the cell cycle.

- 2935 THE EFFECT BOTH OF TIME AND DOSE APPLIED ON TUMOUR INCIDENCE RATE IN BENZOPYRENE SKIN PAINTING EXPERIMENTS. (E.) Lee, P. N. (Tobacco Res. Council Lab., Harlow Hill, England) and J. A. O'Neill. *Brit J Cancer* 24(4):759-770, 1971.

In two separate experiments using 1200 and 160 specific pathogen-free mice resp., mice were painted with benzo(a)pyrene (BP) in amounts of 6, 12, 24 or 48 g/wk, or with 1, 3, 9 or 27 g every fourth day. Tumor development was observed for 69 wk posttreatment. Figures on tumor incidence were subjected to statistical analyses to test the hypothesis that when a constant repetitive dose of carcinogen is applied to a target area, the incidence rate of tumors is proportional to $(t-w)^{k-1}$, where t is time and w and k are constants. A model in which the tumor incidence by BP is proportional both to $(t-w)^{k-1}$ and to $(\text{dose})^2$ showed a very good fit on the data yielded by the experiments.

- 2936 SCISSIONS OF PROTEINS LINKING DNA IN CULTURED MAMMALIAN CELLS INDUCED BY 4-NITROQUINOLINE 1-OXIDE AND THEIR REPAIR. (E.) Ide, T. (Inst. Med. Sci., U. Tokyo, Japan) and T. Andoh. *Cancer Res* 32 (6):1236-1242, 1972.

The rejoining of double-strand scissions of DNA induced by 4-nitroquinoline 1-oxide (4NQO) was studied in cultured mouse cells, strains FM3A and L-P3. FM3A cells were ten times more sensitive to the effects of 4NQO than were L-P3 cells, as 10^{-6} M 4NQO caused a decrease in the sedimentation rate of DNA of FM3A cells in sucrose gradients comparable to that caused by 10^{-5} M 4NQO in L-P3 cells. The scissions caused by a low 4NQO concentration in FM3A were completely re-joined on incubation for 24 hr in medium without 4NQO ("recovery incubation"). However, at 4NQO concentrations greater than 3×10^{-6} M, the extent of breakage increased and repair was incomplete after 24 hr. 4NQO-treated cells in which the DNA double-strand scissions had been repaired were able to grow at a rate comparable to that of untreated cells. However, as the unrepaired DNA fraction increased with increasing 4NQO concentrations, the viability of the cells decreased. It is suggested that the 4NQO-induced cell death was due to the irreparable damage to DNA. Treatment of cellular DNA with Pronase caused a decrease in the sedimentation rate equivalent to that caused by treatment of cells with 10^{-5} or 10^{-6} M 4NQO or that caused by treatment with Pronase plus 4NQO. This suggested that the site on DNA cleaved by Pronase was the same as that cleaved by 4NQO and further indicated that this site was a peptide linkage. Treatment of FM3A or L-P3 cells with higher concentrations of 4NQO resulted in a greater decrease in the sedimentation rate of DNA than treatment of control DNA with Pronase

alone, suggesting that the 4NQO had produced nucleotide breaks in addition to the peptide linkage breaks induced by lower concentrations.

- 2937 PRELIMINARY STUDIES OF TOLERANCE TO CONTACT SENSITIZATION IN CARCINOGEN-FED GUINEA PIGS. (A.) Pomeranz, J. P. (Case Western Reserve U. Sch. Med., Cleveland, Ohio). *J Nat Cancer Inst* 48(5):1513-1517, 1972.

Random bred male Hartley strain guinea pigs were fed 50, 75 or 100 mg 7,12-dimethylbenz(a)anthracene (DMBA) in 1.5 ml corn oil. Additional animals were fed 50 or 100 mg 3-methylcholanthrene (MCA) or benzo(a)pyrene (BP) in 2.5 ml and 5 ml corn oil resp. Three wk after ingestion, the recipients and controls (fed corn oil alone) were immunized with foot-pad injections of the same carcinogen (200 μ g DMBA, 300 μ g BP or 300 μ g MCA) mixed with Freund's complete adjuvant. Two wk later, all animals were tested for contact sensitivity by application of 0.1, 0.5 or 1.0% concentrations of the same carcinogens in acetone-olive oil, 4:1. Fifty percent of the DMBA-fed animals and 66% of the BP-fed recipients had negative or trace contact reactions to topical application of a 1% concentration of the same chemical in acetone-olive oil. In contrast, all controls showed cutaneous contact hypersensitivity to the carcinogen, even when more dilute concentrations were applied. Seventy-seven percent of the MC-fed animals showed no hypersensitivity response. All but one animal in all the experimental and control groups showed tuberculin sensitivity upon injection of purified protein derivative. The absence of a cutaneous hypersensitivity response in the experimental animals was comparable to the tolerant state induced by feeding simple chemical haptens, in terms of specificity and resistance.

- 2938 DELIMITATION OF INHIBITORY AND ENHANCING EFFECT OF HISTONE ON TUMOR GROWTH. (E.) Gillissen, G. (Med. Faculty, Technische Hochschule, Aachen, West Germany) and K. Schweizer. *Z Krebsforsch* 77:57-63, 1972.

The inhibitory and enhancing effects of unfractionated total histone extracted from calf thymus nuclei on the growth of two solid Ehrlich ascites tumors, EAT/Hoechst and EAT/Stol, were studied *in vivo*. Treatment of mice by s.c. injection of histone containing 100 μ g nitrogen daily for ten days, starting on the day of implantation of EAT/Hoechst, or treatment with 100 or 250 μ g histone-N on days 4, 5 and 6 after tumor implantation, either inhibited tumor growth by five-fold or caused regression of palpable tumors in 50% of the animals. The effect of histone on EAT/Stol under these conditions was not significant. The difference in susceptibility between the two growing tumors was attributed to a faster growth rate of the histone-sensitive EAT/Hoechst. Histone injection after day nine, when tumor growth rate had decreased, showed no effect on subsequent tumor growth. Pretreatment of

mice with six s.c. injections every other day of histone followed by implantation of EAT/Hoechst one wk after the last injection enhanced tumor growth by 50% compared with controls. This finding was consistent with the view that enhancement of tumor growth might be due to the previously demonstrated immunosuppressive effect of histone.

2939 SOME FACTORS INFLUENCING THE RESPIRATORY TOXICITY OF CIGARETTE SMOKE. (E.)

Dalhamn, T. (Inst. Hyg., U. Uppsala, Sweden). *J Nat Cancer Inst* 48(6):1821-1824, 1972.

The toxicity of cigarette smoke was determined on the secretion-transporting mechanism of the respiratory tract as reflected in ciliary movements. Previously published results showed that with greater volumes of inhaled cigarette smoke, fewer inhalations were required to inhibit ciliary movement in cats. With a constant inhalation volume, longer intervals between inhalations produced smaller toxic effects. Cats exposed to inhalations from cigarettes with cellulose acetate filters or carbon filters required approximately twice as many inhalations to produce ciliostasis as did cats exposed to inhalations from standard nonfilter control cigarettes. In the experiments reported on in this paper, eight different types of cigarettes were smoked by cats. Statistical analysis showed that ciliotoxicity was best correlated with the content of tar which explained 52.5% of the variation in toxicity. Acrolein was the only other component of cigarette smoke which showed a significant degree of correlation with ciliotoxicity. Nicotine, acetaldehyde, carbon monoxide, hydrogen cyanide, nitrogen oxides and pH of the smoke had no apparent effect. Experiments indicated that all substances analyzed were retained to a far greater extent in the lungs than in the mouth.

2940 CARCINOGENICITY OF 7H-DIBENZO[c,g]CARBAZOLE IN THE RESPIRATORY TRACT OF HAMSTERS. (E.)

Sellakumar, A. (U. Nebraska Med. Ctr., Omaha) and P. Shubik. *J Nat Cancer Inst* 48(6):1641-1646, 1972.

Male Syrian golden hamsters received either 15 or 30 weekly intratracheal installations of 7H-dibenzo[c,g]carbazole (7H-DBC) suspended with an equal volume of hematite in saline. A third group served as untreated controls. In the group treated for 15 wk (45 mg 7H-DBC total), 30 of 35 animals at risk (86%) had respiratory tract tumors. Fifty percent of the tumors were squamous cell carcinomas, with the first tumors appearing in the bronchus as early as the 15th wk. The hamsters treated for 30 wk (15 mg 7H-DBC total) had an 89% incidence of respiratory tract tumors (40 of 45 animals at risk). In this group, 64% of the animals bore a total of 51 squamous cell carcinomas, with the first tumors appearing in the trachea at the 30th wk. Other tumors induced in both groups included adenocarcinomas, anaplastic carcinomas, adenomas, papillomas, polyps and fibrosarcomas. Most tumors in both groups arose from the epithelium of the bronchi and trachea; a few arose in the larynx. No other tumors were seen except for

papillomas of the forestomach. Although the respiratory tract tumors did not metastasize into other organs, the bronchogenic carcinomas did metastasize as small nodules into the lungs. No tumors were seen in the control group.

2941 PREFERENTIAL BINDING OF 2-ACETYLAMINOFLUORENE TO RAT LIVER rRNA DURING EARLY STAGES OF HEPATOCARCINOGENESIS. (E.) Irving, C. C. (VA Hosp., Memphis, Tennessee) and R. A. Veazey. *Biochem Biophys Res Commun* 47(5):1159-1164, 1972.

The binding of 2-acetyl-amino-fluorene-9-¹⁴C (AAF-¹⁴C) to different nucleic acid moieties was studied in partially purified rat liver homogenates. AAF had been shown to induce a high incidence of liver tumors in male rats. In one series of experiments male and female Holtzman rats were fed a grain diet containing 0.04% AAF-¹⁴C. Binding of AAF-¹⁴C to liver DNA was the same (300-400 pmoles/mg) for both sexes although a maximum was reached faster in male rats. Binding to tRNA was transitory in male rats reaching a maximum of 200-250 pmoles/mg by three days and declining rapidly thereafter with a half-life of 1.5 days. The most significant sex difference was observed in the amount of AAF-¹⁴C bound to liver rRNA. In male rats, rRNA specific activity increased to 350 pmoles/mg by two wk and fell gradually thereafter with a half-life of three days. Liver rRNA specific activity of female rats increased very slowly and reached a maximum value of only 100-150 pmoles/mg at 4-8 wk. Simultaneous administration of 3-methylcholanthrene (0.005%), which was previously shown to inhibit AAF tumor induction in male rats, resulted in a 35-40% decrease in binding of AAF-¹⁴C to liver rRNA and DNA as opposed to a 50% increase in the binding of carcinogen to liver tRNA. These data support the concept that binding of AAF to liver rRNA, but not to liver tRNA, might be involved in hepatocarcinogenesis.

2942 HORMONAL CARCINOGENESIS WITH SPECIAL EMPHASIS ON THE INDUCTION OF MAMMARY TUMOURS IN MICE. (E.) Boot, L. M. (Netherlands Cancer Inst., Amsterdam). *Rev Roum Endocrinol* 8(3):225-228, 1971.

Three model systems are described in which excessive hormone production has definitely been associated with the induction of neoplasms. The first and simplest system involves the induction of thyroid tumors by disturbing the normal inhibition of TSH production by the hypophysis. Such procedures as subtotal thyroidectomy, iodine deficiency, or treatment with goitrogenic drugs lead to excess TSH release which in turn stimulates the thyroid producing hyperplasia and, ultimately, neoplasia. The second example, the induction of ovarian tumors, is almost as simple and also involves disturbance of the hypophyseal feedback mechanisms. When an ovary or a part of an ovary is transplanted to the spleen, the estrogens produced by the ovary are metabolized by the liver and do not reach the hypophysis. This results in excessive production

of FSH and LH which leads to abnormal growth of the ovarian graft and ultimately, again, to tumor formation. Of the two hormones, LH appears to be the more important as treatment with anti-LH, but not anti-FSH, serum prevents tumor formation. The third system, the induction of mammary tumors in female mice, also involves the pituitary feedback system but the mechanism is more complex than that of the first two systems. In this system, the hypophysis is transplanted to a site (the kidney) away from the sella turcica. The leads to uninhibited production of prolactin, an excess of progesterone, and the induction of mammary tumors. FSH and LH are not produced and are apparently not involved in this system. The degree of mammary tumor response depends on the mouse strain or hybrid used, the site and number of pituitaries implanted, and the age and sex of the donors.

- 2943 BLASTOMOGENESIS IN RATS WITH PERSISTENT ESTRUS. (Rus.) Anisimov, V. N. (N. N. Petrov Res. Inst. Oncol., Leningrad, USSR). *Vop Onkol* 17(8):67-75, 1971.

Tumor development in persistent estrus associated with estrogen deficiency, and the effect of such a state on tumorigenesis induced by 20-methylcholanthrene (MC) were studied in four groups of white hybrid female rats: 68 normal virgin rats (Group I), 66 virgin rats with constant estrus induced by auto-transplantation of the ovary in the tail after castration (Group II), 27 virgin rats with persistent estrus induced by the same method and which received MC in peach oil (5-10 mg i.p. for 30-35 days six times a week) starting five weeks after the operation (Group III), and 26 intact virgin rats which received the same dose of MC in peach oil (Group IV). The rats were 6-16 months old. The rats were autopsied for microscopic examination of tumor growths 6-36 months after the beginning of the experiment. Tumors developed more in Group II (43/66) and Group III (10/27) than in the control group (18/68). The number of malignant tumors was higher in Group II (17) and Group III (5) than in the control (3/68). Adenocarcinoma of the uterus was observed in Group II (1) and Group III (1), while it was not seen in the other two groups. The concentration of follicle stimulating hormone in the pituitary increased and excretion of total estrogens decreased with age in intact rats. Analogous age variations were seen in rats with persistent estrus, but they were more pronounced. MC induced a similar number of tumors in Group III and Group IV, but the incidence of multiple neoplasms was higher in Group IV (5/26) than in Group III (2/27). In animals with persistent estrus, MC did not induce mammary tumors, but it increased the incidence of mammary fibroadenoma (20) and adenocarcinoma (8) in rats with normal estrus. MC administered to rats with normal estrus inhibited pregnandiol and total estrogen excretion, increased 17-ketosteroid excretion with no change in plasma corticosterone level. MC did not cause adrenal dysfunction in operated rats with persistent estrus, which showed an increase in 17-ketosteroid excretion associated with an increase in the plasma corticosterone level. Thus, combined per-

sistent estrus and MC suppressed tumorigenesis in the mammary gland, while adrenal dysfunction accelerated tumor growth in the mammary gland.

Therefore, anovulation is an important factor in development of mammary tumors in rats exposed to exogenous and endogenous tumorigenic agents.

- 2944 A MODEL OF EXPERIMENTAL REPRODUCTION OF CANCER OF THE ESOPHAGUS. (Rus.) Litvinov, N. N. (No affiliation), V. I. Govershenko and V. N. Kurylev. *Bull Exp Biol Med* 72(8):84-87, 1971.

N,N'-dimethylethylenedinitrosamine (5 mg/kg in aqueous solution) was introduced by catheter into the esophagi of 105 white male rats daily except Sundays for four months, and five rats were autopsied at monthly intervals of 1-4 months from the beginning of the experiment; 17 rats died in 2-6 months; and the remaining 68 animals were autopsied 5 or 6 months from the beginning of the experiment. Microscopic examination showed no changes in the esophagi from the animals killed after one month. In all five animals killed after two months, there was diffuse-focal thickening of the esophageal mucosa due to an increase in epithelial cell layers and intense keratosis. In animals killed after three months, leukoplakia was present due to hyperplastic epithelium, increased cell growth, and hyperkeratosis. These hyperplastic changes were more intense in animals killed after four months. In addition, the following changes were observed: papillomatous growths in the connective tissue; epithelial cell proliferation in the submucous membrane, infiltrating the connective tissue; benign epithelial cell tumors; and active growth of epithelial cells in a tumor growing from a thin peduncle. In animals studied after five and six months the tumors were larger and were typical squamous cell carcinomas which were frequently keratinized. Primary neoplasms and metastases were not observed in other organs. Multiple carcinomas of the esophagus associated with papillomatosis were observed in all 75 animals examined after 5-6 months.

- 2945 INCREASED ACTIVITY OF POLYNUCLEOTIDE LIGASE FROM RAT HEPATOMA INDUCED BY N-2-FLUORENYL-ACETAMIDE. (E.) Tsukada, K. (Fac. Pharm. Sci., Toyama U., Japan), S. Hokari, N. Hayasaki and N. Ito. *Cancer Res* 32(5):886-888, 1972.

Nonhepatoma and hepatoma areas of liver are studied for polynucleotide ligase activity. Wistar male rats were fed for three months on a diet containing 0.025% N-2-fluorenylacacetamide (2-FAA). Rats were maintained an additional three months following 2-FAA treatment on a diet without 2-FAA. Enzyme activity was measured in purified liver nuclei and nuclear extract by the conversion of 5'-phosphomonoesters-³²P in nicked DNA into a form which remained acid insoluble after incubation in alkaline phosphatase. ATP, Mg²⁺ and mercaptoethanol were required for enzyme activity. ATP could not be replaced by NAD⁺ in either normal rat liver or hepatoma. Mn²⁺ could not replace Mg²⁺.

The enzyme was inactivated by P-chloromercuribenzoate in the absence of mercaptoethanol. The activity of ligase in the soluble fraction from rat hepatoma (0.268 ± 0.030 μ moles phosphatase-resistant 32 P/mg protein) was five times greater than that in normal rat liver (0.046 ± 0.005). Ligase activity in the nuclear extract from rat hepatoma (1.40 ± 0.20) was about three times that in normal rat liver (0.48 ± 0.05). These differences were not caused by differences in the contamination by nucleases in the enzyme preparations. In normal liver about 50% of the ligase activity was localized in the nuclear fraction and 40% in the cytoplasm, while in hepatoma about 30% of the ligase activity was nuclear and 60% was cytoplasmic.

2946 SELECTIVE INHIBITION OF RNA POLYMERASE ACTIVITY IN RAT LIVER NUCLEI BY 4-(DIMETHYLAMINO)AZOBENZENE, AND EFFECT OF NITROFURANS ON LIVER RNA METABOLISM ASSOCIATED WITH PREVENTION OF CARCINOGENESIS. (E.) Akao, M. (Inst. Food Microbiol., Chiba U., Japan), K. Kuroda and K. Miyaki. *Gann* 63(1):1-10, 1972.

To investigate the mechanism of the reduction of liver RNA by 4-(dimethylamino)azobenzene (DAB), male Donryu rats were fed diets containing 0.06% DAB; other rats were fed diets containing DAB and either 2-(2-furyl)-3-(5-nitro-2-furyl)acrylamide (N1) or 2-amino-5-(2-(5-nitro-2-furyl)-1-(2-furyl)-vinyl-1)-1,3,4-oxadiazole (N2). The latter agents are nitrofurans which inhibit liver carcinogenesis induced by DAB. Quantities of liver RNA and DNA were determined in rats fed DAB for 5, 10 and 15 days. The DAB diet decreased the RNA content/g liver and the RNA/DNA ratios of liver significantly. RNA/DNA ratios were little changed in rats fed DAB plus N1 or N2. Studies were made to determine whether accelerated RNA degradation or suppressed RNA synthesis accounted for the decrease in liver RNA in DAB-fed rats. The half-life of 14 C-RNA in rat liver cells was used to measure RNA degradation. 14 C-RNA's half-life was not shortened by DAB feeding. The analysis of liver for RNA synthesis was made by estimating two kinds of DNA-dependent RNA polymerase in isolated liver cell nuclei: Mg^{2+} -activated and Mn^{2+} -(NH_4) $_2$ SO $_4$ -activated RNA polymerase. The Mn^{2+} -(NH_4) $_2$ SO $_4$ -activated RNA polymerase was suppressed by 35% in rats fed DAB for ten days. Mg^{2+} -activated RNA polymerase was stimulated by DAB. N1 and N2, fed concurrently with DAB, increased both RNA polymerases in rat liver. The decrease of liver RNA by DAB was apparently caused by RNA polymerase suppression by DAB; nitrofurans apparently antagonized the action of DAB on liver RNA by increasing RNA polymerase activity.

2947 EFFECT OF MALE HORMONE ON CHEMICALLY INDUCED SKIN CANCER IN MICE. (Fr.) Derout, J. (Bouicaut Hosp., Paris, France), G. Thieriot-Prevost and J. de Brux. *C R Acad Sci (Paris)* 165 (3):520-523, 1971.

Of 90 male C57BL/Gif mice, 30 normal ones received a

single injection of Androtardyl (testosterone 100 μ g i.p.) in olive oil and were subjected to weekly skin painting with methylcholanthrene (MC) in mineral oil, 30 were subjected to castration + MC, and 30 intact mice received only MC. Mice treated with Androtardyl developed tumors somewhat earlier (after 12 weeks) than the others, but these tumors were highly differentiated, keratinized papillomas which only became malignant about 17 weeks after initiation of treatment. These tumors resemble the relatively benign verrucose laryngeal carcinomas found in man. Intact mice treated with MC alone developed invasive, highly differentiated epidermoid tumors after 16 weeks, while castrated mice given MC developed moderately differentiated, rapidly infiltrating tumors of the same type after 14 weeks. These findings indicate that male hormone has a significant effect on tumor differentiation but has very little effect on the time at which malignant tumors appear.

2948 OESTRADIOL RECEPTORS IN CARCINOMA AND BENIGN DISEASE OF THE BREAST: AN *IN VITRO* ASSAY. (E.) Feherty, P. (Middlesex Hosp. Med. Sch., London, England), G. Farrer-Brown and A. E. Kellie. *Brit J Cancer* 24(4):697-710, 1971.

Supernatant fractions of homogenates of breast tumor biopsies were tested by an *in vitro* assay for the presence of specific, high-affinity receptors which could bind 3 H-labeled estradiol. The method was applied to biopsies from 94 patients with malignant and benign disease of the breast. Of the 53 biopsies classified as carcinomas, 37 contained high-affinity estradiol receptors in concentrations ranging from 0.3 to 22.6×10^{-15} moles/mg tissues, two were "borderline", and 14 had no receptor. The proportion of positive results and the range of concentrations were found to be somewhat higher in postmenopausal than in premenopausal patients. Despite detailed examination, no histological feature was found which could explain the variation in receptor concentration; neither could it be accounted for by differences in the cellularity of the biopsies (expressed as total DNA content). Of the 41 benign breast biopsies examined, only three contained any high-affinity estradiol receptor, and in these the concentration was very low (0.3 to 0.6×10^{-15} moles/mg tissue). The receptor was not detected in normal breast tissue.

2949 INTRACELLULAR DISTRIBUTION OF *IN VIVO* LIVER CATALASE-DEPRESSING SUBSTANCE IN RHODAMINE SARCOMA. (E.) Kannan, Y. (Inst. Protein Res., Osaka U., Japan), K. Nishikawa, Y. Matuo and T. Horio. *Gann* 63(2):201-208, 1972.

Nuclear, mitochondrial, microsomal and supernatant fractions of rat Rhodamine sarcoma tissue were assayed in an attempt to localize the liver catalase-depressing ("toxohormone") activity previously reported. Of all fractions, the nuclear one

possessed the highest liver catalase-depressing activity when injected into mice. Depressing activity of the mitochondrial and microsomal fractions was less than that of the nuclear fraction. The supernatant fraction contained no activity. Assays performed on nucleolar and chromatin fractions of purified sarcoma nuclei showed that the catalase-depressing activity was only associated with the latter. Although catalase-depressing activity was also found in cell homogenates of dorsal muscle and liver of normal rats, the extent of depression was much lower than that of Rhodamine sarcoma tissues. Fractions prepared from tumor tissues freshly obtained had a significantly lower activity than those prepared from tumor tissues stored frozen.

- 2950 HORMONAL CARCINOGENESIS GROWTH OF HYPOPHYSEAL ISOGRAFTS AND THE INDUCTION OF MAMMARY TUMOURS IN MICE. (E.) Röpcke, G. (Netherlands Cancer Inst., Amsterdam). *Rev Roum Endocrinol* 8(3):229-232, 1971.

The effects of estrogens and progesterone were studied on hypophyseal isograft growth and mammary tumor induction in various mouse strains and hybrids. Pituitary isografts to the left kidney were performed in 6-to-8-wk-old mice. Isografts grew in intact mice to a wt of 4000 mg or more within two yr. Ovariectomy drastically reduced graft growth. Isograft growth was restored by treatment of castrate females with estrogen, but not with progesterone. Estrogen also stimulated graft growth in castrate males. Castrate male (C57BL x CBA)F₁ mice bearing isografts were fed different concentrations of estrone or estrone plus progesterone (0.0125 to 2.00 mg/l) in their drinking water. Although no dose-response relationships could be established, all types of estrogen administered (high and low doses as well as discontinuous treatment at 5-day intervals) induced substantial growth of the isografts. Mammary tumor incidences obtained with estrone treatment alone were correlated more with isograft growth than with the estrogen dose given. These results indicated that estrone was acting by stimulating production of prolactin by the pituitary isografts. Progesterone appeared to act directly on the mammary gland, in synergism with prolactin, increasing the mammary tumor incidence and decreasing the average age of tumor-bearing mice.

- 2951 NITROSAMINE STUDIES: NEOPLASMS OF LIVER AND GENITAL MESOTHELIUM IN NITROSOPYRROLIDINE-TREATED MRC RATS. (E.) Greenblatt, M. (U. Nebraska Coll. Med., Omaha) and W. Lijinsky. *J Nat Cancer Inst* 48(6):1687-1696, 1972.

Male and female MRC (Wistar-derived) rats were fed nitrosopyrrolidine (NP), a cyclic nitrosamine, in their drinking water (total dose of 1,340 mg) for 7 wk. After cessation of treatment, animals were observed for 105 wk and survivors were sacrificed and autopsied. Seventy untreated animals served as

controls. Hepatocellular carcinomas were induced in all 25 rats treated with NP. They were the only tumors found in females and were usually large, solitary, well-defined masses. According to the Broder classification, 16 of 25 (64%) were grade 1-2 and 9 of 25 (36%) were grade 3-4. There was little overall variation in histologic grade within each tumor and uninvolved liver tissue was essentially normal in 20 of 25 (80%) of the tumor-bearing rats. Vascular invasion of the hepatic venous circulation was present in 12 of 25 (48%) of the tumor-bearing rats but was not invariably associated with distant metastases (lung, lymph nodes) which were seen in only 6 of 25 (24%) animals. In addition, genital tumors occurred in 7 of 12 male rats, and four of these were papillary mesotheliomas of the tunica vaginalis testis, a histologic type rarely described in MRC rats. Two of the four animals with papillary mesotheliomas had associated interstitial cell tumors. A review of the literature with respect to the carcinogenic activity of nitroso compounds and their possible relationship to human neoplasia is presented.

- 2952 THE EFFECT OF VARIATION IN CARCINOGENIC DOSAGE ON THE INDUCTION OF TUMOURS IN THE DORSAL AND VULVAL SKIN OF FEMALE RATS. (E.) Glucksmann, A. (Strangeways Res. Lab., Cambridge, England) and C. P. Cherry. *Brit J Cancer* 24(4):735-745, 1971.

The response to 5, 10, 20 or 40 weekly paintings with 9,10-dimethyl-1,2-benzanthracene (DMBA) of the dorsal and vulval skin in intact and castrate rats is compared. Squamous and basal cell tumors appeared faster in the dorsal skin than in the vulval region with 5, 10 or 20 paintings, but at the same rate with 40 doses. The rate of induction of epithelial tumors was optimal with 20 applications dorsally, but increased with dose at the vulva. Progression of malignancy of squamous cell tumors was greater and faster in the dorsal than in the vulval region. For basal celled neoplasms of the vulva there was a peak value in malignant conversion at 20 doses, but otherwise there was no consistent difference in the pattern at the two sites. Castration reduced the incidence of basal cell tumors of the vulva in rats painted weekly for life, but did not affect the incidence of epithelial tumors of the skin. Sarcomas occurred in 29% of rats in the dorsal region, but in only 0.4% at the vulva. Sarcomatous changes in the stroma of epitheliomas were also more frequent in the dorsal skin. Local factors rather than variation in individual sensitivity accounted for the differences with region in the carcinogenic response as shown by their persistence in rats treated simultaneously at both sites.

- 2953 STUDIES ON THE BINDING AND DISTRIBUTION OF RADIOACTIVELY LABELLED 3'-METHYLCHOLANTHRENE IN SUBCELLULAR FRACTIONS OF RAT LIVER. (E.) Jones, P. A. (Dept. Biochem., U. Rhodesia,

Salisbury) and A. O. Hawtrey. *Brit J Cancer* 24(4): 45-852, 1971.

The subcellular distribution of [^{14}C] or [^3H] 3'-methylcholanthrene (3-MC) was studied in liver from male albino rats ten hr after administration of a single i.p. injection of the labeled hydrocarbon. Subcellular fractions were obtained by ultracentrifugation of the liver homogenates. Experiments showed that 3-MC which was non-covalently bound was highly prevalent and was associated with protein and not with t-RNA. Covalently bound radioactivity occurred to a small extent and was not considered significant. Washed mitochondria (25% incorporation), washed microsomes (20%) and cell sap (52%) accounted for the main binding of labeled 3-MC of its metabolites in rat liver. Highly purified cell wall membranes had no radioactivity associated with them. Purified nuclei possessed only 2% of incorporated radioactivity. Fractions with the highest labeling in terms of specific activity (dpm/mg protein) were the washed mitochondria, washed microsomes and washed ribosome-free microsomal membranes and the core proteins from these fractions. Fractionation of the cell sap into pH 5 enzyme and pH 5 supernatant indicated that the specific activity of the pH 5 enzyme was about four times higher than that of the pH 5 supernatant. Further fractionation of the pH 5 enzyme by $(\text{NH}_4)_2\text{SO}_4$ precipitation indicated that the 0-30% fraction contained the highest specific activity.

2954 N-NITROSAMINES IN SMOKE CONDENSATE FROM SEVERAL VARIETIES OF TOBACCO. (E.) Johnson, D. E. (Southwest Res. Inst. San Antonio, Texas) and J. W. Rhoades. *J Nat Cancer Inst* 48(6): 845-1847, 1972.

Smoke condensate collected by impingement from experimental cigarettes made from unblended tobaccos (Robinson, Catterton or Burley) supplied by the U.S. Department of Agriculture was analyzed by gas chromatography for N-dimethylnitrosamine (DMNA) content. DMNA content was consistently lower (0-5 ng/cigarette) in smoke from cigarette made from tobacco grown in "low"-nitrogen soil than in smoke from cigarettes made from the same tobaccos grown in "high"-nitrogen soil (27-140 ng/cigarette). Smoke condensate from a popular brand of U.S.-nonfilter cigarettes contained 8 ng DMNA/cigarette. A second peak seen in gas chromatograms of condensate was present in much smaller quantities than DMNA and was tentatively identified as N-methylethyl-nitrosamine.

2955 N-DIMETHYLNITROSAMINE IN TOBACCO SMOKE CONDENSATE. (E.) Rhoades, J. W. (Southwest Res. Inst., San Antonio, Texas) and D. E. Johnson. *Nature* 236(5345):307-308, 1972.

Gas chromatographic analysis of cigarette smoke condensates showed two peaks with retention times identical to N-dimethylnitrosamine (DMN) and N-methylethyl-nitrosamine (MEN) on two different

column packings. The presence of DMN in the major peak was confirmed by high resolution mass spectroscopy. Analysis of DMN content of U.S.D.A. experimental cigarettes made from three different tobacco varieties showed that DMN content was consistently high (27-140 μg /cigarette) in cigarettes made from tobacco grown in soil containing a high nitrogen level. DMN content of cigarettes made from the same varieties of tobacco grown in low nitrogen soil was low (0-5 μg /cigarette). DMN content of a popular non-filter cigarette was 8 μg .

2956 EFFECT OF VARIOUS ESTROGENS ON THE INDUCTION OF LIVER CANCER IN MALE RATS TREATED WITH p-DIMETHYLAMINOAZOBENZENE (DAB). (Fr.) Lacassagne, A. (Radium Inst., Paris, France), M.-F. Jayle, L. Hurst and S. de Lauzon. *C R Acad Sci [D] (Paris)* 274(6):970-972, 1972.

In male Wistar rats given 600 mg/kg p-dimethylaminoazobenzene (DAB) in their food, simultaneous addition of 20 mg/kg estradiol or 20 mg/kg 6-ketoestradiol had no effect on DAB-induced liver cancer, whereas addition of ethinyl estradiol in much lower doses (2 and 4 mg/kg) inhibited liver cancer but caused weight loss, atrophy of the testes, seminal vesicles, and prostate, and interrupted spermatogenesis 37 days after institution of treatment. Liver necrosis and cirrhosis developed in some of these rats, but none had any malignant tumor nodules. Simultaneous administration of DAB + 2-methoxyestradiol (20 mg/kg) accelerated the development of multiple liver tumors which appeared five months after institution of treatment; this compound has minimal estrogen activity and had no effect on the testes or on spermatogenesis. In rats given DAB + 3,17 β -dimethoxyestratriene (20 mg/kg) in their food, primary liver carcinomas did not appear until 291 days later and no multiple tumors were found in these animals. The three rats sacrificed 330-351 days after treatment was begun had only nonmalignant liver changes. These findings suggest that compounds with estrogen activity inhibit the formation of DAB-induced liver tumors since they are not metabolized by enzymes in the liver.

2957 THE ACTION OF TWO ALKALOIDS, FUNTUMINE AND IREHDIAMINE A ON p-DIMETHYLAMINOAZOBENZENE (DAB)-INDUCED LIVER CANCER IN THE RAT. (Fr.) Lacassagne, A. (Radium Inst., Paris, France), L. Hurst, N. Dat-Xuong, Q. Khuong-Huu and R. Goutarel. *C R Acad Sci [D] (Paris)* 274(20):2830-2832, 1972.

Adult male Wistar rats were fed a diet containing p-dimethylaminoazobenzene (DAB; 0.60 g/kg food) with or without funtumine or irehdiamine A dihydrochloride (IDA; 0.05 g/kg food). Multiple liver tumors were found after 145 days in rats given DAB alone, after 186 days in rats given DAB + funtumine, and after 134 days in rats given DAB + IDA. Neither of these aminosteroids inhibited the growth of DAB-induced liver tumors, but IDA did accelerate

the later stages of tumor development. Peritoneal metastases developed in 2/10 rats given DAB + IDA. Administration of IDA alone for 188 days caused no abnormalities in the weight or structure of the liver. It is concluded that IDA potentiates the carcinogenic effect of DAB in the rat liver.

- 2958 INDUCTION OF HAMSTER TUMORS OF THE URINARY BLADDER BY 3,2'-DIMETHYL-4-AMINOBIIPHENYL.
(E.) So, B. T. (Amer. Hlth. Fdn., New York, N.Y.) and E. L. Wynder. *J Nat Cancer Inst* 48(6):1733-1738, 1972.

3,2'-dimethyl-4-aminobiphenyl (3,2'-DMAB) was administered s.c. once a wk at a dose of 100 mg/kg body wt to male and female Syrian golden hamsters. Of 20 hamsters which lived over 158 days, 15 (12 females and 3 males) developed bladder tumors. In addition, two adenocarcinomas of the colon, one malignant lymphoma, two mammary carcinomas, four granulosa-theca cell tumors of the ovaries, and one squamous cell carcinoma of the skin were found. The mean cumulative doses and days required for induction of bladder tumors were 2400-2700 mg/kg body wt (360-405 mg/animal) and 260-310 days. No local sarcomas were induced at the site of injection.

- 2959 COMPARISON OF SOME BIOLOGICAL EFFECTS OF STERIGMATOCYSTIN AND AFLATOXIN ANALOGUES ON PRIMARY CELL CULTURES. (E.) Engelbrecht, J. C. (Natl. Inst. Nutritional Dis., Pretoria, South Africa) and B. Altenkirk. *J Nat Cancer Inst* 48(6):1647-1655, 1972.

The toxicity of 15 analogous compounds, related to either sterigmatocystin or aflatoxin B₁, was evaluated on a primary cell culture system. Confluent primary kidney epithelial cell cultures of *Cercopithecus aethiops* were exposed to the various compounds (2 mg/l) for 24 hr after which time the cells were fixed and stained. In addition, the effects of these compounds on nucleolar morphology, mitosis, and incorporation of ³H-thymidine and ³H-uridine were studied. Structurally, the 15 compounds were divided into three groups manifesting toxic patterns which indicated a correlation between toxicity and structure. Compounds with an unsaturated $\Delta^{1,2}$ -furo-benzofuran system caused marked nucleolar changes and all completely inhibited mitosis after 24 hr. These compounds differed in their toxic effect on the nucleoli, sterigmatocystin I and aflatoxin B₁ being the most toxic. Compounds with a saturated $\Delta^{1,2}$ -furo-benzofuran system were much less toxic and produced only negligible nucleolar changes. Only dihydrosterigmatocystin markedly inhibited mitosis. Open-ring-furobenzofuran compounds had no apparent effect on mitosis or nucleolar morphology. The compounds with an unsaturated $\Delta^{1,2}$ -furobenzofuran were the most potent inhibitors of ³H-thymidine and ³H-uridine uptake, followed by the other two groups in the same order in which they showed toxicity and inhibition of mitosis. The results indicate that compounds which markedly

affect nucleoli also inhibit mitosis completely and most actively prevent the incorporation of ³H-thymidine and ³H-uridine. Increased toxicity was associated with a methoxy group at position C-6. It is suggested that compounds containing an unsaturated bond in the $\Delta^{1,2}$ -position and a carbonyl group that is unsaturated in the $\Delta^{1,2}$ position are required for carcinogenicity in this group of compounds.

- 2960 HISTOGENESIS AND AUTORADIOGRAPHY OF ADENOCARCINOMA OF THE GLANDULAR STOMACH IN RATS INDUCED BY ORAL ADMINISTRATION OF N, N'-2,7-FLUORENYLENEBISACETAMIDE COMBINED WITH IRRADIATION TO THE STOMACH REGION. (E.) Nagayo, T. (Aichi Cancer Ctr. Res. Inst., Japan), M. Ito and S. Yamada. *Gann* 63(2):143-151, 1972.

X-rays (500 R/wk) were directed to the stomach region of 28 male and female young adult Buffalo strain rats for 20 wk during ingestion of a diet containing 0.025% N,N'-2,7-fluorenylenebisacetamide (2,7-FAA). Control groups received either irradiation alone or 2,7-FAA alone. Five wk after the last irradiation, surviving animals were sacrificed and their stomachs were examined histologically. Neoplasms were induced with high frequency in the glandular stomach of all experimental groups and were classified into three categories: Type A (composed of immature atypical tubules), Type B (adenocarcinoma-like growths) and Type C (adenocarcinomas). Most of the 21 rats studied showed more than one of the histologic types. When diagnosis of adenocarcinoma was limited to Type C, frequency of induced carcinoma was 28.6% (6/21). Type B neoplasms were found in 57.1% (12/21) and Type A in 81.0% (17/21) of the experimental rats. No neoplasms were observed in 24 rats of the two control groups. Severe atrophy of the glandular mucosae and intensely heterotopic adenomatous growth in the proximal ends of the duodenum were consistently found in the rats receiving both X-irradiation and 2,7-FAA. Since gradations between the three histologic types were consistently observed, it was assumed that the appearance of immature tubules in the severely atrophic mucosa was the initial change in malignant transformation. The labeling patterns of cells in normal and neoplastic gastric glandular tissues were compared one hr after i.p. injection of ³H-thymidine. Although labeled cells in normal tissue were always found regularly in the transitional zone between foveolar epithelium and glandular tissues, labeled cells were diffusely scattered among all neoplastic tissues. Abnormality of distribution and frequency of labeling were least in Type A neoplasms and greatest in Type C.

- 2961 ON THE BINDING OF BENZ(a)PYRENE TO DNA IN VIVO. (E.) Carlassare, F. (U. Padova, Italy), C. Antonello, F. Baccichetti and P. Malfer. *Z Naturforsch* 27(2):200-202, 1972.

Male and female NVL mice were given a single oral

ose of ^3H -benz(a)pyrene. The mice were sacrificed after 15 hr and the amount of label was determined by scintillation spectrometry in DNA samples extracted from skin, spleen and liver. Calculations indicated that one molecule of benz(a)pyrene was bound to every 6.8 molecules of liver DNA, every 101 molecules of skin DNA, and every 168 molecules of spleen DNA. The relatively high specific activity of liver DNA samples suggested that covalent binding of benz(a)pyrene to liver DNA took place.

962 SMOKING AND LARYNGEAL CANCER. (E.) Stell, P. M. (Dept. Otolaryngology, U. Liverpool, England). *Lancet* (7751):617-618, 1972.

The smoking habits of 190 male and female patients with laryngeal squamous-cell carcinomas seen between 1965 and 1971 were compared with those of age and sex matched controls. There were fewer non-smokers and more heavy (11 or more cigarettes/day) smokers among the carcinoma patients than among the controls ($P < 0.001$). Only 13% of the patients were non-smokers or ex-smokers (stopped within the last yr), compared with 41% of the controls. A review of the literature showed that, although tobacco consumption and the incidence of lung cancer have risen sharply over the past 70 yr, the incidence of laryngeal cancer has remained more or less constant. It is suggested that any data showing a correlation between heavy cigarette smoking and laryngeal cancer must be interpreted with caution.

963 METABOLIC CONTROLS IN PRECANCEROUS LIVER: DEFECTIVE CONTROL OF CHOLESTEROL SYNTHESIS IN RATS FED N-2-FLUORENYLACETAMIDE. (E.) Horton, J. (Waite Agric. Res. Inst., U. Adelaide, South Australia) and J. R. Sabine. *Europ J Cancer* 7:459-465, 1971.

The synthesis of cholesterol from ^{14}C -acetate in liver slices was measured from rats fed the hepatocarcinogen, N-2-fluorenylacetamide (FAA). Within 3 wk of beginning FAA feeding (a) cholesterol synthesis was increased (b) feedback control of cholesterologenesis was partially or completely lost, (c) cholesterol synthesis was extremely variable within all groups fed FAA. Feedback control was regained within 16 wk in the liver, but remained ineffective in the hyperplastic nodules present on some livers at that time. It is suggested that loss of feedback control is an essential step in tumor development.

964 INHIBITION OF CHEMICAL CARCINOGENESIS BY VIRAL VACCINES. (E.) Whitmire, C. E. (Microbiol. Assoc., Bethesda, Md.) and R. J. Huebner. *Science* 177(4043):60-61, 1972.

Studies were undertaken to determine whether type C RNA virus vaccines would inhibit induction of sarcoma by 3-methylcholanthrene (3MC) in female weanling

BALB/cCr and C57BL/6 Cum mice. Vaccines were made by inoculation of mice with inactivated Rauscher leukemia virus (RLV), radiation leukemia virus (RAD LV), or a wild type murine leukemia virus (MuLV) which was isolated from a 3MC-induced tumor in a C57BL/6J mouse. Four-wk-old mice were immunized by a single i.p. injection of vaccine. Four wk later, vaccinated mice were challenged with a single intrascapular s.c. injection of 150 μg of 3MC. RLV vaccine reduced the incidence of sarcomas from 75% to 50% in the BALB/cCr mice. RadLV vaccine and MuLV vaccine reduced the incidence of sarcoma from 86% to 33% and 37%, resp, in the C57BL/6Cum mice. The significant reduction in 3MC-induced sarcomas by type C virus supports the idea that the type C RNA viruses are involved in the etiology of chemically induced tumors.

2965 STRAIN DIFFERENCE IN CARCINOGENESIS BY URETHAN ADMINISTRATION TO SUCKLING RATS. (E.) Matsuyama, M. (Aichi Cancer Ctr. Res. Inst., Japan), H. Suzuki, M. Ito, S. Yamada and T. Nagayo. *Gann* 63(2):209-215, 1972.

Urethan was administered to suckling rats in order to disclose its neoplastic potential in various tissues. Male and female Buffalo and Long-Evans strain rats were given five weekly s.c. injections of urethan (1 mg/g body wt) beginning at seven days of age. Untreated rats of both strains served as controls. The experiment was terminated after 130 wk at which time all animals were sacrificed and tumor-bearing tissues were examined histologically. Seventy to 100% of the treated rats of both strains had one or more primary tumors at the time of death. A large strain difference was observed in the susceptibility of various organs to urethan carcinogenesis between Buffalo and Long-Evans strains. Buffalo rats had thymomas, malignant lymphomas, mammary fibroadenomas and liver tumors but no kidney tumors. Long-Evans rats primarily had kidney tumors. Both treated strains each developed three B-cell adenomas of the pancreatic islets. Although a wide range of other tumors were found, none developed at the site of injection.

2966 NITROSAMINE FORMATION *IN VIVO*: INDUCTION OF LUNG ADENOMAS IN SWISS MICE BY CONCURRENT FEEDING OF NITRITE AND METHYLUREA OR ETHYLUREA. (E.) Mirvish, S. S. (U. Nebraska Med. Ctr., Omaha), M. Greenblatt and V. R. C. Kommineni. *J Nat Cancer Inst* 48(5):1311-1315, 1972.

Non-inbred male and female Swiss mice were maintained for 28 wk on a diet containing either 5.36 g methylurea/kg food or 6.36 g ethylurea/kg food. Half of each group also received a solution of sodium nitrite (1.0 g/l drinking water). All animals were maintained an additional 12 wk without treatment and were then sacrificed and examined for lung adenomas and malignant lymphomas. Although tumor incidence was the same as controls in mice fed only methylurea or ethylurea or in mice receiving only sodium nitrite,

mice fed a combination of methylurea or ethylurea and nitrite had a highly significant ($P < 0.001$) increase in lung adenomas. More than two lung adenomas/mouse occurred in 33 of the 57 mice treated with alkylurea plus nitrite, but in only two of 73 mice treated with alkylurea alone. No sex-dependent difference was observed. Malignant lymphoma also occurred with a higher incidence ($P < 0.05$) in alkylurea-plus-nitrite group (10 of 57 mice) than in the untreated controls (10 of 144 mice). The results indicate that the lung adenomas were induced by methylnitrosourea and ethylnitrosourea, formed by *in vivo* nitrosation of the corresponding alkylureas.

- 2967 INFLUENCE OF AGE AND SEX ON HEPATIC LESIONS INDUCED BY CHEMICAL CARCINOGENS: INGESTION OF 3'-METHYL-4-DIMETHYLAMINOAZOBENZENE BY BUFFALO STRAIN RATS. (E.) Reuber, M. D. (Dept. Path., U. Maryland Sch. Med., Baltimore), K. Stromberg and E. L. Glover. *J Nat Cancer Inst* 48(3):675-683, 1972.

Inbred Buffalo strain mice and female rats 5, 8, 12, 24 and 52 wk old were fed a synthetic diet containing 0.06% 3'-methyl-4-dimethylaminoazobenzene (3'-MeDAB) for four-wk periods, followed by one wk on a basal diet, until the carcinogen had been administered for 12 wk. Control rats given the basal diet without 3'-MeDAB. At the end of 24 wk all surviving animals were killed. All animals were autopsied. No control animals developed lesions of the liver or other organs. The younger (five and eight-wk-old) rats developed the highest incidence of cholangiocarcinomas, hepatocellular carcinomas, cirrhosis and liver cholangiofibrosis. The incidence of these lesions was the same for males and females. The younger rats also tended to have more carcinomas per liver and larger carcinomas than did 12, 24 hr 52-wk-old animals. Cholangiocarcinomas tended to metastasize most often in male rats five and eight wk old. Metastases were not observed in females older than eight wk. Metastases of poorly differentiated or undifferentiated cholangiocarcinomas were usually seen in lungs, thymic lymph nodes, omentum, and occasionally on the peritoneal surfaces. No metastases of hepatocellular carcinomas were seen in either sex. Male rats 12, 24 or 52 wk old were more susceptible than females of the same ages ($P < 0.01$) to the development of hepatic lesions.

- 2968 EFFECT OF NEURAMINIDASE ON GROWTH OF A 3-METHYLCHOLANTHRENE-INDUCED FIBROSARCOMA IN NORMAL AND IMMUNOSUPPRESSED SYNGENEIC MICE. (E.) Simons, R. L. (Dept. Surg., U. Minnesota, Minneapolis), A. Rios, P. K. Ray and G. Lundgren. *J Nat Cancer Inst* 47(5):1087-1094, 1971.

Treatment of a weakly immunogenic 3-methylcholanthrene-induced fibrosarcoma (MC-42) with *Vibrio cholerae* neuraminidase (VCN) *in vitro* interfered with growth of the tumor cells in syngeneic C3H/HeJ female mice. Palpable tumors did not appear in some recipients, and

many of the tumors which did appear spontaneously regressed. The effect could be detected at all tumor cell doses and at low concentrations of VCN. The recipients that survived were treated a second time by subsequent inoculations of large numbers of MC-42 cells, but tolerated the growth of immunologically distinct, 3-methylcholanthrene-induced fibrosarcomas (MC-43). The inhibitory effect of VCN treatment on tumor growth was attributed to host inactivation of the enzyme or to inactivation of the enzyme with sialic acid—a negative feedback inhibitor of neuraminidase. VCN-treated tumor cells grew as rapidly as control cells in immunosuppressed recipients. The results are consistent with the hypothesis that removal of the terminal sialic acid residues from the cell surface does not interfere with the intrinsic growth potential of the tumor cells, but that it increases the immunogenicity of tumor-specific transplantation antigens on the cell surface. Increased tumor immunogenicity is probably the result of changes on the cell surface which make the treated cells more susceptible to immunologic processing by the recipient.

- 2969 RELATIVE DNA CONCENTRATION IN MOUSE EPIDERMIS TREATED WITH CARCINOGENS OR CROTON OIL. (E.) Garcia, H. (U. Nebraska Coll. Med., Omaha) and S. Leiva. *Tumori* 57(3):129-132, 1971.

SLJ newborn mice were arranged in four experimental groups. Group 1 was painted on the skin of the back with one drop of 7,12 dimethylbenz(a)anthracene (DMBA) as a 1% solution in mineral oil. Group 2 was painted in the same way with a 5% solution of croton oil in mineral oil. Group 3 was inoculated subcutaneously with 0.5 mg of urethan in distilled water. Group 4 served as the control and was painted on the skin with mineral oil only. Animals were sacrificed after 24 hr and skin biopsies from the treated areas were fixed and stained by the Feulgen reaction method. Relative DNA content of epidermal cells was determined by the optical density of the nuclear stain as measured by histophotometry. Increases in the percentage of nuclei with higher DNA concentrations were observed in all experimental groups. No significant differences between DMBA, urethan and croton oil in relation to early alterations in DNA concentration of basal cells were observed. In the cases of DMBA and croton oil, these increases corresponded to periods of increased thymidine incorporation, as previously reported in the literature. With urethan, however, DNA concentration remained high after 24 hr. even though thymidine incorporation had decreased by this time. It was concluded that the modifications in DNA content of epidermal cells of mice induced by croton oil and carcinogens were probably incidental phenomena, not strictly related to the process of carcinogenesis.

- 2970 7,12-DIMETHYLBENZ(a)ANTHRACENE-INDUCED NEONATAL CARCINOGENESIS AND ANAMNESTIC IMMUNE RESPONSE IN THE SWISS MOUSE. (It.) Baroni, C. D. (Inst. Path. Anat. Hist., U. Rome, Italy), R.

Scelsi, P. C. Mingazzini and S. Uccini. *Boll Ist Sieroter Milan* 50(4):303-305, 1971.

Swiss mice were injected with 7,12-dimethylbenz(a)-anthracene (DMBA; 100 µg s.c.) in olive oil 16-18 hr after birth and were sacrificed at 30-200 days of age. Controls and DMBA-treated mice received two i.p. injections of sheep red-blood cells: one 20 days before sacrifice and the other, 48 hr before. The total number of nucleated spleen cells was counted, and the number of hemolysis plaques was counted after spleen cells had been incubated with rabbit anti-gamma-globulin serum; the latter test is a measure of 7S or IgG hemolysin. Although the total number of spleen cells remained almost constant in both control and treated mice during this experiment, the number of plaque-forming cells was consistently lower in DMBA-treated mice than in controls, even before tumors developed. These findings indicate that DMBA has an immunosuppressive effect on secondary or anamnestic immune response. It is suggested that when DMBA is injected at birth, it probably acts on the immune system via bone marrow precursors.

2971 REACTION OF ALKYLATING MUTAGENS AND CARCINOGENS WITH NUCLEIC ACIDS: N-3 OF GUANINE AS A SITE OF ALKYLATION BY N-METHYL-N-NITROSOUREA AND DIMETHYL SULPHATE. (E.) Lawley, P. D. (Chester Beatty Res. Inst., London, England), D. J. Orr and S. A. Shah. *Chem-Biol Interactions* 4(6):431-434, 1971/72.

Small amounts of N-3 alkylation of guanine residues have been detected *in vitro* in nucleic acids or poly(G) treated at neutral pH with agents of both S_N2 and S_N1 types (represented by dimethyl sulphate (DMS) or N-methyl-N-nitrosourea (MN), resp.). The yield of 3-methylguanine from treated salmon sperm DNA, identified by chromatography, spectrometry, or both, was 1.1 mmole/mole DNA-P for MN and 0.3 mmole/mole DNA-P for DMS. N-7 methylation of DNA guanine was also seen in DMS- and MN-treated bacteriophage µ2 RNA, rabbit reticulocyte rRNA and poly(G). The only tautomeric structure of 7-methylguanine nucleoside which would be likely to permit Watson-Crick base-pairing was the form with an imino group at the 2-position, and this form would tend to promote mispairing with thymine. Such a mispairing mechanism might possibly explain the relatively weak mutagenic activity of S_N2 alkylating agents.

2972 SYNTHESIS AND ONCOGENICITY OF 3-HYDROXYURIC ACID. (E.) Lee, T.-C. (Sloan-Kettering Inst., New York, N. Y.), G. Stöhrer, M. N. Teller, A. Myles and G. B. Brown. *Biochemistry* 10(24):4463-4466, 1971.

3-Hydroxyuric acid was synthesized by a method which involves cyclization in base of the imidazolone ring of uric acid. An initial oncogenesis assay

with five rats administered s.c., led to one tumor in five rats. A repeat test with 21 rats resulted in a 19% incidence at a dose level of 1.0 mg, which is to be compared with a 100% incidence at 0.5 mg doses and 30% at 0.1 mg doses, on the same dosage schedule, with 3-hydroxyxanthine. Controls with the vehicle and with uric acid, as well as with xanthine were all negative. *In vitro*, xanthine reduces a small portion of 3-hydroxyuric acid to 3-hydroxyxanthine. The results suggest that the compounds oncogenicity can be attributed to the reduction *in vivo* of a portion of it to 3-hydroxyxanthine.

2973 MORPHOLOGIC FEATURES OF MAMMARY CARCINOMAS IN WOMEN TAKING HORMONAL CONTRACEPTIVES.

(E.) Gould, V. E. (U. Washington Sch. Med., Seattle), M. Wolff and N. K. Mottet. *Amer J Clin Path* 57(2): 139-143, 1972.

Carcinomas of the breast in three women taking hormonal contraceptives had both lobular and ductal components, secretory activity, and conspicuous mucopolysaccharides in the stroma of the involved lobules and around the neoplastic ducts. The lesions were pleomorphic and diffuse and contained abundant lymphocytic infiltration. Although these observations suggest very variable target organ responsiveness to hormonal stimulation, the problem requiring investigation is not just whether a distinctive pattern of breast carcinoma is associated with hormonal contraceptive intake, but rather whether it might, in some instances, alter the evolution of the disease.

2974 CARCINOGENIC EFFECT OF N,N'-DIMETHYLNITROSOUREA ON SYRIAN HAMSTERS. (E.) Hiraki, S. (Dept. Path., Okayama U. Med. Sch., Japan). *Cann* 62(4):321-323 (and Plate LXIII), 1971.

Thirty-four Syrian hamsters, 8-10 wk old, were given s.c. administrations of N,N'-dimethylnitrosourea (DMN) at weekly intervals in the intrascapular region in a dose of 40 mg/kg body weight. Control hamsters were injected s.c. with saline solution. All the treated hamsters were found dead or killed between 17 and 31 wk, and the average lifespan was 24 wk. Twenty-three (68%) of all the treated hamsters had well-differentiated squamous cell carcinoma of the forestomach which showed no metastasis or infiltration into other organs. After 18 injections, 11 (79%) of all the treated females developed three or four s.c. tumors derived from the mammary glands. The histological pattern of the tumors showed adenocarcinoma or adenoacanthoma. Twelve (86%) of all the treated females had tumor in the uterine cervix (adenoacanthomas). Four males and two females (18%) developed tumors of the pancreas (adenocarcinoma). In addition, cholangiocarcinoma of the liver was found in eight (24%) and anaplastic sarcoma situated at the dorsal subcutis in two (6%). The instability of DMN in aqueous solutions and the induction of various tumors at a site remote from the injection

site suggest that DMH is rapidly absorbed from s.c. tissue into the systemic circulation without loss of its carcinogenic activity and its subsequent derivative may induce these malignant tumors.

- 2975 INHIBITION OF MAMMARY TUMORIGENESIS BY ERGOT ALKALOIDS AND PROMOTION OF MAMMARY TUMORIGENESIS BY PITUITARY ISOGRAFTS IN ADRENO-OVARECTOMIZED MICE. (E.) Yanai, R. (Nat). Cancer Ctr. Res. Inst., Tokyo, Japan) and H. Nagasawa. *J Nat Cancer Inst* 48(3):715-719, 1972.

The effect of ergocornine or 2-bromo- α -ergocryptine (CB-154) in intact C3H/He virgin mice and the effect of pituitary isografts in adreno-ovariectomized mice on spontaneous tumor incidence were investigated to clarify the importance of prolactin on mammary tumorigenesis. Each alkaloid was mixed with cholesterol, 1:4, and 50 mg was pelleted and implanted s.c.. Control mice received cholesterol implants. At the end of eight months, mammary tumor incidence was 23.5 and 16.7% in mice implanted with ergocornine and CB-154, resp., whereas the incidence in control mice was 73.7%. It was concluded that mammary tumor incidence was significantly inhibited by these ergot alkaloids through their suppression of pituitary prolactin secretion. Mammary tumor incidence was 51.3% at the end of eight months after three pituitaries each were grafted in adreno-ovariectomized mice, while no tumors appeared in the adreno-ovariectomized controls. This indicated that prolactin secreted continuously by the grafted pituitaries promoted the development of spontaneous mammary tumors in the apparent absence of adrenal and ovarian hormones. These results demonstrated that prolactin is a primary hormonal factor in spontaneous mammary tumorigenesis in mice.

- 2976 ACUTE LEUKEMIA DUE TO CHRONIC EXPOSURE TO BENZENE. (E.) Aksoy, M. (Istanbul Med. Sch., Turkey), K. Dincol, S. Erdem and G. Dincol. *Amer J Med* 52(2):160-165, 1972.

Four cases of acute leukemia in shoemakers chronically exposed to benzene-containing adhesives are presented. In each case the patient's employment record indicated heavy exposure over long periods of time to benzene vapors. In two of the patients aplastic anemia had been previously diagnosed, whereas in the other two, leukemia developed without a prior episode of anemia. Hematological data and course of treatment are presented for each patient. A rising incidence of leukemia among shoemakers in Istanbul is related directly to benzene compounds commonly used in adhesives employed in the manufacture of shoes.

- 2977 IMMUNE SUPPRESSION INDUCED BY 4-NITROQUINOLINE 1-OXIDE AND ITS DERIVATIVES. (E.) Nakashima, S. (Drug Res. Inst., Toyama U., Japan) and S. Ono. *Germ* 63(1):111-117, 1972.

The immunosuppressive response elicited in mice by 4-nitroquinoline 1-oxide (4-NQO) and 4-hydroxyaminoquinoline (4-HAQO) was studied. Forty-eight female ddY mice weighing 20-22 g were antigenically stimulated by i.p. injections of 0.25 mg of bacterial α -amylase. Sera of these animals were then analyzed to establish antibody titer baselines. Starting on the day of immunization, six groups of eight mice each were given injections of 4-HAQO or 4-NQO in different doses and at different intervals. Two other groups were given injections of the noncarcinogenic 4-aminoquinoline 1-oxide (4-AQO). A control group of saline-treated mice was established. Changes in the antibody titers of all animals were followed during the entire course of treatment. The results indicate that the suppressive activity of 4-NQO is dose-dependent. Since the carcinogenic 4-NQO and 4-HAQO were immunosuppressive and noncarcinogenic 4-AQO was not, the suppressive action of the first two agents may bear some relation to their carcinogenicity.

- 2978 IN VIVO CONVERSION OF PHENMETRAZINE INTO ITS N-NITROSO DERIVATIVE. (E.) Greenblatt, M. (U. Nebraska Med. Ctr., Omaha), V. Komineni, E. Conrad, L. Wallcave and W. Lijinsky. *Nature New Biol* 236(62):25-26, 1972.

The nitrosation of phenmetrazine (3-methyl-2-phenylmorpholine) and phendimetrazine (3,4-dimethyl-2-phenylmorpholine), two drugs commonly taken for appetite control, was studied. Rabbits received intragastric injections of aqueous solutions of phenmetrazine (177 mg) or phendimetrazine containing sodium nitrite, and the N-nitroso derivative, nitrosophenmetrazine (NPM), was identified by gas chromatography. Whereas phenmetrazine was converted to NPM (13 to 18% of theoretical after five hr), no NPM was found in gastric juice from rabbits injected with phenmetrazine or nitrite alone. Gastric concentrations of NPM and nitrite were highest one hr after injection (0.64 mg NPM and 0.12 mg nitrite per ml) and declined rapidly thereafter. The decline in NPM concentration was probably due in part to absorption from the stomach. Conversion of phenmetrazine to NPM increased with increasing nitrite concentration. Insignificant amounts of NPM were produced when nitrate was substituted for nitrite. Similar experiments with rats showed as efficient nitrosation of phenmetrazine. Although it is not known whether NPM is carcinogenic, related nitroso derivatives are carcinogenic in rats, and therefore ingestion of phenmetrazine when food containing nitrite is also present in the stomach may constitute a hazard.

- 2979 EVIDENCE FOR DNA REPAIR SYNTHESIS AND TURNOVER IN RAT LIVER FOLLOWING INGESTION OF 3'-METHYL-4-DIMETHYLAMINOAZOBENZENE. (E.) Goodman, J. I. (McArdle Lab. Cancer Res., U. Wisconsin, Madison) and V. R. Potter. *Cancer Res* 32(4):766-775, 1972.

Hepatic DNA of immature (50 g, 25-day-old) male Sprague-Dawley rats was prelabeled by i.p. injection of ^{14}C -thymidine. When the animals reached 200 g (53 days old), they were placed on a diet containing 0.05% (w/w) of the hepatic carcinogen, 3'-methyl-4-dimethyl-aminoazobenzene (3'-MeDAB). Groups of animals were then sacrificed at weekly intervals over a period of five weeks. Two hr prior to sacrifice, each animal received a single i.p. injection of ^3H -thymidine for the labeling of newly synthesized DNA. Radioactivity was determined in total liver homogenates (hepatocyte plus "stromal" cells), in DNA from purified hepatocyte homogenates, and in purified hepatocyte nuclei and "stromal" nuclei. Over the course of the experiment, there was a marked and progressive loss (up to 80%) of DNA ($t_{1/2} = 13$ days) from the livers of 3'-MeDAB-treated animals, as determined by the loss of ^{14}C -labeled DNA. This was accompanied by an increase in the amount of the ^3H -labeled DNA. Total hepatic cell DNA remained constant, indicating that 3'-MeDAB initially caused a profound increase in turnover of hepatic cell DNA. The effect of 3'-MeDAB was specific for hepatic cell DNA, since no loss of prelabeled renal cell DNA was observed. So that a higher percentage of prelabeled hepatocyte DNA could be obtained, rats were labeled with ^3H -thymidine after partial hepatectomy. Four weeks later, the animals were placed on the 3'-MeDAB diet; loss of prelabeled DNA was again studied, and the results agreed with those from the ^{14}C -prelabeled rats. The degree of necrosis seen in histological sections was insufficient to account for the observed loss of DNA. Studies of DNA sedimentation in alkaline sucrose gradients indicated that repair of hepatic DNA was an early consequence of 3'-MeDAB infection and accounted for some of the increased DNA turnover. Since gene transcription might have been inhibited or altered during DNA repair and since unrepaired DNA segments could result in misreading, it was possible that 3'-MeDAB-induced repair was one of the mechanisms underlying the change in gene expression observed in precancerous livers.

980 CHANGES IN RIBONUCLEIC ACID DEGRADING ENZYMES IN EHRlich ASCITES CELLS DURING GROWTH AND AFTER ACTINOMYCIN D TREATMENT. (E.) Rowth on Tigerstrom, R. G. (U. Alberta Cancer Res. Unit, Edmonton, Canada). *Can J Biochem* 50(3):244-252, 1972.

Ehrlich ascites cells were treated with actinomycin (act D) (5 $\mu\text{g}/\text{ml}$, 15 min) and injected i.p. into a/ICR Swiss mice. Control animals received injections of saline-treated ascites cells. After even days spectrophotometry of the act D-treated cells showed increases in alkaline RNase II, acid RNase I and phosphodiesterase II activities of 7.2-, 10- and 2.5-fold, resp., as compared with controls. RNase inhibitor activity was significantly lower than in controls. RNase I, phosphodiesterase I and acid phosphatase activities were unchanged. Smaller increases in the same enzyme activities, but no change in RNase inhibitor activity, were observed

when untreated cells were collected after four days instead of after seven days of growth. Net synthesis of protein and RNA, determined by the rate of incorporation of ^{14}C -leucine and ^{14}C -guanine into acid-insoluble material, was slightly faster when control cells were collected after four instead of seven days. Protein synthesis in act D-treated cells was the same as in controls at seven days. Although initial rates of RNA synthesis were the same in control and act D-treated seven-day cells, treated cells showed a rapidly decelerating rate after 30 min, whereas incorporation into controls was linear for two hr. One possible reason for this was the higher RNase and phosphodiesterase activities in act D-treated cells. However, little or no difference between treated and control cells was seen in the degradation of nuclear RNA after 30 min. RNase levels in act D-treated cells were similar at seven and nine days after transplantation and RNase inhibitor levels were increased from a low level at seven days to high levels at nine days. However, RNA and protein synthesis was similar at seven and nine days. Therefore it was concluded that RNase inhibitor had little influence on the rate of protein synthesis, net RNA synthesis and possibly on the rate of nuclear RNA degradation. It was also concluded that different levels of RNase activities, as measured by *in vitro* assays, do not affect the rate of protein synthesis.

2981 REPLICATION OF LOW-LEVEL CARCINOGENIC ACTIVITY BIOASSAYS. (E.) Van Duuren, B. L. (New York U. Med. Ctr., N.Y.), C. Katz, M. B. Shimkin, D. Swern and R. Weider. *Cancer Res* 32(4):880-881, 1972.

Carcinogenic activity of five compounds (stearic acid, methyl stearate, and γ -stearolactone, which were not expected to be carcinogenic, and p-nitroperbenzoic acid and glycidyl stearate which were expected to be carcinogenic), was determined independently in two laboratories using the same batches of chemicals and vehicle. ICR/Ha Swiss Millerton female mice or CFW (Swiss Webster) female mice were given s.c. injections of chemical once weekly for 26 wk (1.3 to 130 mg, total dose) and sarcoma induction was determined. The results between the two laboratories in terms of s.c. sarcoma induction were very similar. Stearic acid failed to induce any sarcomas at the injection sites; the other four substances induced sarcomas in less than 10% of the animals. Data on tumor induction in various organs did not contribute further evidence of carcinogenic activity of the compounds. Activity of the two compounds, methyl stearate and γ -stearolactone, which were not expected to be carcinogenic was not due to "solid-state" carcinogenesis, since they were lipid-soluble.

2982 LACTATE DEHYDROGENASE ISOZYME IN MOUSE LUNG CANCER PRODUCED BY 4-NITROQUINOLINE 1-OXIDE. (E.) Yamane, Y. (Fac. Pharmaceutical Sci., Chiba U., Japan), K. Sakai and Y. Amemiya. *Gann* 63(2):153-159, 1972.

Female dd-yf strain mice received intrascapular s.c. injections of a lecithin suspension of 4-nitroquinoline 1-oxide (4-NQO) weekly for six weeks (total dose: 1.50 mg/mouse). At different times after the end of the injection period, lung tissue was removed and homogenates were tested for total LDH activity by spectrophotometric measurement of the oxidation of NADH. LDH isozymes were separated by agar gel electrophoresis. All animals developed lung tumors within 3.5 months. Total LDH activity did not differ between control and experimental groups up to 3.5 months even though small tumors were present. After five months, however, total LDH activity had increased in the carcinogen-treated group to a value 1.7 times that of control. This increase was presumably due to an increase in the amount of tumor tissue relative to normal lung tissue. LDH activity in tumorous portions of the lung was 2.5 to 3.5 times that of normal control lung tissue and up to 50% higher than that of normal embryonic mouse lung. After six months, tumor-bearing mouse lung showed a 40% decrease in the activity of LDH fractions I and II and a 20% increase in the activity of fractions IV and V compared with control lung. In tumor tissue, fraction I was totally absent, fraction II was decreased by 70%, and fractions IV and V were increased by 25% and 10%, resp. This pattern was identical to that of embryonic lung tissue. These results indicated that an increase in M-type LDH activity had occurred in 4-NQO-induced lung cancer, which was similar to the pattern observed in embryonic lung tissue.

- 2983 CHEMICAL BINDING OF CARCINOGENIC 4-NITROQUINOLINE 1-OXIDE DERIVATIVES WITH DNA *IN VIVO* AND *IN VITRO*. (E.) Kawazoe, Y. (Natl. Cancer Ctr. Res. Inst., Tokyo, Japan), G.-F. Huang, M. Araki and C. Koga. *Gann* 63(2):161-166, 1972.

Thirteen ^3H -labeled derivatives of 4-nitroquinoline 1-oxide (4-NQO) were studied for their ability to bind DNA. Ehrlich ascites were incubated *in vitro* for two hr with each chemical (10^{-4} M), the cellular DNA was then purified, and the radioactivity was determined in a scintillation counter. In other experiments, purified calf thymus DNA was incubated for 48 hr with labeled chemical (5×10^{-4} M) and DNA-bound radioactivity was determined. In both systems, 4-NQO and the two derivatives, 4-hydroxyaminoquinoline 1-oxide (4-HAQO) and diacetyl-4-hydroxyaminoquinoline 1-oxide (Ac₂-4-HAQO), showed the most potent binding ability, in that order. Since these three chemicals are the most carcinogenic of the derivatives and since the least carcinogenic derivatives bound to DNA with much less affinity, it was concluded that carcinogenic ability was associated with the DNA-binding ability of these compounds.

- 2984 EPOXIDES OF CARCINOGENIC POLYCYCLIC HYDROCARBONS ARE FRAMESHIFT MUTAGENS. (E.) Ames, B. N. (Dept. Biochem., U. California, Berkeley), P. Sims and P. L. Grover. *Science* 176(4030):47-49, 1972.

A set of tester strains (TA 1538, TA 1537, and TA 1534) developed in *Salmonella typhimurium* have been designed for detecting frameshift mutagens of varying specificity. The 2-region epoxides of benz[a]anthracene and 7-methylbenz[a]anthracene were found to be the only compounds tested to cause mutations in these strains; parent hydrocarbons, K-region diols and phenols and some other epoxides were inactive as mutagens in these tests. Some of the compounds were active against another tester strain, TA 1535, which detects base-substitution mutagens. Benz[a]anthracene 1,6-oxide and 7-methylbenz[a]anthracene 3,4-oxide gave positive results in a forward mutation test which detects both base substitutions and frameshift mutations. A new tester strain, TA 1537, was constructed and found to be excellent for detecting frameshift mutagenesis effected by dibenz[a,h]anthracene 1,6-oxide. Indirect evidence showing that the epoxides were reacting with bacterial DNA, as well as intercalating, was obtained by comparing their mutagenic effect on strains with and without excision repair. It is postulated that polycyclic hydrocarbons may be carcinogenic because of the mutagenicity of epoxide intermediates formed during metabolism and that the mechanism of action may involve intercalation followed by covalent reaction.

- 2985 *IN VITRO* MALIGNANT TRANSFORMATION OF CELLS DERIVED FROM PULMONARY AND WHOLE EMBRYONIC TISSUES OF STRAIN A MICE BY 4-NITROQUINOLINE 1-OXIDE. (E.) Toyoshima, K. (Nara Med. U., Japan), H. Tsuji and Y. Tsubura. *J Nara Med Ass* 22(2,3):162-174, 1971.

Cells were derived from either pulmonary or whole tissues from embryos of strain A mice. These cells consisted of either polyhedral epithelial cells surrounded by spindle-shaped fibroblasts, or of fibroblast cells alone. Once tissue cultures established, they were exposed to 4-nitroquinoline 1-oxide at different concentrations and for various lengths of time. Exposure to the chemical at concentrations of 3.9×10^{-8} M had a cytotoxic effect to which the epithelial cells were more susceptible than the fibroblast cells. At lower concentrations of 2.6×10^{-7} M, 4-nitroquinoline 1-oxide caused malignant transformations of both cell types, as evidenced by a decrease in doubling time, a loss of contact inhibition, an increase in saturation density, and a positive shift to tetraploidy in chromosomal number. Transformation was confirmed by inoculation of the chemically treated cells into strain A mice; both transformed strains produced tumors, histologically identified as fibrosarcomas, in the recipients.

- 2986 CARCINOGENIC COMPOUNDS ON EDIBLE MEAT IN NEW ZEALAND. (E.) Dacre, J. C. (Med. Res. Council New Zealand, Dunedin). *N Z Med J* 73(465):74-77, 1971.

A survey was made in New Zealand of the marking-dyes

applied to meats that are destined for human consumption. Samples of the colors were obtained from the dye manufacturer and from the meat-packing plants; in addition, the colors were extracted from meats purchased in supermarkets. Following thin layer chromatographic techniques and absorption spectroscopy, the dyes were classified as to toxicity. Namely, tartrazine and sunset yellow FCF were acceptable for use in foods; benzyl violet 4B had a potential for inducing harmful effects; there was insufficient data to form a conclusion concerning violet 5BN and methyl violet; and magenta and auramine were found to be harmful. Interestingly, since the initiation of the use of these dyes, bladder cancer has increased in New Zealand, particularly in the male population. The use of such food marking-dyes may play a role in this increase.

- 2987 URINARY CYTOLOGY IN WORKERS EXPOSED TO CARCINOGENIC AROMATIC AMINES: A SIX-YEAR STUDY. (E.) Forni, A. (U. Milan, Sch. Med., Italy), G. Ghetti and G. Armeli. *Acta Cytol* 16(2):142-145, 1972.

A follow-up cytologic study of urinary sediment by the Papanicolaou method was carried out in workers of the dyestuff industry with past or present exposure to carcinogenic aromatic amines. Between September 1964 and December 1970, 858 workers received one or more cytologic examinations for a total of 8,249; 304 workers are presently lost to follow-up. During this time 16 workers developed bladder tumors (ten papillomas and six carcinomas), and one developed multiple papillary carcinoma of the left ureter. Fourteen of these tumors were diagnosed by cytology; one case of papilloma had persistent negative cytology, also on reexamination; two subjects with papilloma were not under cytologic control prior to diagnosis. Moreover 13 diagnoses of recurrence were made in nine workers and confirmed, while six recurrences were suspected at cytology, but so far were not confirmed. The time elapsed between cytologic and cystoscopic or histologic diagnosis of bladder tumors was from less than 1 to 67 months for the new cases, and from less than 1 to 32 months for the recurrences. Some subjects with intermittent suspicious cytology had cystoscopic findings negative for tumor, with inflammatory or congestive changes; of these workers, some are lost to follow-up, while the remainder are still followed by periodical cytologic examination.

- 2988 SOME PRELIMINARY OBSERVATIONS ON THE BINDING OF URETHAN TO DNA OF SEVERAL TISSUES OF MICE AND RATS. (E.) Bhide, S. V. (Cancer Res. Inst., Tata Memorial Ctr., Bombay, India), E. Premkumar, M. A. Siddiqui and P. M. Bhargava. *Indian J Cancer* 8(3):172-175, 1971.

Three- to four wk-old male Swiss mice and three- to four-month-old male inbred albino rats were given

i.p. injections of isotopically labeled urethan at different specific activities. Animals were sacrificed at intervals up to 48 hr and DNA was purified from lung, liver and kidney homogenates. Although urethan was bound to DNA from all three tissues, maximal radioactivity was associated with lung DNA. Maximal binding of urethan to lung and liver DNA occurred earlier (12 hr) than maximal binding to kidney DNA (24 hr). Specific activity of urethan-bound DNA was higher in the mouse than in the rat. The extent of binding was dependent on the urethan dose, with significant increases in the range of 0.5-1.0 mg/g body weight, concentrations which had previously been shown to cause tumor induction. Stability of binding under various conditions indicated that urethan or a metabolite was covalently bound to DNA.

- 2989 CYTOTOXIC EFFECTS OF D-GLUCOSAMINE ON THE ULTRASTRUCTURES OF NORMAL AND NEOPLASTIC TISSUES *IN VIVO*. (E.) Molnar, Z. (Dept. Path. U. Chicago, Ill.) and J. G. Bekesi. *Cancer Res* 32(4):756-765, 1972.

The effects of continuous D-glucosamine infusion (350 mg/kg/hr) on the fine structure of Walker carcinoma and normal liver and kidney of adult male Sprague-Dawley rats were studied *in vivo*. Infusion for 18 hr caused a slight dilation of the cisternae of the endoplasmic reticulum (ER) and Golgi sacs of tumor and liver parenchymal cells. The epithelial cells of renal tubules contained lamellar structures within numerous autophagic vacuoles. Infusion for 40 hr produced conspicuous degenerative changes in the nuclei and nucleoli of tumor cells. The nuclear matrix showed a much-decreased electron-density and contained clumped interchromatin granules. Nucleoli were rounded up and the strands of the nucleolonema had coalesced. Conspicuous small aggregates of high-contrast material (probably chromatin) had formed, predominantly in the electron-lucent areas of the nucleolus. Cytoplasmic changes in tumor cells were less pronounced than the nuclear ones. Liver parenchymal cells showed almost complete fragmentation of the long profiles of the rough ER into small vesicles. Autophagic vacuoles were frequently seen. Only single rows of cisternae remained surrounding the mitochondria. The cytoplasm of the lining epithelium of the renal proximal tubules was highly vacuolated. Necrosis was never observed in renal or hepatic tissue. However, tumor tissue of rats sacrificed five days after a 40-hr infusion of D-glucosamine was completely necrotic. Associated with this was an almost complete recovery of renal and hepatic cell ultrastructure.

- 2990 KINETIC, IMMUNOCHEMICAL, AND PHYSICAL STUDIES ON PURIFIED RAT LIVER ADENOSINE 5' PHOSPHATE DEAMINASE AFTER INDUCTION WITH 3'-METHYL-4-DIMETHYLAMINOAZOBENZENE OR THIOACETAMIDE. (E.) Smith, L. D. (Samuel Roberts Nobel Fdn., Inc., Ard-

more, Okla.) and D. E. Fizer. *Cancer Res* 31(19):1341-1347, 1971.

After induction with hepatocarcinogens and partial purification, kinetic, immunochromatographic, and physical properties of rat liver AMP deaminase were studied. The hepatic enzyme was induced by intraperitoneal injections of thioacetamide or 3'-methyl-4-di-methylaminoazobenzene. Enzymes were purified by lithium sulfate precipitation, heat treatment, diethylaminoethyl cellulose chromatography, and gel filtration. The activity of both the induced enzyme and the normal enzyme was modulated by ATP, GTP, and alkali metal ions. Induction did not alter GTP inhibition of ATP activation. Data were obtained suggesting that citrate ion altered substrate affinity and inhibited ATP-GTP modulation of enzyme activity. Studies with antibody to rat liver AMP deaminase developed in rabbits indicated that the induced enzyme had essentially identical titration equivalence with the noninduced enzyme in both the crude and partially purified states. Lability of the induced enzyme cohort in the 105,000 X g supernatant fraction to heating at 55° was lost when it was partially purified.

- 2991 THE EFFECTS OF TWO ISOMERIC BENZOFLAVONES ON ARYL HYDROCARBON HYDROXYLASE AND THE TOXICITY AND CARCINOGENICITY OF POLYCYCLIC HYDROCARBONS. (E.) Diamond, L. (Wistar Inst. Anatomy Biol., Philadelphia, Pa.), R. McFall, J. Miller and H. V. Gelboin. *Cancer Res* 32(4):731-736, 1972.

The effects of two isomeric benzoflavones (BF), 5,6-BF and 7,8-BF, were studied on aryl hydrocarbon hydroxylase (AHH) activity in hamster embryo (HE) cell cultures, on 7,12-dimethylbenz(a)anthracene (DMBA)-induced adrenal necrosis and lung tumorigenesis in female Sprague-Dawley rats and A/HeJ mice *in vivo*, and on the metabolism and cytotoxicity of carcinogenic hydrocarbons in HE cells. At concentrations ten to 20 times higher than that of the hydrocarbons, 7,8-BF almost completely inhibited the metabolism of isotopically labeled BF and DMBA to water-soluble derivatives in HE cultures. A 5,6-BF concentration 100 times that of the hydrocarbons was required to produce the same degree of metabolism. 5,6-BF doubled AHH activity in HE cells, as measured by fluoromicrophotometry. 7,8-BF inhibited basal AHH activity, as well as benz(a)anthracene-induced AHH. 7,8-BF at a concentration equal to (0.1 µg/ml), or greater than, that of the hydrocarbon protected HE cells against cytotoxicity induced by oral administration of DMBA, BP and 3-methylcholanthrene; 5,6-BF gave slight protection at high concentrations (2 µg/ml). When administered by i.p. injection 48 hr before the hydrocarbon, 7,8-BF was one-tenth as effective as 5,6-BF in protecting rats against DMBA-induced adrenal necrosis and was also a less effective inducer of hepatic AHH. Mice fed a diet containing 5,6-BF or 7,8-BF for two weeks showed induction of AHH activity in liver, lung and small intestine, but not kidney. Oral administration of either 5,6-BF or 7,8-BF prior to administration of DMBA

protected mice against pulmonary adenoma formation, with 5,6-BF being the more potent inhibitor.

- 2992 ADENINE PHOSPHORIBOSYL TRANSFERASE ACTIVITY OF MOUSE ASCITES TUMOR AND DERIVED TUMORIGENIC AND NONTUMORIGENIC TISSUE MATERIALS. (E.) Blair, D. W. E. (Dept. Cancer Biol., U. Louisville, Louisville, Kentucky), L. J. Bricker, M. Deane, W. D. Hunter and L. C. Morgan. *Cancer Res* 32(3):763-770, 1972.

Adenine phosphoribosyl transferase was tested as a possible "marker" enzyme for tumorigenicity of cultured mouse ascites tumor cells. Enzyme-specific activities were determined by a radioisotopic method for cell-free extracts of four tumors: Ehrlich and Ehrlich-lettinger carcinomas, 60MHz lymphoma and T43 adenocarcinoma, and for their derived tumorigenic and nontumorigenic monolayer cultures. Enzyme activity was not correlated with the tumorigenicity of the cells. Whereas the activities were similar and relatively high (1.2 to 2 units/mg protein/hr/mg protein) for the four types of tumor cells obtained directly from mice, those for both tumorigenic and nontumorigenic cultured cells were 33-75% lower. The lower enzyme activities of cultured cells occurred by the fifth passage after culture initiation; they were not attributable to differences in pH optima or optimal concentrations of Mg^{+2} , adenine, or 5-phosphoribosyl-α-1-pyrophosphate. The decreased enzyme activities were not due to the presence of an inhibitor, as extracts from cultured cells did not inhibit the activities of extracts from freshly harvested ascites tumor cells. Little or no loss of activity resulted from storage of extracts at -20 C for 33 days. It is concluded that the lowered enzyme activity of cultured cells was apparently an adaptation to growth *in vitro*.

- 2993 INFLUENCE OF INSULIN DEPRIVATION ON GROWTH OF THE 7,12-DIMETHYLBENZ(a)ANTHRACENE-INDUCED MAMMARY CARCINOMA IN RATS SUBJECTED TO ALLOXAN DIABETES AND FOOD RESTRICTION. (E.) Heuson, J.-C. (Bordet Inst., Free U. Brussels, Belgium) and N. Legros. *Cancer Res* 32(2):226-232, 1972.

Mammary tumors were induced in random-bred, female Sprague-Dawley rats by DMBA feeding. In experiment 1, 20 rats were randomized into two groups of ten, three wk after DMBA feeding. One group served as control; alloxan diabetes was induced in the other. In experiment 2, 90 rats were randomized into two groups of 36 and 54 resp., four wk after DMBA feeding. The first group served as control; alloxan diabetes was induced in the other. Each group was observed for 12 wk. None of the surviving diabetic rats developed mammary tumors, whereas a majority of the controls developed one or several tumors. In experiment 3, 37 tumor-bearing rats were subjected to alloxan diabetes 21 wk after DMBA administration. Fifteen became diabetic and 12 survived at the end of the six wk observation period. There was an average weight loss of 56 g (19% of the ini-

ial weight of 299 g). In these rats, 51 out of 56 tumors initially present (90%) decreased rapidly in size; five continued to grow. Tumor regression in the diabetic rats did not seem to occur as a result of a direct effect of alloxan on tumor tissue. In experiment 4, administration of estradiol benzoate failed to prevent the tumor regression produced by alloxan diabetes. In experiment 5, it was found that food restriction resulted in a rapid tumor regression which was partially counteracted by estradiol benzoate. Tumors regressing as a result of alloxan diabetes, those progressing (about 10%) in spite of diabetes, and those that progressed under the stimulating effect of estradiol benzoate in rats subjected to food restriction were investigated with respect to their insulin dependence in organ culture. It was observed that the tumors regressing in alloxan-diabetic rats were, by and large, markedly insulin dependent *in vitro*, whereas those growing despite diabetes were little- or noninsulin dependent. Eventually, most tumors that are stimulated to grow by estradiol benzoate in food-restricted rats proved very insulin dependent *in vitro*. These observations suggest that the tumors that are insulin dependent in organ culture similarly have a stringent requirement for insulin to grow *in vivo* and that they regress after induction of alloxan diabetes as a consequence of insulin deprivation.

- 2994 SOME PROPERTIES OF POLYADENYLIC ACID AND DNA AFTER TREATMENT WITH THE CARCINOGEN N-ACETOXY-2-ACETYLAMINOFLUORENE. (E.) Michelson, L. M. (Inst. Biol. Phys.-Chim., Paris, France), A. Kapuler and F. Pochon. *Biochim Biophys Acta* 52(4):441-448, 1972.

Chemical, photochemical and physical properties of the homopolymer, poly(A-AAF), were studied. Poly(A-AAF) was formed in a reaction between poly(A) and N-acetoxy-2-acetylaminofluorene (AAAF) at 38°C in the dark, with more than 95% of the adenosine residues being modified. Poly(A-AAF) formed stoichiometric complexes with poly(U) and poly(I), but formation of a double helical "acid form" characteristic of poly(A) could not be observed by UV absorption spectroscopy down to pH 2 in 0.05 to 0.5 M NaCl. Optical rotary dispersion spectra of poly(A-AAF) and its complexes with poly(U) and poly(I) showed no striking differences from those of poly(A) and its complexes, suggesting the same structural characteristics were present in both cases. Irradiation of poly(A-AAF) at 310 nm generated a second polymer, poly(A-AAF)(hv), which was fluorescent at room temperature. Long-wavelength (320 nm) irradiation of DNA-AAF also produced a modified DNA which was strongly fluorescent at room temperature in aqueous buffer. The UV absorption-temperature profiles of DNA-AAF indicated a considerable increase in cross-linking after irradiation. Thermal denaturation and enzymatic degradation of DNA-AAF caused a red shift in the emission spectra, compared with native DNA, suggesting that the fluorescent residues were not free and exterior to the DNA double-strand, as with poly(A-AAF), but

were included to a large extent in the secondary structure. These results suggest that cross-linking of DNA strands (presumably increased by the action of free radicals), and possibly the light sensitivity of AAAF, might play a role in the biological action of the hydrocarbon.

- 2995 THE EFFECT OF TRANSPLENTAL ADMINISTRATION OF DDT ON ORGAN CULTURES OF FOETAL MOUSE LUNG TISSUE. (E.) Shabad, L. M. (Acad. Med. Sci. USSR, Moscow), T. S. Kolesnichenko and T. V. Nikonova. *Int J Cancer* 9(2):365-373, 1972.

The possible carcinogenic effect of the pesticide, DDT, was evaluated by testing the effect of transplacental administration of DDT on organ cultures of fetal mouse lung tissue. Organ cultures of fetal lung tissue from strain A mice 6-8 wk old exposed to DDT through the transplacental route showed intensive growth as compared to controls, a total of 1,076 DDT-exposed explants and 712 controls being examined. A dose of 50 ppm (parts per million) DDT induced a diffuse hyperplasia and focal proliferations, i.e. pre-adenomatous lesions, in the first generation. A progressively higher incidence of these lesions was observed at a dose level of 10 ppm, rising from 8.9% in the F₁ generation to 39.9% in the F₃ generation; however the incidence dropped in the F₄ and F₅ generations (30.1% and 20.1% resp.). Since no adenomas were observed in the present study the changes occurring in organ cultures of fetal lungs following intra-uterine exposure to DDT can only suggest a possible weak blastomogenic effect of DDT.

- 2996 THYMIC LYMPHOMA AND MYELOID LEUKEMIA IN THE RAT INDUCED WITH ETHYLNITROSOUREA. (E.) Hadjiolov, D. (Oncological Res. Inst., Sofia, Bulgaria). *Z Krebsforsch* 77:98-100, 1972.

A high incidence of thymic lymphoma and myeloid leukemia induced in rats with relatively small doses of ethylnitrosourea (ENU) is reported. Ten male Wistar rats were given monthly i.p. injections of 30 mg ENU and 20 rats received doses of 50 mg ENU; ten control rats received only saline. At the end of eight months all rats manifesting splenomegaly and orbital hemorrhaging were sacrificed and at ten months the experiment was terminated. Histologic findings on lymphatic tissues, kidney and tumors showed that among the first ten rats, three developed thymic lymphomas and three developed hyperplastic thymic lesions; among the other 20 experimental rats, nine developed thymic lymphomas, five, myeloid leukemia, and three, other neoplasms. It is not known why in some cases the myeloid tissue appears more susceptible to the carcinogenic action whereas in others the lymphoid tissue is susceptible.

- 2997 EFFECTS OF FEEDING THE CARCINOGEN DIMETHYLNITROSAMINE ON ITS METABOLISM AND METHYLATION OF DNA IN THE MOUSE. (E.) Den Engelse, L.

(Netherlands Cancer Inst., Amsterdam) and P. Lemelot. *Chem-Biol Interactions* 4(6):321-327, 1971/72.

The reversibility of dimethylnitrosamine (DMNA)-induced formation of 7-methylguanine (7-MeG) in lung, liver and kidney DNA was studied in C3H male mice. Animals received 10 ppm DMNA in their drinking water for six weeks. At the end of this period, DMNA-containing water was replaced by normal water. At various times after the start of the experiment, animals received a single i.p. injection of ^{14}C -DMNA, and 48 hr later the 7-MeG content of the DNA was determined. In addition, liver microsomal DMNA-N-demethylating activity was determined by measuring formaldehyde production *in vitro*, and blood DMNA concentration was assayed by gas chromatography. Pretreatment with DMNA strongly decreased methylation of liver DNA and stimulated methylation of both lung and kidney DNA. These effects were reversible, since normal or near normal methylation patterns were obtained when four to 11 weeks had elapsed between DMNA pretreatment and injection of labeled DMNA. A progressive, reversible inhibition of liver N-demethylase activity was also observed, which paralleled the changes seen in the methylation of liver DNA. DMNA took longer to appear in, and disappeared more slowly from, the blood of mice pretreated with DMNA than it did in the control mice, which had not been pretreated.

- 2998 DRUG-INDUCED CANCER. (E.) Fraumeni, J. F., Jr. (Nat'l. Cancer Inst., Bethesda, Md.) and R. W. Miller. *J Nat Cancer Inst* 48(5):1267-1270, 1972.

The carcinogenic capacity of drugs has been largely recognized as the result of animal experimentation and occupational studies. Current data on the oncogenic properties of various compounds have focused on: 1) radioisotopes; 2) immunodepressive drugs; 3) coal tar and creosote preparations; and 4) alkylating agents. Since the evidence for drug induced cancer is limited, recommendation for future investigations in this area should include surveillance of trends by cell type, age, sex and locale. In addition, the importance of the clinician is recognized in the reporting of clusters of cancers that are rare in the general population, particularly when the series has unusual demographic, clinical, occupational, familial or histopathologic characteristics. The establishment of new lines of communication among clinicians, experimentalists and epidemiologists are deemed necessary to provide impetus for studies into drug-induced cancer.

- 2999 INDUCTION OF LUNG TUMORS AND MALIGNANT LYMPHOMAS IN MICE BY METRONIDAZOLE. (E.) Rustia, M. (U. Nebraska Coll. Med., Omaha) and P. Shubik. *J Nat Cancer Inst* 48(3):721-729, 1972.

Metronidazole [1-(2-hydroxyethyl)-2-methyl-5-nitro-

imidazole], an anti-protozoal agent, was tested for carcinogenicity in a lifetime study in random-bred male and female Swiss mice. The drug was administered orally at levels of 0.5, 0.8, 0.15 or 0.06% of the powdered diet. None of the doses was toxic. The incidence of lung tumors, which were primarily adenomas, was significantly elevated, compared to controls, in animals receiving the three highest concentrations of metronidazole. The incidence of lung tumors in males (1/2) receiving a 0.5% metronidazole diet was significantly higher than that of the females (4%) of that group. No sex difference was seen in any of the other groups. Only females developed a significantly increased incidence of malignant lymphomas (primarily histiocytic and lymphocytic) at the two higher dose levels (0.5 and 0.1%) which was over twice that observed in the control animals. The latent periods observed for both lung tumors and lymphomas were probably not related to the frequencies of the neoplasms.

- 3000 POSSIBLE CARCINOGENICITY OF TAR-CONTAINING OINTMENTS. (Rus.) Shabad, L. M. (Inst.

Exp. Clin. Oncol., Moscow, USSR), A. B. Linnik, V. P. Tumanov and L. S. Rubetskoi. *Russkii Dokl* 16(6):6-9, 1971.

The possible carcinogenic effects of various tars and ointments prepared from these tars were studied in five groups of hybrid mice (C57 X CBA). The preparations were applied 2-3 times a week for 10-12 months, and the animals were observed for 1 1/2 years. Animals given coal tar containing 5190 $\mu\text{g/g}$ benzo(a)pyrene (BP) (18/19), those given Swiss "Ciba" coal tar containing 5020 $\mu\text{g/g}$ BP (20/21), and those given Locacorten tar ointment containing 225 $\mu\text{g/g}$ BP (16/17) died from tumors, while those given birch ointment 0.044 $\mu\text{g/g}$ BP and Vishnevskii ointment 0.0013 $\mu\text{g/g}$ BP survived with no tumor development. Birch tar was applied to the skin of Chinchilla rabbits and Vishnevskii ointment to the skin of six more rabbits twice a week for two years. None of these animals showed tumor growth. Thus, coal tar containing a large amount of BP (5190 $\mu\text{g/g}$) caused skin cancer, while Vishnevskii ointment with a low BP content (0.0013 $\mu\text{g/g}$) did not induce tumors.

- 3001 SUBCUTANEOUS INJECTIONS OF VACCINE ADJUVANT DEAE-DEXTRAN INDUCE LOCAL SARCOMAS IN MICE. (E.) Rice, J. M. (Nat'l. Cancer Inst., Bethesda, Md.) and R. M. Madison. *Nature New Biol* 236:28, 1972.

Female Swiss-Webster mice were given a single i.p. injection of the carcinogen 1-ethyl-1-nitrosourea (ENU) followed by weekly or twice weekly s.c. injections of DEAE-dextran in neutral, buffered saline for 10 to 20 wk. A total of 18 sarcomas were observed at the site of injection in 127 mice which were alive at the time when the first tumor was observed (25 wk after the first injection). Sarcomas developed whether or not mice also received poly I-poly C in the injec-

ions. No sarcomas developed in 42 mice (control) treated with ENU alone. Sarcomas also developed during the first yr of life in four of 48 mice which received DEAE-dextran injections, but no ENU. The incidences of other tumor types including mammary carcinoma, thymic lymphoma, and pulmonary adenoma were not significantly affected by repeated s.c. injections of DEAE-dextran in either ENU-treated or normal mice. It is concluded that DEAE-dextran was a non-reactive chemical carcinogen, with local but not systemic oncogenicity for rodent tissues.

002 CARCINOGENICITY OF HALO-ETHERS: II. STRUCTURE-ACTIVITY RELATIONSHIPS OF ANALOGS OF BIS(CHLOROMETHYL)ETHER. (E.) Van Duuren, B. L. Inst. Envir. Med., New York, N.Y.), C. Katz, B. M. Goldschmidt, K. Frenkel and A. Sivak. *J Nat Cancer Inst* 48(5):1431-1439, 1972.

Six chloro compounds related to the carcinogen bis(chloromethyl)ether were tested for carcinogenic activity by weekly s.c. injection for life in ICR/Ha mice and/or as initiating agents in 2-stage carcinogenesis on mouse skin. Two compounds, bis(α -chloromethyl)ether and 2,3-dichlorotetrahydrofuran, showed tumor-initiating activity. Of 20 mice, seven bore a total of nine papillomas with bis(α -chloroethyl)ether, and five of 20 mice bore papillomas and one bore a carcinoma with 2,3 dichlorotetrahydrofuran. All six compounds induced s.c. sarcomas in mice, but only two of the six, chloromethyl methyl ether (CMME) and bis(α -chloroethyl)ether, caused significant numbers of sarcomas at the injection site. None of the compounds induced significant incidences of tumors at sites distant from the injection site. Studies on the rate of hydrolysis of these six compounds and other related compounds tested earlier showed a good correlation between chemical reactivity and carcinogenicity. CMME and bis(chloromethyl)ether did not affect the melting point and buoyant density of salmon sperm DNA. The unlabeled compounds also did not yield simple alkylated products on reaction with purines. DNA under conditions in which other alkylating carcinogens, such as β -propiolactone and diepoxybutane, reacted. It is suggested that reactions with nucleic acids were not necessarily the critical step in chemical carcinogenesis by the chloro compounds tested.

003 SERIAL TRANSPLANTATION OF URETHAN-TREATED MAMMARY NODULE OUTGROWTH LINE D1. (E.) Medina, D. (Dept. Zool. Cancer Res. Genetics Lab., U. California, Berkeley). *J Nat Cancer Inst* 48(5):1371-1375, 1972.

Urethan-treated mammary nodule outgrowths were serially transplanted in various groups of mice for two or more generations. The urethan-treated outgrowths differed from methylcholanthrene (MCA)-treated outgrowths in two ways: 1) D1 nodule outgrowths exposed to urethan produced a high incidence of tumors (83%) if left *in situ*, continuing to yield tumors (32%) when retransplanted into untreated

mice. However, the tumor incidence decreases with successive transplant generations. 2) Urethan treatment did not alter the sensitivity of the nodule cells to hormone-mediated tumorigenesis. The oncogenic agents, urethan and mammary tumor virus (MTV), and urethan and MCA, were applied sequentially to D1 outgrowths. The results indicated that the effects of urethan and MTV, and urethan and MCA, were additive in the induction of mammary tumors. Thus, prior exposure of the outgrowths to urethan did not alter their responsiveness to MTV or MCA. These experiments provide no evidence that urethan interacts with MTV to promote mammary tumorigenesis in these nodule outgrowths.

3004 SERIAL TRANSPLANTATION OF METHYLCHOLANTHRENE-TREATED MAMMARY NODULE OUTGROWTH LINE D1. (E.) Medina, D. (Dept. Zool. Cancer Res. Genetics Lab., U. California, Berkeley). *J Nat Cancer Inst* 48(5):1363-1370, 1972.

Carcinogen-treated BALB/cCrgl mammary nodule outgrowths were serially transplanted into various groups of mice for two or more generations to determine the specific conditions for expression of the carcinogen-induced alterations. D1 nodule outgrowths exposed to 3-methylcholanthrene (MCA) produced a high incidence of tumors if left in the treated host, but failed to yield a significant number of tumors if transplanted as small pieces into untreated hosts. However, MCA-treated D1 outgrowths transplanted as whole glands onto the abdomens of untreated BALB/c mice and D1 outgrowths transplanted as small pieces into BALB/c mice with pituitary isografts produced a high incidence of mammary tumors. The serial transplantation of MCA-treated outgrowths for four generations into a series of MCA-treated hosts showed no accumulative effect of MCA on the tumor-producing capabilities of D1 outgrowths. The results are interpreted to mean that MCA treatment of nodule outgrowth line D1 leads to two separate and independent alterations. MCA increases the tumor-producing capabilities of nodule cells maintained in the hormonal milieu of a virgin mouse and also increases the susceptibility of nodule cells to the hormone-mediated tumorigenesis produced by pituitary isografts.

3005 STRAND SCISSION AND REJOINING OF DNA IN CULTURED MAMMALIAN CELLS INDUCED BY 4-NITROQUINOLINE 1-OXIDE. (E.) Andoh, T. (Inst. Med. Sci., U. Tokyo, Japan) and T. Ide. *Cancer Res* 32:1230-1235, 1972.

The effect of the carcinogen, 4-nitroquinoline 1-oxide (4NQO) on stationary cultured mouse fibroblasts, strain L-P3, a substrain of L-929, was studied. Cells were cultured in a protein- and lipid-free synthetic medium, DM-120. Strand breakage and repair of DNA caused by 4-NQO was examined. 4-NQO caused single- and double-strand breaks of DNA prelabeled with ^3H -

thymidine as shown by alkaline and neutral sucrose gradient centrifugation, resp. Breakage increased with increasing concentrations of carcinogen. At a concentration of $10^{-3}M$ 4-NQO, the DNA in the cells consisted either of a heterogeneous population of single-stranded molecules with sedimentation coefficients of 40 to 120S, or of an apparently homogeneous population of double-stranded 130S molecules, presumably containing single-strand breaks. Both the single- and double-strand breaks were repaired upon incubation of treated cells at 37 C in carcinogen-free medium. A 24 hr incubation was necessary for complete repair of double-strand breaks. Repair of single-strand breaks was complete by three hr. Repair of double-strand breaks was accompanied by the ability of treated cells to once again grow at a rate comparable to that of untreated controls.

- 3006 PROGESTIN SECRETION IN 3-METHYLCHOLANTHRENE-TREATED RATS. (E.) Moon, R. C. (U. Tennessee Med. Units, Memphis) and S. Young. *Int J Cancer* 9(2):402-408, 1972.

The mechanism of deciduomata maintenance by 3-methylcholanthrene (MCA) was investigated in normally cycling Sprague-Dawley rats. Animals received daily injections of ovine prolactin (LTH) from days 1-4 following estrus (pre-trauma period). On days 5 to 8 (post-trauma period), each rat received either daily injections of LTH, sesame oil intragastrically, or 10 mg 3-methylcholanthrene (MCA) in 1 ml sesame oil intragastrically. Other rats were either adrenalectomized, ovariectomized or hypophysectomized at the time of uterine traumatization on day 4. Results showed that rats which were not treated with LTH but in which the uterus was traumatized did not develop deciduomata, whereas 80% of rats treated with 5 IU LTH during the post-trauma period were positive. Rats receiving 10 IU LTH during the pre-trauma period but untreated during the post-trauma period did not develop deciduomata. However, 27% of rats were positive when fed oil during the post-trauma period. In the second experiment, 1 ml oil prior to and during the pre-trauma period resulted in all negative responses when oil was fed during the post-trauma period. All rats receiving LTH during the pre-trauma period followed by MCA during the post-trauma period were positive. None of the ovariectomized or hypophysectomized rats exhibited deciduomata when treated with MCA during the post-trauma period. However, 75% of the adrenalectomized rats showed positive reactions. These data indicate that MCA effects release of progesterin in quantities sufficient to maintain deciduomata and that both the pituitary gland and ovary are essential for this response.

- 3007 THE EFFECT OF GROWTH HORMONE, INSULIN AND ALLOXAN-INDUCED DIABETES ON CARCINOGENESIS IN THE GENITAL TRACT OF INTACT AND CASTRATE FEMALE RATS. (E.) Cherry, C. P. (Strangeways Res. Lab., Cambridge, England) and A. Glucksmann. *Brit J Cancer* 24(4):746-758, 1971.

Intact and castrate female Lister strain rats were given weekly intravaginal applications of a 1% solution of 9,10-dimethyl-1,2-benzanthracene (DMBA). Prior to the start of, and during the period of DMBA application, some intact and castrate rats received i.m. injections of protamine zinc insulin (1.2 U/day for 5 days/wk). Other intact and castrate rats were treated with a single i.p. injection of a 6% solution of Alloxan (150 mg/kg body wt) to induce diabetes prior to the DMBA applications. Still other intact and castrate rats received i.m. injections of bovine growth hormone (1 mg/rat, 5 days/wk) prior to and during DMBA application. All rats were weighed every two wk throughout the experiment. Sick or tumor-bearing animals were killed and autopsied. Castrate animals of all treatment groups were consistently heavier than intact animals under the same conditions. They also had more sarcomatous and epithelial cervico-vaginal neoplasms than the intact animals. Promotion of carcinogenesis and gain in body wt were independent phenomena caused by castration in the medicated rats. Growth hormone was the most effective in enhancing body wt in all animals, but was the least active tumor promoter. It reduced the incidence of sarcomas in intact rats, but increased that of epithelial neoplasms, and promoted both types in castrates. The highest incidence of cervico-vaginal epithelial and sarcomatous tumors occurred in spayed diabetics. Squamous cell epitheliomas of the vulva were not affected by castration or additional medication; however, basal cell carcinomas tended to be more frequent in intact rats than in castrates, and particularly numerous in unoperated diabetic rats who did not respond to insulin. Vulval sarcomas were usually rare but were increased in numbers in insulin-treated intact rats. Granular myoblastomas of the cervico-vaginal tract occurred in unoperated rats only, especially in diabetics and in growth hormone- or insulin-treated rats.

- 3008 DIETARY AFLATOXINS AND HUMAN LIVER CANCER: V. DURATION OF PRIMARY LIVER CANCER AND PREVALENCE OF HEPATOMEGALY IN THAILAND. (E.) Shank, R. C. (Dept. Nutr., Massachusetts Inst. Tech., Cambridge), P. Siddhichai, B. Subhamani, N. Bhamarapravati, J. E. Gordon and G. N. Wogan. *Fd Cosmet Toxicol* 10(3):181-191, 1972.

A study designed to determine the duration of primary liver cancer, based on hospital records of 271 patients from major hospitals in Bangkok and Chiang Mai, Thailand, from 1963 to 1969, is presented. Duration was defined as the interval between time of medical recognition of the cancer (day of report) and date of death; duration was measured to allow calculation of incidence from prevalence. To examine the relationship between aflatoxin intake and liver cancer it was necessary to measure frequency of liver cancer for rural and urban areas. Surveys were not practical in urban areas, partly due to population mobility. Quantitative information on liver cancer and hepatomegaly frequency was provided by a prevalence survey; two Thai provinces, Singburi and Songkhala, with a difference in liver cancer incidence, were selected for the rural field study.

The first province is an area of high aflatoxin intake, the second an area of low aflatoxin intake. Hospital records for the cities of Bangkok and Chiang Mai, which adjoin these two rural areas, indicated that 52% of the patients were less than 40 years old at time of death, with 25% under 40 yr. Primary liver cancer duration, as shown by autopsy biopsy was 1.5 months for 19 male patients aged 35-59 yr and 1.2 months for 41 males aged 50-59. Hepatomegaly rates in Singburi for males were twice those of females; the reverse relationship in Songkhala. It is thought that the results of the rural prevalence study are without statistical significance; however, it is suggested that liver cancer frequency in rural areas is similar to that in cities.

09 EFFECT OF THE CARCINOGEN N-NITROSOMETHYLUREA ON THE tRNA METHYLASE ACTIVITY OF CELLS CULTURED *IN VITRO*. (E.) Wilkinson, R. (Mancerson Labs, Manchester, England) and D. J. Linger. *Int J Cancer* 8:401-409, 1971.

tRNA methylase enzyme activity in a permanent line of these hamster ovary fibroblasts maintained *in vitro* was investigated in an attempt to detect early biochemical changes after treatment with N-nitrosomethylurea (NMU). Tumors were induced in 12 to six-wk-old female hamsters by cheek-pouch injections of 10^6 cells. Cloned populations from single cells surviving 80 μ g/ml NMU showed morphological conversion. Enzyme activity of cell-free extracts was determined by measuring 14 C methyl group incorporation from labeled S-adenosyl-L-methionine into methyl-deficient *E. coli* tRNA. Enzymes from T7 cells could introduce three times as many methyl groups into *E. coli* tRNA as those from N12 untreated cells at a protein concentration of 0.3 mg. No major qualitative differences were observed in tRNA bases methylated after NMU treatment. Elevation of methylase activity remained stable during six months of continuous cell culture. It is suggested that a permanent heritable alteration may have taken place after carcinogen exposure. However, it is as yet undetermined whether NMU exposure resulted in malignant conversion of the treated cells.

0 SPECIFIC VULNERABILITY OF THE LARGEST TELEOCENTRIC CHROMOSOME OF RAT BONE MARROW CELLS TO 7,12-DIMETHYLBENZ(a)ANTHRACENE. (E.) Sugiyama, (Ben May Lab. Cancer Res., U. Chicago, Ill.). *J Cancer Inst* 47(6):1267-1275, 1971.

Unbred, normal, male Long-Evans rats were injected i.v. with 50 mg/kg body wt 7,12-dimethylbenz(a)anthracene (DMBA) and killed at various times thereafter. Femoral bone marrow cells were prepared for chromosomal examination. A higher-than-expected incidence of chromosome aberrations was seen in the largest telocentric chromosome (C-1); aberration incidence in C-1 was 3.7, 2.5 and 2.0 times expected values in metaphases examined six, 12 and 24 hr after exposure, resp. Other chromosomes showed aberrations,

but only C-1 was vulnerable to aberrations six hr after DMBA. The C-1 chromosome appeared to be especially vulnerable to breaks in later interphase (late S or G2) or prophase. Two regions, 29 and 53% of the total length from the centromere of the C-1 chromosome, were especially susceptible to DMBA. The percentage of isochromatid lesions in six-hr C-1 specimens was 24.5% in the 29% region and 18% in the 53% region. The incidence of sister-chromatid exchanges was increased in DMBA-treated cells; chromatid exchanges after DMBA were preferentially induced in the two target sites of the C-1 chromosome, the 29% and 53% regions. The C-1 chromosome, and especially these two regions, replicated DNA late. The data were thought to suggest that two vulnerable regions of the C-1 chromosome were heterochromatic in nature.

3011 THE ROLE OF AVIATION IN POLLUTING THE HUMAN ENVIRONMENT WITH CARCINOGENIC HYDROCARBONS (3,4-BENZOPYRENE STUDY). (Ger.) Shabad, L. M. (Inst. Exp. Clin. Onkol. USSR, Moscow) and G. A. Smirnov. *Z Ges Hyg* 17(12):888-891, 1971.

Measurements of the amount of 3,4-benzo(a)pyrene (BP) in soot and exhaust gases from jet and turboprop aircraft engines, made by the Chesina modification of the Muel and Lacroix Method, disclosed that soot samples contained from 250 μ g-30 mg BP/kg soot, and that these engines emitted from 2-4 mg BP during one minute of flight. Because these emissions may contain other hydrocarbons, which act as promoters or inhibitors of BP, tests were performed on first-generation hybrid C57 x CBA mice. The effect of a 0.1% solution of chemically pure BP in benzene was compared with benzene extracts of soot from turboprop and piston engines, each of which contained 0.1% BP, and with pure benzene as a control. The solutions were applied to the skin of these mice, with each mouse receiving 50 applications. The test and control groups each included between 20 and 34 mice. Both benzene extracts of soot produced tumors in all of the mice tested, and pure BP induced tumors in 28/29 (96.5%) mice; no tumors developed in the controls. Of the tumors induced, 28/29 (96.5%) were malignant in the group treated with a benzene extract of soot from turboprop engines, 29/29 (100%) were malignant in the group treated with a benzene extract of soot from piston engines, and 26/28 (93%) were malignant in the group treated with a 0.1% solution of chemically pure BP. Most of the tumors were squamous-cell carcinomas, but there was one sarcoma and four carcinosarcomas. The BP content of soil from [5-7 cm below the surface of] the landing strip of the Moscow airport was 2-3 times greater than soil 10-12 cm from the surface, and the BP content of areas adjacent to taxiways was greater than areas near the landing strip. Grass growing next to runways contained 5.4-21.3 μ g BP/kg, and grass roots contained 3.1-7.0 μ g/kg. Snow on the landing strip contained 0.28-2.22 μ g/m² BP, depending upon the distance from the taxiway. These BP values were significantly larger than those obtained in control samples, showing that aviation causes environmental pollution.

- 3012 THE EFFECT OF TOBACCO SMOKE CONDENSATE ON RNA SYNTHESIS IN MOUSE SKIN. (Fr.) Alexandrov, K. (Inst. Sci. Res. Cancer, Villejuif, France) and C. Vendrely. *Chem-Biol Interactions* 4(3):155-161, 1971-1972.

3,4-Benzo(a)pyrene (BP) (20 µg in a 0.02% acetone solution), 0.1 ml of the initial condensate from tobacco smoke, 0.1 ml of a hexane extract of the initial condensate, or 0.1 ml of the residual fraction remaining after hexane extraction, was applied to the skin of male mice of the I.C. strain. As an RNA precursor, 10 µCi/g of ³H-orotic acid with a specific activity of 16 Ci/mMol was injected i.p. one hr before the mice were killed; radioactivity was measured with a Packard Tri-Carb spectrometer. The application of BP decreased the incorporation of orotic acid into skin RNA by 25-30% two hr after treatment. The initial condensate also inhibited RNA synthesis, but the effect occurred four hr after treatment, probably because this fraction is viscous and penetrates into the skin more slowly. The hexane fraction had the same effect as BP without a time lag, while the residual fraction doubled RNA synthesis during the 24 hr after application. The inhibition of RNA synthesis induced by carcinogens is interpreted as one step in the malignant transformation of tissues, particularly in the tumor initiation stage.

- 3013 REGRESSION AND RECURRENCE OF MAMMARY TUMOR PRODUCED WITH 7,12-DIMETHYLBENZ(a)ANTHRA-CENE (DMBA) IN RATS. (E.) Imaizumi, T. (Jikei U. Sch. Med., Japan) and I. Ohira. *Jikei Med J* 18:1-5, 1971.

Female Sprague-Dawley rats (six wk old, 150 g) were treated as follows: Group I received a single feeding of 1 ml olive oil by gastric intubation (ten rats). Group II received a single oral feeding of 10 mg of 7,12-dimethylbenz(a)anthracene (DMBA) dissolved in 1 ml olive oil (ten rats). Group III received 10 mg DMBA by gastric intubation. On the 41st day after the carcinogen administration these females were allowed to mate at will (five rats for DMBA and parturition, resp.). Group IV received 1 ml olive oil and was allowed to mate as Group III (five rats). Pregnant animals in both groups III and IV were allowed to nurse the entire litters for 28 days. Induced tumors were detected by palpation. All animals were observed for approximately 12 months, and at necropsy all tumors were prepared for microscopy. Animals which received only olive oil at six wk of age (Group I and IV) did not develop mammary tumors. Administration of a single dose of 10 mg DMBA resulted in development of mammary tumors in 14 of 15 animals (Group II and III). In three cases of Group III and one case of Group II, regression of mammary tumors were observed. In further observations, mammary tumors recurred on sites different from the initial sites.

- 3026 RISK FACTORS OF SKIN CANCER. (Ger.) Luger, A. (Vienna, Austria). *Deut. Erforsch. Bekämp. Krebkrankh.* 26(5):372-373, 1971.

The causes of skin cancer, the most important of which is sunlight, are discussed. Although UV radiation in sunlight damages cell chromosomes, the damage can be repaired, but the extent of repair is limited. Skin pigmentation acts as a protective mechanism. The critical exposure time for skin cancer ranged from 40,000-180,000 hr, depending upon the ability of the individual to produce pigment. The author's analysis of 1267 cases of skin cancer and another 9541 cases reported in the literature demonstrates that 86.6% of all squamous-cell carcinomas are located on the face or neck in sites ordinarily exposed to light (nose, ear, lower lip, lower eyelid, back of the hands). The incidence of skin cancer reaches a maximum at age 71.3 yr. Skin cancer is found more in persons engaged in outdoor occupations than in factory workers. Prolonged exposure to small doses of ionizing radiation can also induce skin cancer: x-ray technicians, assistants, and physicians have a high risk for this form of cancer. Other risk factors for skin cancer include chronic inflammations of the genitalia which cause prickle-cell carcinomas; ingestion of arsenic-containing drugs, which induce multiple basal-cell carcinomas; scarring from burns, lupus vulgaris, or lupus erythematosus; and smoking which causes lip cancer because of the photosensitizing effect of tobacco tar.

- 3027 OTHER TUMORS. (E.) Steer, A. (Atomic Bomb Casualty Commission, Hiroshima, Japan). *Human Path* 2(4):541-546, 1971.

Life span study cases from the Atomic Bomb Casualty Commission (ABCC) and from the Hiroshima and Nagasaki tumor registry files were reviewed in order to determine whether or not A-bomb irradiation was associated with cancers of various organs. Although a relationship between exposure to A-bomb irradiation and the incidence of breast cancer in Japanese women has not been established, evidence suggests a possible association. The occurrence of gynecologic cancer among members of the Life Span Study Sample has been studied on several occasions with questionable evidence of an association of ovarian, uterine, or cervical cancer with radiation exposure at the time of the A-bombs. A review of related pathology material at ABCC showed no increase in gallbladder carcinoma in the heavily irradiated group as compared to a nonexposed group. Malignant salivary gland tumors showed a significant increase ($P < 0.001$) in the heavily irradiated group. Although benign salivary gland tumors were also more frequent in the irradiated group, the increase was not significant ($P > 0.05$). A study of leukemogenesis and carcinogenesis in offspring of women exposed to A-bomb irradiation while pregnant showed no significant excess in mortality when compared to controls not exposed to irradiation. Although children exposed to A-bomb irradiation showed no excess of neoplasms in general, an excessive increase in leukemia

($P < 0.0001$) and possibly an increase in breast cancer were observed. Children exposed to a 165 dose in excess of 100 rads have also shown an excessive number of thyroid malignancies with a latent period of about 15 yr. Preliminary studies of multiple primary malignant tumors have indicated that the carcinogenic effect of A-bomb irradiation was not additive in the sense of producing multiple malignant neoplasms.

- 3028 EXPERIMENTAL LUNG CANCERS PRODUCED IN THE RAT BY RADON INHALATION. (Fr.) Gamaud, J. (Atomic Energy Commission, Bazel, France), R. Perraud and J. Lafuma. *Int. Assoc. Radiat. Biol.* 27(23):2388-2389, 1971.

Rats were exposed to atmospheres containing a mean concentration of 130 mg/m^3 uranium mineral dust 15 times for a total of 50 hr, a mean concentration of 6×10^{-7} curies/liter of radon 125 times for a total of 620 hr, or to both radon and dust. All 34 surviving rats exposed to radon, either alone or associated with dust, developed various types of bronchopulmonary carcinomas (alveolar cell carcinomas, adenocarcinomas, rather well-differentiated squamous cell carcinomas). Some tumors were made up of several different histological types; small cell carcinomas were not found. After 21 months no cancer had developed in any of the controls or in rats exposed to mineral dust. These findings show that large doses of radon can induce lung cancer in animals exposed to it; it is not necessary to first expose the animals to dust. Exposure to the dust appeared to retard the appearance of tumors by about one month.

- 3029 RADIATION CARCINOGENESIS AT LOW DOSES. (E.) Rossi, H. H. (Coll. Physicians Surg. Columbia U., New York, N.Y.) and A. M. Kellner. *Science* 175(4018):200-202, 1972.

Radiations of high linear energy transfer (neutrons) are experimentally applied to Sprague-Dawley rats serving to clarify some of the issues involved in determining existence of a "threshold dose". Previous studies of x-rays have shown a linear dependence of incidence of mammary rat neoplasms on dose while results for neutrons have been less consistent with linearity. Even if the dose-effect relation for x-rays were linear in the high dose range previously studied, linear extrapolation to lower doses is unjustified. The neutron dose-effect curve and microdosimetric determinations imply that the development of malignancies are determined by radiation effects on a number of interacting cells.

- 3033 HERPES SIMPLEX VIRUS LATENCY IN CULTURED HUMAN CELLS FOLLOWING TREATMENT WITH CYTOSINE ARABINOSIDE. (E.) O'Neill, F. J. (Milton S. Hershey Med. Ctr. Pennsylvania St. U., Hershey), R. J. Goldberg and F. Rapp. *J Gen Virol* 14:189-197, 1972.

Human embryonic lung (HEL) cells infected with herpes simplex virus type 2 (HSV-2), strain 316-D, were treated with cytosine arabinoside (ara-C) in an effort to obtain non-productively infected HEL cultures. Exposure of cultures to 10 or 20 µg/ml ara-C starting 24 hr prior to HSV-2 infection totally inhibited virus synthesis by four days after inoculation. The inhibition continued through nine days post-infection. Microscopic examination of inhibited cultures revealed normal cell morphology. Removal of ara-C after up to 22 days of treatment resulted in recovery of infectious virus after a delay of 6 to 11 days. The reappearance of infectious virus coincided with the appearance of virus CPE. The period between the disappearance and reappearance of infectious virus was defined as the "latent period" (days 4 to 13 after infection). The ability of latent period cultures to support the replication of HSV-2 or vesicular stomatitis virus indicated that ara-C was not preventing virus expression by a toxic effect. Infectious center assays showed that as many as 1 in 800 latent period cells were capable of ultimately synthesizing infectious virus.

- 3034 SEROLOGIC EVIDENCE FOR A SIMIAN-VIRUS-40-LIKE INFECTION OF MAN. (E.) Shah, K. V. (Johns Hopkins Sch. Hyg. Public Hlth., Baltimore, Md.), F. R. McCrumb, Jr., R. W. Daniel and H. L. Ozer. *J Nat Cancer Inst* 48(2):557-561, 1972.

Sera from four groups of donors were tested for the presence of SV40-reacting antibodies. Neutralizing antibodies were found in about 20% of the sera of Maryland children born between 1955 and 1957. This group had a high risk of having received SV40 contaminated Salk poliomyelitis vaccine. SV40-neutralizing antibodies were also found in nine (3.2%) sera of a low-risk group of Maryland children born between 1964 and 1968. SV40-reacting antibodies were detected in four of 200 sera collected from adults in 1951 and 1954 before monkey kidney vaccines came into general use. The validity of the results from neutralization tests was confirmed by indirect immunofluorescence and radioisotope precipitation tests. These results strongly suggest that man may become infected with an SV40-like virus without being exposed to monkeys or monkey products.

- 3035 SPECIFIC IMMUNOFLUORESCENCE TEST FOR DETECTION OF HERPESVIRUS ANTIGEN IN CELLS OF THE LUCKE RENAL ADENOCARCINOMA. (E.) Paul, S. M. (Chapman H. Hyans III Lab. Tumor Cell Biol., Tulane U., New Orleans, Louisiana), M. Mizell, B. Craige, J. Blazek and M. Skinner. *Proc Soc Exp Biol Med* 139(3):944-948, 1972.

A fluorescent antibody technique has been developed

which detects viral antigen(s) in the winter state (virus-containing) of the Lucké renal adenocarcinoma of *Rana pipiens*. Antiserum prepared against purified herpesvirus fractions of the Lucké tumor was used to detect the virus-containing nature of various tumor samples. A strong positive reaction was elicited against two different virus fractions similar to those used for preparation of the antiserum. Winter tumor frozen sections gave bright fluorescence in the nucleus and cytoplasm when stained with immune rabbit serum in the indirect immunofluorescence (IF) test. Normal kidney and summer (nonviral) tumor sections consistently gave negative IF results. The IF test was thus specific for the virus-containing state of the Lucké tumor and has been used successfully in detecting the virus-containing components of various tumor samples.

- 3036 CONTINUOUS LONG-TERM REPLICATION OF FELINE LEUKEMIA VIRUS (FeLV) IN AN ESTABLISHED CANINE CELL CULTURE (MDCK). (E.) Essex, M. (U. California, Davis), T. G. Kawakami and K. Kurata. *Proc Soc Exp Biol Med* 139(1):295-299, 1972.

The growth properties and immunological parameters of cultures of uninfected and FeLV-infected Madin-Darby canine kidney cells (MDCK) were studied. The growth curves of uninfected and infected MDCK cells were similar. Cultures lagged for one day after inoculation and then grew logarithmically. Examination by light microscopy revealed no cytopathic effect or loss of contact inhibition in FeLV-infected MDCK cells. Pellet preparations obtained by ultracentrifugation of infected MDCK culture fluid from passages 8, 12, 22, 33 and 57 gave a strongly positive complement fixation test using antiserum to purified FeLV. Culture fluids from infected cells at passages 5, 22, 33 and 57 were similarly positive using the gel precipitation technique. Examination of infected cells at passages 8, 33 and 57 by electron microscopy showed budding and mature C-type particles typical of FeLV. C-type particles were also observed in the 1.13 to 1.17 g/cm³ density fraction from FeLV-infected MDCK culture fluids. These results demonstrate that an established cell line of canine origin could support the replication of FeLV in a steady-state noncytotoxic manner.

- 3037 STUDIES ON THE HYPERPLASTIC FOCUS FORMATION BY VARIOLA VIRUS IN HUMAN CELL CULTURES: III. VIRUS GROWTH AND FOCUS FORMATION IN HeLa CELLS CULTURED AT SUPRAOPTIMAL TEMPERATURES. (E.) Kitamura, T. (Natl. Inst. Hlth., Tokyo, Japan). *Japan J Med Sci Biol* 24(3):153-162, 1971.

Variola virus growth and hyperplastic focus formation in HeLa cells cultured at temperatures higher than 37°C were studied. Virus growth was inhibited by 98% at 37.5°C, whereas the efficiency of focus formation was not changed. At 38.0°C the growth of virus was almost completely inhibited, while the number of

oci formed was reduced only to 30 to 50% of those formed at 37 C. At temperatures higher than 38.5 C both virus growth and focus formation were completely inhibited. The interaction between variola virus and HeLa cells leading to focus formation was analysed by exposing the infected cultures to 40 C for a limited period of time at various intervals after infection. Virus adsorption and penetration into HeLa cells were rather accelerated at 40 C. Shifting the incubation temperature of the infected cultures from 37 C to 40 C at any time after infection resulted in interruption of the virus growth. It was also indicated that 30 to 36 hr at 37 C were necessary for visible foci to develop even after the shift up, suggesting that micro-foci formed during this period and that subsequent cell aggregation took place at 40 C. Shift down experiments from 40 C to 37 C indicated that initial incubation at 40 C for longer than 36 hr impaired greatly the efficiency of focus formation after shift down, probably due to the thermal degradation of penetrated virus.

038 IDENTIFICATION OF VIRUS-INDUCED PROTEINS IN CELLS PRODUCTIVELY INFECTED WITH SIMIAN VIRUS 40. (E.) Fischer, H. (German Cancer Res. Ctr., Heidelberg) and G. Sauer. *J Virol* 9(1):1-9, 1972.

The number and molecular wt of the structural polypeptides of highly purified SV40, strain Rh911, were determined by polyacrylamide gel electrophoresis. Six different polypeptides were found, two of which (VP1 and VP2) comprised the bulk of the viral capsid proteins. The pattern of protein synthesis in productively infected CV-1 cells was studied by sodium dodecyl sulfate polyacrylamide gel electrophoresis. Identification of virus-induced proteins in the infected CV-1 cells was achieved in double-labeling experiments by electrophoresis with purified labeled SV40 capsid proteins. Four of these proteins (VP1-VP4) were classified as virion components as synthesis occurred after the onset of viral DNA replication (18 hr post-infection) and since the synthesis of these proteins was inhibited by arabinofuranosylcytosine (ara-C). Appearance of two other virus-induced proteins was not prevented by ara-C; one of them did not comigrate in electrophoresis with purified virion polypeptides, and both could be detected before the onset of viral DNA synthesis. These latter two proteins were classified on the basis of these criteria as nonvirion capsid proteins (NCVP1 and NCVP2).

039 DETECTION AND ASSAY OF AVIAN TUMOR VIRUS GROUP-SPECIFIC ANTIGEN AND ANTIBODY BY THE PAIRED RADIOIODINE-LABELED ANTIBODY TECHNIQUE. (E.) Leber, J. (Dept. Vet. Path., Ohio St. U., Columbus) and D. S. Yohn. *J Virol* 9(2):244-250, 1972.

The paired radioiodine-labeled antibody technique (PRILAT) was employed to measure avian leukosis group-specific (gs) antigens and antibody in Rous sarcoma virus (RSV)-induced tumor and transformed cell lines from hamsters, chickens, turkeys and pigeons. The technique was specific and reproducible, and

proved to be more sensitive than the microcomplement-fixation test for avian leukosis (COFAL) as evidenced by the ability to detect gs antibody in COFAL-negative sera from hamsters bearing RSV-induced tumors. The PRILAT method was used to detect the relative gs content of the various tumor and RSV-transformed cells. These results were confirmed by immunofluorescence and complement fixation tests. Sera from chickens bearing RSV-induced wing web tumors were not positive for gs antibodies; however, sera from pigeons, chickens and turkeys immunized with avian leukosis virus reacted in direct PRILAT inhibition and/or indirect PRILAT tests.

3040 HYBRIDIZATION OF ROUS SARCOMA VIRUS DEOXYRIBONUCLEIC ACID POLYMERASE PRODUCT AND RIBONUCLEIC ACIDS FROM CHICKEN AND RAT CELLS INFECTED WITH ROUS SARCOMA VIRUS. (E.) Coffin, J. M. (McArdle Lab., U. Wisconsin, Madison) and H. M. Temin. *J Virol* 9(5):766-775, 1972.

Rous sarcoma virus (RSV)-specific RNA prelabeled with ³²P in virus-producing chick embryo fibroblasts and non-virus-producing rat embryo fibroblasts infected with RSV was studied by hybridization with the endogenous DNA product of the RSV virion DNA polymerase system. By hybridizing the total DNA product with excess virion RNA, the product DNA was separated into hybridized ("minus") and nonhybridized ("plus") DNA. The "minus" DNA was complementary to at least 20% of the RNA from RSV which remained of high molecular wt. after denaturation. A maximum of approximately 65% hybridization was observed between "minus" DNA and RSV RNA or RSV-infected chick cell RNA. A maximum of about 60% hybridization was measured between "minus" DNA and RSV-infected rat cell RNA. RSV-infected chicken cells contained RSV-specific RNA equivalent to about 6,000 virions per cell. RSV-infected rat cells contained RSV-specific RNA equivalent to approximately 400 virions per cell. Neither cell type contained detectable RNA complementary to virion RNA. The RSV-specific RNA in RSV-infected rat cells did not appear to be qualitatively different from that in RSV-infected chick cells.

3041 VIRUS-INDUCED INTERFERENCE IN HETEROLOGOUSLY INFECTED HeLa CELLS. (E.) Doyle, M. (Dept. Biol., U. California, San Diego, La Jolla) and J. J. Holland. *J Virol* 9(1):22-28, 1972.

The replication of virus and synthesis of viral proteins and nucleic acid were studied in HeLa cells doubly infected with polio-virus type 1 and vesicular stomatitis virus (VSV). Addition of poliovirus to cultures preinfected with VSV, at any time before completion of VSV macromolecular synthesis (up to eight hr post-infection), led to marked inhibition of VSV replication as determined by plaque assay. Replication of poliovirus was apparently unaffected by the presence of VSV. Replication of

poliovirus was not necessary for interference with VSV replication. Superinfection by poliovirus of cells preinfected with VSV shut off incorporation of ^3H -amino acids into VSV-specific proteins within two hr. However, poliovirus had little, if any, direct effect on incorporation of ^3H -uridine into VSV RNA. A decrease in VSV RNA synthesis late in infection in the presence of poliovirus was probably a secondary effect of the earlier inhibition of VSV protein synthesis. Similar experiments using coxsackievirus B₁ showed that it also was able to inhibit VSV replication and protein synthesis in doubly infected cells without affecting VSV RNA synthesis. It is concluded that poliovirus interfered with VSV virion production only at the translational level of viral messenger RNA.

- 3042 ANTIBODIES TO EB VIRUS CAPSID ANTIGEN AND TO SOLUBLE ANTIGEN OF LYMPHOBLASTOID CELLS IN INFECTIOUS MONONUCLEOSIS PATIENTS. (E.) Vonka, V. (Inst. Sera Vaccines, Prague, Czechoslovakia), I. Vlckova, H. Zavadova, K. Kouba, J. Lazovska and J. Duben. *Int J Cancer* 9(3):529-535, 1972.

Sera from infectious mononucleosis (IM) patients aged 2 to 35 yr and from normal subjects aged 11 to 35 yr were examined for the presence of antibody to Epstein-Barr (EB) virus capsid antigen (VCA) by the indirect immunofluorescence test, and for antibody reactive with the soluble (S) antigen of lymphoblastoid cell lines by the complement-fixation test. Sera from all IM patients taken either in the acute stage of the disease or up to nine yr after its onset contained VCA antibody. The sera taken in the acute stage of IM were free of S antibody; out of 97 sera examined only one was weakly reactive. Only one of the seven sera taken 4 to 5 months after the onset of the disease contained S antibody; however, S antibody appeared in the majority of the subjects after the seventh month following onset. These data indicate that the S antibody appears much later in the course of EB virus infection than the VCA antibody. The majority of sera from subjects with no history of the disease possessed VCA antibody; most of these also possessed S antibody. The incidence of S antibody in these people was the same as that in patients who had suffered from IM nine yr previously.

- 3043 ABSENCE OF LEUKOSIS VIRUS MARKERS IN HAMSTER CELLS TRANSFORMED BY HERPES SIMPLEX VIRUS TYPE 2. (E.) Rapp, F. (Milton S. Hershey Med. Ctr., Pennsylvania St. U., Hershey), R. Conner, R. Glaser and R. Duff. *J Virol* 9(6):1059-1063, 1972.

Hamster embryo fibroblasts transformed by UV-inactivated herpes simplex virus type 2 (HSV-2) were tested by various means for the presence or absence of RNA tumor virus information. Medium from HSV-2 transformed cells prelabeled with ^3H -uridine contained no labeled C-type particles which characteristically band in sucrose gradients at 1.16 gm/cm³. Complement fixation and indirect immunofluorescence tests failed to detect

species-specific gs-1 and interspecies gs-3 antigens in all five HSV-2 transformed cell lines whether or not they were exposed to bromodeoxyuridine or iodo-deoxyuridine. Direct electron microscopic observation also failed to show C-type particles, although incomplete herpes-like particles were seen within nuclei and budding from nuclear membranes of a small number of cells. These results are inconsistent with the oncogene theory of cellular transformation and suggest that C-type particles or their genome do not play an obvious role in the maintenance of HSV-2 transformed hamster cells.

- 3044 EARLY STAGES OF ROUS VIRUS ACTION ON SENSITIVE AND RESISTANT CELLS. (E.) Dyadkova, A. M. (N. N. Petrov Res. Inst. Oncology, Leningrad, USSR), O. K. Kuznetsov and G. A. Sovostjyanov. *Neoplasma* 19(3):157-162, 1972.

The course of Rous sarcoma virus (RSV) infection of RSV-sensitive chick embryo cells and of RSV-resistant human embryo cells was studied by electron microscopy and indirect immunofluorescence. Both sensitive and resistant cells incorporated virus particles (by pinocytosis and phagocytosis) to the same extent. By two to three hr post-infection, the number of recognizable virus particles had decreased significantly in sensitive cells. Such a decrease, however, was not apparent in resistant cells. Some virus particles were extruded from resistant cells into the intercellular spaces. The indirect immunofluorescence method revealed that the incidence of viral antigen was greatly reduced in sensitive cultures (5-7% of the cells) after one hr and that viral antigen was undetectable after six hr. Viral antigen was present in 26-63% of the resistant cells after one hr and it did not completely disappear until 72 hr post-infection. It was thus assumed that virus particles in resistant cells remained undamaged for longer periods than those in sensitive cells which rapidly undergo uncoating.

- 3045 THE FORMATION OF VARIANTS WITH A REVERSION OF PROPERTIES OF TRANSFORMED CELLS: VI. STABILITY OF THE REVERTED STATE. (E.) Rabinowitz, Z. (Weizmann Inst. Sci., Rehovoth, Israel) and L. Sachs. *Int J Cancer* 9(2):334-343, 1972.

The stability of the reverted state was analyzed in revertants from polyoma-virus-transformed hamster cells in which reversion was not associated with a loss of the viral genome. The frequency of reversion was studied in 12 cloned revertants after different periods of *in vitro* cultivation. The regaining of two transformed properties, the ability to form colonies at 41 C and in soft agar, were used as markers for reversion. No temperature re-revertants and 2 to 184 agar re-revertants per 5 x 10⁴ cells were detected 45 days after isolation of the clones. At 90 days after isolation, there were 14 to 784 temperature re-revertants and 242 to 1160 agar re-

revertants per 5×10^4 cells. Thus, the stability of the reverted state was decreased by *in vitro* cultivation. A study of the isolated re-revertants indicated that once a transformed property has been regained during re-reversion, the immediate progeny of the re-revertants may contain a high frequency of segregants which had lost this regained property. The re-reverted state was more stable in re-revertants isolated from revertants 100 days after cultivation than in re-revertants from revertants cultured for 55 days. Re-reversion for one transformed property was not necessarily associated with re-reversion for the other transformed property. The different degrees of stability of the reverted state could possibly be explained by differences in the presence of chromosomes responsible for either expression or suppression of the transformed properties.

046 A NON-FUNCTIONAL ARGININE BIOSYNTHETIC PATHWAY IN POLYOMA INFECTED-MOUSE EMBRYO CELLS. (E.) Winters, A. L. (Div. Biol., Kansas State U., Manhattan), R. A. Consigli and Q. R. Rogers. *Biochem Biophys Res Commun* 47(5):1044-1050, 1972.

The arginine biosynthetic pathway was studied in polyoma virus-infected primary mouse embryo cells which showed a strict arginine requirement for viral replication. During viral replication, equimolar concentrations of citrulline substituted for arginine, but equimolar or ten times equimolar concentrations of ornithine did not replace arginine. Amino acid analysis of purified viral preparations prelabeled with either ^{14}C -ornithine or ^{14}C -citrulline showed that citrulline was metabolized to arginine but that ornithine was converted primarily to proline and glutamic acid with no label appearing in arginine. Assay of ornithine carbamoyltransferase (OCT) activity in cell-free lysates showed that this enzyme was not lacking in infected cells. Therefore, the inability of ornithine to serve as an arginine precursor in infected cells appeared to be due to the fact that it was used by ornithine- δ -transaminase to synthesize proline and glutamate rather than by OCT to synthesize citrulline. It is concluded that the arginine biosynthetic pathway is non-functional in polyoma-infected mouse cells.

047 RNA-DEPENDENT DNA POLYMERASE ACTIVITY OF RNA TUMOR VIRUSES: I. DIRECTING INFLUENCE OF DNA IN THE REACTION. (E.) Hurwitz, J. (Albert Einstein Coll. Med., Bronx, N.Y.) and J. P. Leis. *Virology* 9(1):116-129, 1972.

The template requirements and DNA products of the DNA polymerases isolated from Rauscher leukemia and avian myeloblastosis viruses have been examined. All DNA preparations or synthetic polydeoxynucleotides which were active as primers possessed a duplex structure containing single-stranded regions with a 3'-hydroxyl terminus. Native DNA and fully single-stranded DNA

were inactive; moreover, their activity was not enhanced by sonic oscillation or treatment with micrococcal or *Neurospora* nuclease, or by low levels of DNase I. Poor DNA templates were activated by treatment with *E. coli* exonuclease III, large amounts of DNase I, or an endonuclease isolated from Rauscher viral preparations. In reactions primed with deoxyadenylate-deoxythymidylate copolymer, the product formed was covalently attached to primer strands, indicating that no new strands were initiated. DNA polymerase products formed with exonuclease III- or DNase I-treated DNA were duplex structures. Short single-stranded regions were completely repaired, whereas long single-stranded regions were only partly repaired. DNA preparations containing extensive single-stranded regions were poorly utilized as templates.

3048 SYNTHESIS AND ASSEMBLY OF SIMIAN VIRUS 40: I. DIFFERENTIAL SYNTHESIS OF INTACT VIRIONS AND EMPTY SHELLS. (E.) Ozer, H. L. (Nat'l. Cancer Inst., Bethesda, Md.). *J Virology* 9(1):41-51, 1972.

The synthesis and assembly of SV40 in Vero cells was studied. A rapid procedure enabling the purification and separation of radioactively labeled virions and empty shells was developed. ^3H -amino acid-labeled, infected cells were harvested late in infection before gross cytopathic changes occurred. Virus was extracted by sonic treatment and the low-speed supernatant was sedimented through sucrose into a CsCl "cushion". Two radioactive peaks in the CsCl cushion were identified by electron microscopy as intact virions (>90% purity) and empty shells (80-85% purity). Labeled intact virions analyzed by polyacrylamide gel electrophoresis contained four major proteins of 45,000 (I), 23,000 (II), 15,000 (IIIA) and 13,000 (IIIB) daltons. Electrophoretic analysis of empty shells indicated that they contained a relatively decreased amount of peaks IIIA and IIIB. Cells were labeled with ^3H -lysine for periods of 15 minutes to two hours beginning 72 hours post-infection and viral particles were purified and analyzed by electrophoresis. As much as 5-10% of the total acid-precipitable radioactivity was incorporated into viral particles in a two hour label. For all labeling periods, more than 60% of the radioactivity incorporated into viral proteins was associated with the major capsid protein. Predominant labeling of empty shells occurred in short (1-3 hr) pulses while prolonged labeling periods (16-24 hr) routinely resulted in more radioactivity in intact virions. Treatment of cells with cytosine arabinoside late in infection caused a 50% inhibition in the rate of synthesis and/or assembly of intact virions with little change in the rate of appearance of empty shells. It is believed that empty shells are likely heterogeneous in biological origin as well as structure. Evidence from this investigation supports either of two possibilities: (i) that empty shells are synthesized independently of intact virions and (ii) that empty shells result from breakdown of previously synthesized, intact virions. A third possibility - that empty shells are precursors of intact virions - is discussed in a subsequent paper.

- 3049 AN ESTABLISHED RIII MOUSE MAMMARY TUMOR CELL LINE; KINETICS OF MAMMARY TUMOR VIRUS (MTV) PRODUCTION. (E.) Lasfargues, E. Y. (Inst. Med. Res., Camden, N.J.), B. Kramarsky, N. H. Sarkar, J. C. Lasfargues and D. H. Moore. *Proc Soc Exp Biol Med* 139(1):242-247, 1972.

A cell line was established from a soft spontaneous mammary tumor which occurred in an RIII mouse. The cell line, RIII-MT, was epithelial. Thin sections of the cultures prepared at 2-3 month intervals during the three yr of cultivation have consistently shown the presence of intracytoplasmic A-type particles and also B-type particles budding from the cell membrane. C-type particles associated with the leukemia-sarcoma system have not been found. Mammary tumor virus (MTV) antigen was detected in the third lactation milk of 34 out of 42 C57BL female mice inoculated with culture fluids. Several of these animals developed mammary tumors; none developed leukemia. Inoculation of 4×10^6 RIII-MT cells into newborn RIII mice resulted in infiltrating carcinomas at the site of injection. The MTV produced at the cell surface of RIII-MT cells was not spontaneously released. Harvest of the virions was obtained by cell dispersion with trypsin followed by storage for seven days at 4 C. After refrigeration, the virus retained its full infectivity.

- 3050 PROTEINS SPECIFIED BY HERPES SIMPLEX VIRUS: V. PURIFICATION AND STRUCTURAL PROTEINS OF THE HERPESVIRION. (E.) Spear, P. G. (Dept. Microbiol., U. Chicago, Illinois) and B. Roizman. *J Virol* 9(1):143-159, 1972.

Herpes simplex virus was purified from infected human epidermal carcinoma no. 2 (HEp-2) cells. Cells were disrupted and the cytoplasm was separated from the nuclei. The cytoplasmic extract was subjected to rate zonal centrifugation on dextran 10 gradients to separate virions from soluble proteins. The virions were further purified by centrifugation through discontinuous sucrose gradients. Virion proteins were purified 120 to 200-fold with respect to cellular proteins. Residual contaminants were identified as host cell and viral constituents of membrane vesicles. Evidence suggested that the contaminating host proteins were not structural components of the virion. Analysis of purified virion preparations by polyacrylamide gel electrophoresis revealed 24 protein and glycoprotein bands. The glycoproteins, identified by their ability to incorporate ^{14}C -glucosamine, were selectively lost during the isolation procedure. Electrophoretic comparison of these ^{14}C -labeled glycoproteins with glycoproteins from uninfected cells and purified virions suggested that they were present both in contaminating membrane fragments and in the virion. The average molecular wt of the viral proteins as determined by polyacrylamide gel electrophoresis ranged from 25,000 to 275,000 daltons. The sum of the molecular wt of viral proteins was 2,580,000 daltons. This corresponded to 47% of the genetic information of the virus. Treatment of purified virions with the non-ionic detergent NP-40 removed some of the nonglycosy-

lated and many of the glycosylated proteins. Although NP-40 destroyed the normal morphology of the virion envelope, it did leave behind traces of the envelope visible in the electron microscope as well as some glycoproteins thought to be components of the envelope.

- 3051 IMMUNOELECTROPHORETIC ANALYSIS OF AVIAN RIBONUCLEIC ACID TUMOR VIRUS GROUP-SPECIFIC ANTIGENS. (E.) Bonar, R. A. (Duke U. Med. Ctr., Durham, North Carolina), R. Ishizaki and J. W. Beard. *J Virol* 9(1):90-95, 1972.

Fifteen pigeons inoculated with the Schmidt-Ruppin strain of Rous sarcoma virus (SR-RSV) developed tumors. In all 13 surviving birds, the tumors began to regress about six wk after inoculation. Sera from these pigeons, taken eight wk after inoculation, had complement-fixing group-specific antibody titers of 1:2 to 1:256. Immunoelectrophoresis of disrupted BAI strain A (myeloblastosis) avian tumor virus with pigeon serum showed at least five precipitation arcs. The pattern of precipitation lines was dependent in part on the means used for virus disruption, and ethyl ether and nonionic detergents appeared to be both effective and relatively mild reagents. Immunoelectrophoretic comparison of pigeon serum with serum from a tumor-bearing hamster and that from virus-inoculated rabbits yielded very similar, although not identical, results.

- 3052 GENETICALLY STABLE REASSORTMENT OF MARKERS DURING MIXED INFECTION WITH AVIAN TUMOR VIRUSES. (E.) Vogt, P. K. (U. Washington Sch. Med., Seattle). *Virology* 46(3):947-952, 1971.

The cloning experiments described indicate that mixed infections with certain pairs of Rous sarcoma virus (RSV) and avian leukosis viruses (RAV) give rise to stable combination forms which carry the host range marker of the leukosis virus and the transformation marker of RSV. These agents may be regarded either as avian leukosis viruses which have acquired the ability to transform, or as RSV which has exchanged its host range marker for that of a leukosis virus. The reciprocal combination form would be an avian leukosis virus with the host range of RSV. The evidence presented against phenotypic mixing is not conclusive, even though the absence of excess RAV from recombinant clones was repeatedly confirmed.

- 3053 HYBRIDIZATION OF BURKITT LYMPHOBLASTOID CELLS. (E.) Glaser, R. (Milton S. Hershey Med. Ctr., Pennsylvania St. U., Hershey) and F. J. O'Neill. *Science* 176(4040):1245-1247, 1972.

Burkitt lymphoblastoid cell lines EB₃ (containing Epstein-Barr virus (EBV) antigens in 1-4% of the cells) and P3J-HR1 (containing EBV antigens in <10% of the

cells) were fused to mouse LM(TK⁻) CLID cells and human sternal marrow D98/AH-2 cells, resp., with the use of inactivated Sendai virus. Clones from both hybrids (EB₂/CLID and D98/HRL) were able to grow in selective medium (Eagle's or F-12 supplemented with fetal calf serum, hypoxanthine, aminopterin and thymidine) although both the parental mouse and human marrow lines could not. Analysis of metaphases for each hybrid line showed a modal number of 52 to 53 for EB₂/CLID cells and 100 to 108 for D98/HRL cells; these values confirm that the lines are hybrids. Although indirect immunofluorescence studies were unable to detect EBV antigens in either hybrid line, initial observations revealed that 5'-iododeoxyuridine could induce the synthesis of EBV antigens. No virus particles were found in the cells by electron microscopy.

054 THE OCCURRENCE OF SV40-NEUTRALIZING ANTIBODIES IN SERA OF PATIENTS WITH GENITOURINARY CARCINOMA. (E.) Shah, K. V. (Johns Hopkins U., Sch. Hyg. Public Hlth., Baltimore, Md.), L. D. Palma and J. P. Murphy. *J Surg Oncol* 3(4):443-450, 1971.

Neutralizing antibodies to SV40 were detected in sera from seven of 182 patients studied at the Roswell Park Memorial Institute. Four of 91 (4.4%) bladder tumor patients, two of 24 (8.3%) patients with prostatic carcinoma, and one of four patients with testicular tumors had antibodies. Neutralizing antibodies were demonstrable in repeated bleedings over a 5 to 1 month period. Antibodies against SV40 T-antigen were not detected in any of the sera. None of the antibody-positive patients gave a history of immunization with polio-virus vaccines (a source of major human exposure to SV40 in the U.S. due to contamination). These findings suggest that the seven antibody-positive donors were infected with a virus cross-reacting with SV40 or that infection with SV40 may have occurred in some unknown manner.

055 MUTATION CAUSING TEMPERATURE-SENSITIVE EXPRESSION OF CELL TRANSFORMATION BY A TUMOR VIRUS. (E.) Renger, H. C. (New York U. Sch. Med., N.Y.) and C. Basilio. *Proc Nat Acad Sci* 69(1):109-114, 1972.

Several SV-40 transformed mouse 3T3 cell lines were isolated and characterized according to temperature sensitivity and *in vitro* growth characteristics. All transformant characteristics were expressed at 22°C but not at 39°C. Transformed lines grew at 22°C but not at 39°C as multilayers, reached higher saturation densities, had higher cloning efficiencies and grew faster in gamma-globulin-free medium than did transformants at 39°C. T-antigen synthesis occurred in all transformed lines at either temperature. Confluent transformed cells continued to incorporate ³H-thymidine at 32°C but not at 39°C. Inhibition of DNA synthesis at the higher temperature could be reversed by transferring the cultures to the lower temperature. No significant change in chromo-

some number was noted in the temperature-sensitive transformants. Viruses rescued from all infected lines did not differ in growth characteristics or in transforming ability. It thus appeared that the mutants described were host-cell rather than virus mutants.

3056 VIRUS-LIKE PARTICLES IN HUMAN BREAST CANCER AND CHRONIC CYSTIC MASTITIS. (Ger.)

Thomssen, R. (Inst. Hyg., Gottingen U., Germany), G. Bandlow and P. Stankovic. *Deut Med Wochenschr* 97(7):219-221, 1972.

Electron microscope examination of nine human breast carcinomas and of biopsy material from two cases of chronic cystic mastopathy revealed the presence of pleomorphic virus-like particles in four of the nine breast tumors and in both cases of cystic mastopathy. These particles (average size 110 mμ) with knobby spikes of membrane had a strong structural resemblance to type B particles found in mammary carcinomas of mice, milk from tumor-bearing mice, and some human milk. Inoculation of the material into embryonated chick eggs and monkey kidney tissue cultures gave negative results.

3057 STRUCTURAL STUDIES ON THE ADENOVIRUS

HEXON. (E.) Franklin, R. M. (Public Hlth. Res. Inst. City New York, N.Y.), S. C. Harrison, U. Pettersson, L. Philipson, C. I. Branden and P.-E. Werner. *Cold Spring Harbor Symp Quant Biol* 36:503-510, 1971.

Physical and chemical properties of the adenovirus type 2 (Ad-2) hexon, the major morphological unit of the virus particle, were studied. The molecular wt of the hexon was estimated by sedimentation and diffusion, sedimentation equilibrium, and by crystallographic parameters to be between 313,000 and 396,000. Analysis of tryptic peptides indicated that the hexon was composed of six identical polypeptides of molecular wt 50,000 to 65,000 daltons. X-ray analysis of crystallized Ad-2 hexon suggested that there were four hexons per unit cell and that each hexon was composed of three asymmetric units. Therefore, the hexon probably had threefold symmetry, and the hexon cylinder axis was concluded to be located along the cube body diagonals. Three-dimensional data collected by photographic methods at 10 Å resolution showed no evidence for a non-crystallographic dyad parallel to the threefold axis. Ultrastructural studies on groups of nine hexons suggested that the hexon must be a polar oligomer and emphasized that the perpendicular dyad of the hexon must be interpreted with caution. Therefore, it could not be concluded that the hexon possessed strict D₃ symmetry.

3058 REVERSION OF MURINE SARCOMA VIRUS TRANSFORMED MOUSE CELLS: VARIANTS WITHOUT A RESCUABLE SARCOMA VIRUS. (E.) Fischinger, P. J. (Natl. Cancer

Inst., Bethesda, Md.), S. Nomura, P. T. Peebles, D. K. Haapala and R. H. Bassin. *Science* 176(4038):1033-1035, 1972.

Extended cultivation of single colonies of murine sarcoma virus (MSV)-transformed mouse 3T3 cells ($S^{+}L^{-}$), which were negative for murine leukemia virus (MuLV) and which yielded sarcoma virus after superinfection with MuLV, resulted in the formation of spontaneous flat revertants from which MSV could no longer be rescued. The revertants were able to support MuLV growth and showed an enhanced sensitivity to MSV superinfection. Like normal cells, the flat revertants did not release RNA-dependent DNA polymerase activity into the supernatant fluid, nor did they have any detectable C-type particles. Because revertants could be obtained with high frequency from progeny of single transformed cells, each cell that contained the MSV genome seemed to have the capacity to suppress or eliminate an RNA tumor virus native to its species of origin.

- 3059 RIBONUCLEOTIDE REDUCTASE ACTIVITY OF SYNCHRONIZED KB CELLS INFECTED WITH HERPES SIMPLEX VIRUS. (E.) Cohen, G. H. (Ctr. Oral Hlth. Res., U. Pennsylvania, Philadelphia). *J Virol* 9(3):408-418, 1972.

The rate of DNA synthesis, and activity of ribonucleotide reductase were determined in uninfected and herpes simplex virus (HSV)-infected KB cells synchronized by the double thymidine (TdR) block method. Whereas uninfected cells incorporated ^{14}C -hypoxanthine into DNA only after removal of the TdR block, DNA synthesis in infected KB cells continued whether or not excess TdR was present. CsCl buoyant density centrifugation indicated that excess TdR had no effect on viral DNA synthesis, which accounted for approximately 50% of the incorporation of precursor into acid insoluble material whether or not TdR was present. These results suggest that a normal round of viral DNA synthesis took place under conditions sufficient to inhibit cellular DNA synthesis in uninfected cells. Since relatively more cellular DNA was synthesized in infected TdR-blocked cells, the event which relieved the TdR block was not specific for viral DNA synthesis. Excess TdR also did not inhibit virus replication in infected cells. Assay of TdR blocked uninfected and infected KB cells for ribonucleotide reductase activity showed that enzyme activity was stimulated two-fold by three hr after HSV infection. Reductase activity in extracts from infected cells was less sensitive to inhibition by exogenous TTP than enzyme activity in uninfected cells and functioned at 60% capacity even in the presence of 2 mM TTP. These results support the idea that a viral induced ribonucleotide reductase is present in HSV infected KB cells and that this enzyme is relatively insensitive to inhibition by exogenous TTP.

- 3060 ISOLATION OF SIMIAN VIRUS 40 RECOMBINANTS FROM CELLS INFECTED WITH OLIGOMERIC FORMS OF SIMIAN VIRUS 40 DEOXYRIBONUCLEIC ACID. (E.)

Dubbs, D. R. (Baylor Coll. Med., Houston, Tex.), S. Kit, R. Jaenisch and A. J. Levine. *J Virol* 9(4):717-719, 1972.

Secondary cultures of African green monkey kidney cells (CV-1) were simultaneously infected with two plaque morphology mutants SV40, mKS-U4 (produces fuzzy plaques) and 3T3-4-88J3 (produces clear plaques). The newly synthesized SV40 DNA was isolated, and monomers (A-I), dimers (A-II) and a higher oligomer fraction (trimers-hexamers) (A-III) were purified on alkaline sucrose gradients. These fractions were then assayed for infectivity and plaque morphology. Both small clear- and fuzzy-plaque mutants were obtained from 17-40% of the individual plaques produced by the A-I and A-II fractions, as well as with SV40 DNA monomers or dimers mixed *in vitro*. It is concluded that the cells were probably infected with more than one DNA molecule. Because of the high incidence of mixed plaques after infection with the A-I fraction or from mixed monomers or dimers, a definitive conclusion concerning the origin of SV40 dimers and oligomers was not possible. An unexpected finding was the production of large clear plaques by infection of CV-1 cells with the A-III oligomer fraction. Results suggest that this plaque-type is a stable recombinant and not simply a revertant of the fuzzy- or small-clear-plaque-type virus.

- 3061 HERPESVIRUSES IN TUMORS OF POSTSPAWNING *RANA PIPIENS*. (E.) McKinnell, R. G. (Dept. Zoology, U. Minnesota, Minneapolis) and V. L. Ellis. *Cancer Res* 32:1154-1159, 1972.

Renal adenocarcinomas from six tumor-bearing frogs collected in rural Minnesota during the spring were examined for herpesvirus by electron microscopy. All six renal tumors of *R. pipiens* contained mature herpesvirus 42 days after spawning. Sloughed, lytic tumor cells seen in the lumina of tumor tubules contained viruses in various stages of maturation. Tumor cells showed no virus particles, and this suggested that the tumors were in transition from a stage of active virus production (winter or algid type) to a stage of no virus production (summer or calid type). The enhanced susceptibility of eggs and early embryos to tumor induction by virus suggest that active herpesvirus production at this stage of the life cycle may play an etiological role.

- 3062 PRODUCTION OF INFECTIVE EPSTEIN-BARR VIRUS IN A BURKITT LYMPHOMA CELL LINE, P3HR-1. (E.) Nagoya, T. (Kumamoto U. Med. Sch., Japan) and Y. Hinuma. *Gann* 63(1):87-93, 1972.

Production of infective Epstein-Barr virus (EB) virus in the culture medium of a Burkitt lymphoma cell line, P3HR-1, was examined. Infectivity of the EB virus produced in the P3HR-1 cultures was determined by measuring synthesis of a new non-virion antigen (N-antigen) in a clonal line (C-6) of human hemato-

oietic cells. The percentage of N-antigen-forming cells, detected by an indirect immunofluorescence method, was proportional to the inoculated dose of virus. The quantity of infective EB virus produced by 3HR-1 cells was greater at 33 C than at 37 C. The mounts produced were also higher in low density than in high density cultures. The yield of infective virus from P3HR-1 cultures was proportional to the number of virion antigen-bearing cells in the culture. Infectivity of EB virus was most stable with storage at -80 C. Infectivity was relatively stable at 4 C and was poor at -20, 33 and 37 C. Infectivity decayed most rapidly at 37 C with a half-life of about three days.

063 ANALYSIS OF SIMIAN VIRUS 40-INDUCED TRANSFORMATION OF HAMSTER KIDNEY TISSUE *IN VITRO*: III. INDUCTION OF INFECTIOUS SIMIAN VIRUS 40 FROM VIROGENIC TRANSFORMED HAMSTER CELLS BY AMINO ACID DEPRIVATION OR CYCLOHEXIMIDE TREATMENT. (E.) Kaplan, J. C. (Harvard Med. Sch., Boston, Mass.), J. M. Wilbert and P. H. Black. *J Virol* 9(3):448-453, 1972.

Clones of virogenic SV-40-transformed hamster kidney cells (T8-AP1) were grown for varying lengths of time in medium deficient in the essential amino acids, leucine, arginine or methionine. Infectious virus, determined by plaque assay, was induced after deprivation periods of from 24 to 32 hr. The highest yields of infectious virus were obtained from cultures derived for three to four days. Infectious virus could also be induced by treatment of cell monolayers with cycloheximide. Maximum virus yields were obtained with exposure for 16 and 24 hr periods at 10 µg/ml. Under these conditions, protein synthesis and DNA synthesis were inhibited from 77 to 85% and 70 to 92%, respectively, as determined by the rate of incorporation of radiolabeled precursors. It is suggested that inhibition of protein synthesis by either amino acid deprivation or by cycloheximide is responsible for the induction of infectious SV40 from virogenic cells. It is postulated that the inhibition of protein synthesis produced virus induction by causing a temporary inhibition of DNA synthesis.

064 CO-INFECTION OF MOUSE SPLEEN CELLS WITH MURINE SARCOMA VIRUS AND GUAROA VIRUS. (E.) Woods, W. A. (Natl. Cancer Inst., Bethesda, Md.), W. Turner and M. A. Chirigos. *Appl Microbiol* 3(2):372-376, 1972.

Enhancement of tumor induction by oncornaviruses through a dual viral infection has been described by several investigators. The mechanism of this enhancement was investigated. Spleen cell cultures, derived from BALB/c mice inoculated with murine sarcoma virus-Moloney strain (MSV-M) 7-21 days prior to culture, were inoculated with the Bunyawera group virus, Guaroa virus (GV). The progeny viruses were titrated in both Vero and secondary mouse embryo cells. In mouse embryo cells, low dilutions of the

tissue culture fluid from GV-infected MSV-M spleen cultures produced progressive lytic cytopathic effects. Higher dilutions produced typical MSV-M foci. In contrast, parental GV inefficiently and erratically produced lysis in mouse embryo cells, and parental MSV-M produced only typical foci of transformed cells. The focus-forming titer was higher in dually infected cultures than in control MSV-M-infected cultures. The lytic effect was neutralized only by a mixture of GV and MSV-M antisera; the foci were neutralized only by anti-MSV-M. Progeny of dually infected cultures initially produced only the large parental GV plaque type on Vero cells; however, after seven days, co-infected cultures also contained virus producing minute plaques. Both plaque types were neutralized only by anti-GV serum. It is concluded that GV was at least phenotypically modified by passage in spleen cells co-infected with MSV-M. Further, MSV-M production was stimulated by co-infection with GV.

3065 STUDIES ON MURINE SARCOMA VIRUS: III. SYNTHESIS OF THE VIRAL ANTIGENS IN CELLS OF VARIOUS SPECIES. (E.) Chuat, J. C. (Saint-Louis Hosp, Paris, France), C. Bernard, F. Lasquellec, P. Tchen and M. Boiron. *Proc Soc Exp Biol Med* 139(3):1071-1077, 1972.

The synthesis of murine tumor virus group-specific (GS) and virus envelope (V) antigens following infection of mouse, rat, hamster, chicken, and human cells with mouse sarcoma virus, Moloney strain, was studied by immunofluorescence. The two antigens were detected in mouse embryo cells as early as 12-15 hr post-infection (PI) reaching maximal levels at 24-48 hr. An early cytopathic effect (CPE) involving the whole monolayer was consistently present after 24 hr, although only a fraction of the cells were actively synthesizing viral antigens at this time. Identical results, except for cellular alterations, were obtained after infection of rat embryo cells. Chicken and hamster cells remained totally negative with respect to GS and V antigens. Infection of human diploid cell lines resulted in the appearance of murine GS and V antigens and CPE ten days PI. The proportion of antigen-containing cells were observed to decrease in consecutive subcultures.

3066 INDUCTION OF MALIGNANT MELANOMAS ASSOCIATED WITH FIBROSARCOMAS IN GNOTOBIOTIC CATS INOCULATED WITH GARDNER-FELINE FIBROSARCOMA VIRUS. (E.) McCullough, B. (Dept. Vet. Path., Ohio St. U., Columbus), J. Schaller, J. A. Shaddock and D. S. Yohn. *J Nat Cancer Inst* 48(6):1893-1896, 1972.

Gnotobiotic kittens were injected i.m. or s.c. as neonates with concentrated preparations of the Gardner strain of feline fibrosarcoma virus (G-FeSV) propagated in tissue culture. Palpable tumors developed at the site of injection within 21-45 days (s.c.) or 90 days (i.m.). All tumors became pigmented within six wk after their initial appearance. Tumors

invaded the intercostal muscles, diaphragm, pericardium, and mediastinum or metastasized to skin and regional lymph nodes of some animals. Histologically, the primary neoplasms were composed of melanocytic and fibroblastic elements. Neoplastic cells were concentrated within the dermis but extended into the epidermis and subcutis. The metastatic skin nodules appeared similar to the primary tumors, whereas the noncutaneous metastases appeared similar to the fibroblastic areas. All five tumor homogenates tested contained detectable titers of gs-3 antigen.

- 3067 RELATIONSHIP BETWEEN ORGANIZATION OF MAMMARY TUMORS AND THE ABILITY OF TUMOR CELLS TO REPLICATE MAMMARY TUMOR VIRUS AND TO RECOGNIZE GROWTH-INHIBITORY CONTACT SIGNALS *IN VITRO*. (E.) McGrath, C. M. (Dept. Zoology, U. California, Berkeley), S. Nandi and L. Young. *J Virol* 9(2):367-376, 1972.

The relationship between mouse mammary tumor organization, organization of cultured mammary tumor cells, and replication of mammary tumor virus (MTV) was studied. MTV replication, shown by electron microscopic techniques, was confined primarily to cells organized as acini in intact mouse mammary glands. Primary mammary tumors maintained a high degree of acinar organization and cells therein continued to replicate MTV. Nonacinar mammary cells, derived by serial transplantation of acinar cells, no longer actively replicated MTV. This suggests that phenotypic differences exist among mammary epithelial cells in their ability to support virus replication, that a fundamental relationship exists between the organization of epithelium for secretion and active virus replication, and that this relationship is not altered as a primary consequence of neoplastic transformation. Mammary epithelial cells from pregnant, nontumor-bearing MTV-infected BALB/cfc3H mice, or from acinar mammary tumors from a number of mouse strains grown in culture under the influence of insulin or cortisol exhibited the ability to organize into discrete three-dimensional structures called "domes". MTV replication, determined by radioassay and indirect immunofluorescence, took place primarily in cells within these domes. Cells cultured from nonacinar tumors did not tend to organize into domes nor did they replicate MTV in primary culture. These results suggest that the cell organizational requirement for MTV replication observed *in vivo* is conserved in primary culture. Dome formation was not a result of virus replication, as uninfected BALB/c cells formed domes without MTV replication. Contact-dependent growth-regulatory signals (estimated from the saturation density of the culture) in non-MTV infected mammary epithelium cultures were not altered by virus active replication nor as a direct consequence of neoplastic transformation. Cells derived from nontumor BALB/cfc3H glands and from spontaneous tumors exhibited cell growth kinetics, saturation densities and DNA synthesis rates nearly identical to those of noninfected normal mammary epithelium in primary culture. Cultured nonalveolar tumor cells grew to higher-than-normal cell densities indicating altered growth regulatory signals.

- 3068 TRANSLATION OF AVIAN MYELOBLASTOSIS VIRUS RNA IN A CELL-FREE LYSATE OF *ESCHERICHIA COLI*. (E.) Siegert, W. (Max-Planck-Inst. Biochem., Munich, W. Germany), R. N. H. Konings, H. Bauer and P. H. Hofschneider. *Proc Nat Acad Sci USA* 69(4):888-891, 1972.

The messenger functions of purified avian myeloblastosis virus (AMV) RNA were examined in a cell-free system using an extract of *E. coli*. AMV-RNA stimulated ^{14}C -labeled amino acid incorporation into acid insoluble material to an extent ranging up to 20% of the incorporation obtained under the direction of homologous phage M12 messenger RNA. Polyacrylamide gel electrophoresis and double immunodiffusion in agar gel, combined with autoradiography, showed that one AMV-RNA directed protein was antigenically identical to the group-specific antigen 4, and that three other proteins corresponded in molecular wt to group-specific antigens 1-3.

- 3069 RAT C-TYPE VIRUS (BV-1): EFFECT OF AMNIOTIC FLUID, FETAL SERUM, AND HORMONES IN CELL CULTURE. (E.) Bergs, V. V. (U. Miami Sch. Med., Florida). *Proc Soc Exp Biol Med* 140(1):102-105, 1972.

The possible effects of bovine amniotic fluid (BAF), fetal calf serum (FCS), estrogen, and progesterone on the growth and cytopathic effect (CPE) of BV-1, a C-type virus isolated from a DMBA-induced rat mammary carcinoma, was studied in Wistar-Furth rat embryo cell cultures. BAF (30%) and FCS (10%) protected rat cell cultures from BV-1-induced CPE. Whereas the entire cell sheet of infected control cultures showed CPE by day 7-10, only 50% of the cells in cultures treated with BAF or FCS were affected. At the same time, higher titers of infectious BV-1 were produced as early as two days post-infection in cultures maintained on medium supplemented with BAF or FCS as compared to cultures on medium supplemented with newborn calf serum. A similar stimulatory effect on the growth of BV-1 in these cultures was exerted by 95% natural estrogen. The effect was dose-dependent with concentrations between 1.0 and 2.5 $\mu\text{g/ml}$ being the most effective. Progesterone had no stimulatory effect on the replication of BV-1 and appeared to be suppressive at higher dose levels.

- 3070 A TRANSPLANTABLE LEUKEMIA FROM MICE INOCULATED WITH RAUSCHER LEUKEMIA VIRUS. (E.) Fredrickson, T. N. (Dept. Animal Dis., U. Connecticut, Storrs), J. LoBue, P. A. Alexander, Jr., E. F. Schultz and A. S. Gordon. *J Nat Cancer Inst* 48(6):1597-1605, 1972.

Rauscher leukemia virus (RLV) was given in serial log dilutions from undiluted to 10^{-8} , either i.p. or i.m., to male and female newborn and weanling BALB/c mice. Extremely high dilutions (10^{-1} or undiluted virus), given i.p., caused early mortality and splenic destruction. Relatively high dilutions (10^{-2} and 10^{-3} i.m. and 10^{-3} i.p.) of RLV induced chronic leukemia in

reated mice, which were characterized by wasting, anemia, large numbers of erythroid and/or myeloid precursors in the peripheral blood, splenomegaly and hepatomegaly. There was no lymphoproliferative involvement of the lymph nodes, thymus, or splenic white pulp. Thus induction of myelogenous leukemia appears to be part of the oncogenic spectrum of RLV. Successful isogenic transplantation of leukemic cells in four series by i.v. inoculation of recipients illustrated the truly neoplastic nature of the chronic disease. Plasma derived from mice bearing the transplantable leukemia induced a chronic disease in BALB/c mice involving erythroid precursors.

71 FBJ VIRUS-INDUCED TUMOURS IN MICE: A HISTOPATHOLOGICAL STUDY OF FBJ VIRUS TUMOURS AND THEIR RELEVANCE TO MURINE AND HUMAN OSTEOSARCOMA ARISING IN BONE. (E.) Price, C. H. G. (U. Bristol, England), M. Moore and D. B. Jones. *Brit J Cancer* 26(1):15-27, 1972.

born inbred CBAT6T6 mice were either injected i.m. with an FBJ virus-containing Moloney procedure concentrate from a CFI mouse osteosarcoma, or were injected i.p. with a cell-free extract prepared from transplant of the osteosarcoma (FBJ7). Nine of the mice injected i.m. and five of seven mice injected i.p. developed tumors. Tumors in i.m.-injected mice appeared between 27 and 48 days after inoculation and were located at or near the injection site. Tumors in i.p.-injected mice had relatively longer latent periods and were found in the regions of the lumbar spine, ribs, and sternum, and occasionally consisted of more than one discrete nodule. All tumors grew progressively on s.c. implantation in syngeneic hosts with slow invasion of surrounding soft tissue and muscle, but no metastases were seen. Twelve primary and first generation transplants were examined microscopically. Except for two periosteal fibro-spindle-cell sarcomata and two other tumors, all lesions were similar showing a loosely textured pattern of scattered pleomorphic cells. A few tumors contained areas where hyaline matrix suggested ill-formed primitive cartilage or chondrosteoid, but the related cells retained their undifferentiated appearance. In several tumors tiny islets of well-formed mature large cartilage were found. Some foci were undergoing ossification. However, no tumors showed convincing evidence that the cells were able to produce osteoid directly, and all matrix other than collagen appeared to be due to metaplasia or maturation. Thus, in definition, no tumor was acceptable as a conventional osteosarcoma. The FBJ fibrosarcomata differed on several criteria from spontaneous and Sr90-induced murine osteosarcomas and from human osteosarcomas.

72 SEPARATION OF TWO TYPES OF ADENO-ASSOCIATED VIRUS PARTICLES CONTAINING COMPLEMENTARY DEOXYNUCLEOTIDE CHAINS. (E.) Berns, K. I. (Johns Hopkins U. Sch. Med., Baltimore, Md.) and S. Adler. *Virology* 9(2):394-396, 1972.

Adeno-associated virus (AAV2H) DNA from virus grown in KB cells coinfecting with adenovirus type 2 as helper was radiolabeled with ^{32}P and density labeled with BUDR. Purified ^{32}P -BUDR-substituted AAV was fractionated by CsCl equilibrium centrifugation. Two classes of AAV particles differing in density by 6 mg/cm³ were isolated. Buoyant density centrifugation of purified DNA from the light and heavy bands showed that 80% of the particles in the heavy virus preparation contained the heavy single DNA strand and 75 to 90% of the DNA from the light particle preparation was of the light single-strand type.

3073 COMPARISON OF SOME REACTIONS CATALYZED BY DEOXYRIBONUCLEIC ACID POLYMERASE FROM AVIAN MYELOBLASTOSIS VIRUS, *ESCHERICHIA COLI*, AND *MICROCOCOCCUS LUTEUS*. (E.) Wells, R. D. (Coll. Agric. Life Sci., U. Wisconsin, Madison), R. M. Flügel, J. E. Larson, P. F. Schendel and R. W. Sweet. *Biochemistry* 11(4):621-629, 1972.

A comparative study was performed on the template specificities of the highly purified DNA polymerases from *Escherichia coli* and *Micrococcus luteus* and of a partially purified DNA polymerase from virions of avian myeloblastosis virus (AMV). The three DNA polymerases show approximately the same capacity to utilize twenty different high molecular weight templates. Thus, when tested with polymer templates (primers), the two bacterial DNA polymerases are at least as effective "reverse transcriptases" as the tumor virus associated DNA polymerase. However, (rA)_n·oligo(dT) is a markedly better template than (dA)_n·oligo(dT) for the AMV DNA polymerase, as reported previously. For the *M. luteus* DNA polymerase, the two templates are approximately equally effective. The AMV DNA polymerase provides faithful DNA synthesis when either DNAs or RNAs serve as templates (primers). DNA synthesis is dependent on the presence of a suitable primer strand and the newly synthesized DNA strand is covalently attached to the primer strand through a phosphodiester linkage. Thus, when a polyribonucleotide serves as a primer, the new DNA strand is joined to an RNA molecule. The AMV DNA polymerase apparently cannot initiate the synthesis of a new DNA strand. This behavior is identical with that observed for the two bacterial DNA polymerases.

3074 HYBRIDIZATION CHARACTERISTICS OF COMPLEMENTARY RNAs GENERATED ON MURINE MYELOMA DNA TEMPLATES. (E.) Gottlieb, A. A. (Inst. Microbiol., Rutgers U., New Brunswick, N.J.) and D. N. Tenney. *J Nat Cancer Inst* 48(5):1457-1462, 1972.

Complementary RNAs (c-RNAs) to DNA templates were produced by addition of *E. coli* sigma-containing RNA polymerase to native MAK-purified DNA templates from murine myelomas MOPC-21 and Adj-PC-5. c-RNAs were then annealed to each tumor DNA template at a temperature 16.5 C below the melting temperature of the tumor

DNAs. Under these conditions, specific hybrids were formed which had a high cytosine-guanine and a low adenine-thymine content and which had a sharp melting point. The percentage of each myeloma DNA annealed with c-RNA from the Adj-PC-5 or MOPC-21 tumors at saturation was essentially similar. c-RNA from either tumor could discriminate between tumor DNA, mouse liver DNA, and calf-thymus DNA. Although a number of the mouse liver DNA sequences were probably represented in both tumor DNAs, neither of the tumor DNAs exhibited preferential binding to mouse liver c-RNA. These observations were also supported by results of experiments in which unlabeled c-RNAs derived from each DNA were used in reciprocal competition experiments with prelabeled c-RNAs generated on these templates.

- 3075 COMPONENT OF STRAIN MC29 AVIAN LEUKOSIS VIRUS WITH THE PROPERTY OF DEFECTIVENESS. (E.) Ishizaki, R. (Duke U. Med Ctr., Durham, North Carolina), A. J. Langlois, J. Chabot and J. W. Beard. *J Virol* 8(6):821-827, 1971.

Three clones of morphologically altered cells (L-MC29) of singular properties were isolated from MC29 (subgroup A) leukosis virus-infected chick embryo cells. Supernatant fluids from cultures of the cloned cells produced no transforming or interfering activity on chick embryo cells susceptible to known avian leukosis-sarcoma viruses. No virus associated with the cells was demonstrable by fluorescent-antibody staining or by electron microscopy. All L-MC29 clone cells were activated, however, by four strains of Rous-associated viruses (RAV) representative of A, B, C, and D subgroup avian leukosis viruses and by two strains of MC29 virus. Virus L-MC29 cells activated by superinfection with RAV-1 and RAV-2 were characterized by helper-dependent and helper-independent properties. These findings suggest that the strain MC29 leukosis virus, or a component thereof, possessed properties of defectiveness similar to those of the Bryan high-titer Rous sarcoma virus.

- 3076 CLONAL ASPECTS OF THE C-TYPE VIRUS RELEASING CELLS OF A CULTURED HUMAN RHABDOMYOSARCOMA LINE (RD 114) *IN VITRO*. (E.) Nelson-Rees, W. A. (U. California, Sch. Public Hlth., Oakland), R. M. McAllister and M. B. Gardner. *Nature New Biol* 236 (66):147-149, 1972.

Chromosome studies were conducted on the RD114 rhabdomyosarcoma line which was formed by the direct outgrowth of cells from a solitary tumor taken from the cerebellum of a kitten which had been inoculated *in utero* with cultured human rhabdomyosarcoma cells (RD line no. 2). This tumor and the RD114 cell line derived from it contained C-type particles. Metaphase cells from the RD114 cell line contained a small ring marker chromosome which was present in 78% of passage 21 cells, in 72% of passage three, and in 10% of the parental RD no. 2 cells used in the original inoculum. It was felt that some of the chromosome fragments observed

in early passage of RD no. 2 cells were actually the ring marker chromosome. It was also felt that this chromosome may have arisen as a result of X-irradiation of the patient prior to the biopsy used to initiate the RD no. 2 line, as the RD no. 1 line, initiated prior to radiation treatment, did not contain it. The blood-brain barrier, the "immunologically privileged" position of the brain and the corresponding fact that brain metastases are rare suggested that the formation of the kitten brain tumor was initiated by a single cell or a small number of chromosomally similar cells.

- 3077 FURTHER CHARACTERIZATION OF LIVER CATALASE-DEPRESSING FACTOR FROM SPLEENS OF FRIEND VIRUS-INFECTED GERM-FREE AND CONVENTIONAL MICE. (E.) Price, F. W. (Dept. Biol., St. U. Coll., Buffalo, N.Y.) and E. A. Mirand. *J Surg Oncol* 3(1):17-23, 1971.

The activity of a liver catalase-depressing factor (LCDF) extracted from spleen was studied in Friend virus-infected male Ha/ICR Swiss mice. The spleen extracts were assayed *in vitro* for LCDF using a liver homogenate from healthy mice as a source of enzyme. Mice were splenectomized on the seventh day postinfection and the subsequent effect on liver catalase activity was determined. Whereas the liver catalase activity of splenectomized infected mice returned to near-normal values about two wk after removal of the spleens, the mean liver catalase activity of the nonsplenectomized FV-infected groups was consistently lower than that of the corresponding healthy group. These results were considered as further evidence indicating that the lowered liver catalase activity in infected mice was due to a spleen-elaborated humoral factor (LCDF). I.p. injection of 10 mg LCDF into germ-free and conventional mice significantly depressed ($P < 0.001$) liver catalase activity below that of control mice after 48 hr. I.p. injection of 20 mg LCDF significantly decreased ($P < 0.001$) the mean thymus wt of healthy mice compared with normal controls. LCDF preparations extracted from conventional and germ-free Ha/ICR Swiss mice exerted no inhibitory effect on the catalase activity of a mouse liver homogenate. In these respects, LCDF was sharply differentiated from miscellaneous anti-catalases and was shown to be a true toxohormone.

- 3078 CULTIVATION OF THE SOFT PERITONEAL TISSUES INOCULATED WITH HUMAN ADENOVIRUS TYPE 12 *IN VIVO*. (E.) Motoi, M. (Okayama U. Med. Sch., Japan). *J Karyopathol* 13(3):131-138, 1971.

Adenovirus type 12, prototype strain "Huie", was inoculated i.p. into Syrian golden hamsters at birth. Twenty-four hr after virus inoculation, the peritoneal tissues were excised and cultured *in vitro*. By six to seven wk growth, two of four cultures showed the presence of morphologically transformed foci consisting of rapidly proliferating

small epithelioid cells which tended to pile up. Transformed cells contained a round nucleus with one or three nucleoli and scanty cytoplasm. Giant cell formation was seen frequently. Six hamsters were inoculated i.p. with 5×10^6 transformed cells and all animals subsequently developed multiple abdominal tumors and bloody ascites. Histologically, the tumors resembled the primary virus-induced tumor. Inoculation of transformed cells to virus sensitive fetal human kidney cells failed to demonstrate the presence of infectious virus. The supernatant fraction from tumor homogenates which had developed from transformed cells gave positive complement fixation reactions with serum of Ad-12-tumor bearing hamsters.

- 79 COMPARATIVE STUDY OF THE EFFECT OF EQUINE HERPES 3 VIRUS AND HERPES SIMPLEX VIRUS ON CHROMOSOMES OF RABBIT KIDNEY CELLS. (E.) Samso, (Dept. Med., U. Cambridge, England) and A. Karpas. *J. Bakt (Orig)* 218:417-433, 1971.

Primary rabbit kidney (RK) cell monolayers were infected separately with equine herpes 3 virus (EH3V) and with herpes simplex virus (HSV). At regular time intervals, viral infected and uninfected cells were arrested at metaphase with colchicine and prepared for karyotype analysis. Chromosomal lesions could be detected as early as four hr post infection, and it was noted that the same type of lesions were induced by both EH3V and HSV infected RK cells. The lesions consisted of chromosomal gaps, rearrangements, breaks, and lysis. A higher percentage of HSV-infected cells exhibited lesions which were more severe when compared to EH3V-infected cells. During the incubation period, there was an increase in the percentage of affected mitoses in both EH3V- and HSV-infected cells, but the increase was greater in HSV-infected cells. It is concluded that since the generation time of HSV was shorter than that of EH3V, the degree of chromosomal aberrations induced in RK cells is associated with a shorter virus generation time.

- 80 TRANSFORMATION OF FISCHER RAT EMBRYO CELLS BY THE COMBINED ACTION OF MURINE LEUKEMIA VIRUS AND (-)-TRANS- Δ^9 -TETRAHYDROCANNABINOL. (E.) P. J. (Microbiol. Assoc., Inc., Bethesda, Md.), W. A. Suk, G. J. Spahn and A. E. Freeman. *J. Soc Exp Biol Med* 140(2):454-456, 1972.

High passage Fischer rat embryo cells (F1706) were inoculated with Rauscher leukemia virus (RLV). After three subcultures, the infected cells were treated with $1.0 \mu\text{g/ml}$ of either (-)-trans- Δ^8 -tetrahydrocannabinol ($\Delta^8\text{THC}$), trans-cannabidiol (CBD), $\Delta^9\text{THC}$ or cannabiniol (CBN). Cells were fed chemical every day for six days and were then passaged serially in the absence of chemical. Cultures were checked at intervals for the presence of transformed cells. None of the cannabinoids studied caused any visible cell transformation after six subdivisions and were therefore considered not to be transforming

agents. Control cultures treated with 3-methylcholanthrene showed transformation after three subdivisions. Cultures treated with both concentrations of $\Delta^9\text{THC}$, however, showed macroscopic transformed foci after the 13th subculture. Cultures treated with virus alone or with $\Delta^8\text{THC}$, CBN or CBD showed no transformed foci after 20 subcultures. Inoculation of newborn Fischer rats with cells from cultures started from the 3-MC and $\Delta^9\text{THC}$ transformed foci resulted in the appearance of sarcomas at the site of injection after five days in all treated rats. No tumors developed in rats 90 days after inoculation with cells from control RLV-infected cultures.

- 3081 DETECTION OF AVIAN MYELOBLASTOSIS VIRUS IN CHICK FIBROBLAST CULTURES WHICH HAD BEEN TREATED WITH DNA FROM VIRUS-PRODUCING LEUKEMIC CELLS. (Fr.) Lacour, F. (Gustave-Roussy Inst. Villejuif, France), A. Fourcade, E. Merlin and Th. Huynh. *C R Acad Sci [D] (Paris)* 274(15):2253-2255, 1972.

A culture of chick fibroblasts was inoculated with a DNA extract from leukemic cells producing an avian myeloblastosis virus (AMV) and with DEAE dextran; the supernatant liquid injected to chicks induced typical myeloblastic leukemia. In two out of three cultures ultramicroscopic examination after two wk revealed the presence of mature virus particles in extracellular spaces or burgeoning forms in the cellular membrane only in cultures inoculated simultaneously with a DNA extract from myeloblastic cells and with DEAE dextran. The virus particles were of the C type and were identical with those belonging to the avian leukemic-sarcoma group. The cells showed no sign of malignant transformation. Chicks inoculated with supernatant liquid from the above culture developed myeloblastic leukemia identical with that produced by AMV. Leukemic cells produced a virus with ATPase activity characteristic of AMV. In contrast, no virus production occurred in cultures inoculated with the DNA extract from leukemic cells or with DEAE dextran alone. These results appear to support Temin's hypothesis which postulates that at least part of the oncogenic information is contained in DNA of transformed cells.

- 3082 ELECTRON MICROSCOPICAL STUDY OF ROWSON-PARR VIRUS INFECTION IN BALB/c MICE. (E.) Michaels, L. (Inst. Laryngology Otology, London, England), K. E. K. Rowson and E. S. Bird. *Int J Cancer* 9(1):162-171, 1972.

The significant electron microscopic changes during the course of Rowson-Parr virus (RPV) infection in young adult female BALB/c mice are described. RPV has previously been shown to induce splenomegaly and, later, lymphatic leukemia in infected mice. Splenomegaly occurred in these experiments from 13 to 28 days after RPV infection. During this period, there was active folding of cell membranes of reticulum cells of the spleen in germinal centers and red pulp. In some spleens at this stage virus-like structures

similar to mature C-type oncogenic RNA virus were observed extracellularly only, but in close association with folded cytoplasmic membranes. Budding of virus particles from the cytoplasmic membrane of reticulum cells or any other splenic cells could not be seen at this stage. Cell membrane folding was interpreted as the localization of virus antigen prior to specific antibody production. Beginning on the 25th day, spleens showed numerous plasma cells in the red pulp. These changes persist to a lesser degree in the spleen throughout the period when it is of normal size. The cells constituting the lymphoma resembled those of other murine virus induced lymphomas and had numerous C-type particles budding from their membranes. Electron microscopy of negatively stained centrifuged plasma showed the presence of scattered virus particles of typical murine oncogenic type during the first four days. Beginning on the fifth day, the virus particles became agglutinated into groups suggesting the presence of an immune response. Perivascular mononuclear cell infiltrates composed of plasma cells and reticulum cells with folded membranes, enclosing virus particles, were seen in the kidneys after the 30th wk. RPV infection thus caused a prolonged immunological response to the virus with subsequent tumor development at the site of the response. This was consistent with the idea that intense and prolonged antigenic stimulation is possibly a cause of neoplasia.

- 3083 DIFFERENCES IN THERMAL STABILITY OF DEOXYTHYMIDINE KINASE ACTIVITY IN EXTRACTS FROM CELL INFECTED WITH HERPES SIMPLEX VIRUS TYPE 1 OR TYPE 2. (E.) Ogino, T. (Milton S. Hershey Med. Ctr. Pennsylvania St. U., Hershey) and F. Rapp. *Virology* 46(3):953-955, 1971.

Deoxythymidine (TdR) kinase activities of cells were determined by the rate of phosphorylation of ³H-TdR (38C, 15 min) in cell-free extracts prepared by sonication of confluent cultures of primary rabbit kidney (RK), primary hamster embryo, and human embryonic lung cells infected (one hr, 37° C) with either herpes simplex virus (HSV) type 1 or HSV type 2. TdR kinase activity in type 2-infected RK cells began to increase at 11 hr after infection and reached a maximum activity (60 μmoles nucleotide/15 min) of over 50 times that of uninfected RK cells after 50 hr. In type 1-infected cells, the initial increase in TdR kinase activity occurred seven to eight hr after that observed in type 2-infected cells. Thermal stability of TdR kinase was determined in cell extracts 30 hr after infection with type 1 or type 2 HSV. Extracts were heated at 40° C for ten, 20 or 30 min before assaying for TdR kinase. TdR kinase activity of type 2 infected cells was more heat-labile than that of type 1 infected cells. Only 3% of TdR kinase activity remained in HSV-2 infected cells after ten min of heating, compared to 48% in HSV-1 infected cells. Uninfected TdR kinase activity was the most stable of the three activities tested (95% of TdR kinase activity remaining after ten min). Similar results were obtained for human

embryonic lung, hamster embryo and HDC-17 hamster (HSV-2 transformed) cells.

- 3084 RECENT PROGRESS ACHIEVED IN THE STUDY OF MAREK'S DISEASE OR AVIAN NEUKOLYMPHOMATOSIS. (It.) Zanella, A. (Inst. Inf. Dis. U. Milano, Italy). *Boll Ist Sieroter Milan* 50(4):306-317, 1971.

Inoculation of 1-day-old specific pathogen-free chicks [route not specified] with leukocytes or filtered or unfiltered skin homogenates from chickens with acute Marek's disease (MD) caused death, characteristic lesions of MD, and the production of precipitating antibodies for MD; inoculation of chicks with plasma from the same animals had no effect. When MD virus (LCBS 216/68 strain) was grown in chicken kidney cell monolayers and the cells were passaged, the characteristic cytopathic effect gradually increased in intensity until the 18th passage, after which its intensity decreased. The gel-precipitation reaction showed a gradual decrease in the production of antigen fraction A, starting with the 25th passage; this antigen disappeared completely by the 38th-40th passage, but another antigen fraction was still present in the cell extract. Inoculation of MD virus i.p. and i.m. into 1-day-old chicks showed a progressive decrease in virus pathogenicity which was completely attenuated by the 40th passage. Marek's disease virus was isolated from the blood of these chickens 60 days after inoculation, but not from control animals placed in contact with the inoculated chickens. Vaccination of chicks with this attenuated virus caused a significant decrease in mortality from MD in animals inoculated with a virulent strain 6.5 months after vaccination.

- 3085 ELECTRON MICROSCOPE STUDY OF LABELED LECTIN FIXATION BY RAIFORT'S PEROXIDASE ON HUMAN EMBRYO CELLS, TRANSFORMED *IN VITRO* BY A BRYAN STRAIN OF ROUS SARCOMA VIRUS. (Fr.) Francois, D. (Coll. France, Exp. Med. Lab., Paris, France), V. Van Tuyen, H. Febvre and F. Haguenau. *C R Acad Sci [D] (Paris)* 274(13):1981-1984, 1972.

The bonding of agglutinins, wheat germ lipase extract (WGA) and concanavaline A (Con A) to the surface of human fibroblasts transformed *in vitro* by Rous sarcoma virus (RSV) (strain EH₄R₂) was studied with the electron microscope by using Raifort's peroxidase which can be visualized by oxidation of diaminobenzidine in the presence of hydrogen peroxide. Human fibroblasts transformed by RSV gave a positive reaction at the level of the peripheral membrane with both WGA and Con A. With WGA this was manifested by a dense and continuous precipitate and with Con A, by a discontinuous, less dense precipitate. Without agglutinin no trace of a precipitate was discernible at the surface of the cells. While normal cells treated with Con A gave a positive reaction similar to the peripheral reaction with transformed cells, cells treated with WGA gave no reaction at all. These

sults suggest that there is a close correlation between cellular agglutinability, the ability to x WGA₁ and malignant transformation by an RNA virus. WGA is thus particularly suited for the study of changes in membrane structure caused by ligant transformation.

- 86 DNA OF ROUS SARCOMA VIRUS: ITS NATURE AND SIGNIFICANCE. (E.) Levinson, W. E. Dept. Microbiol., U. California, San Francisco), E. Varmus, A.-C. Garapin and J. M. Bishop. *Science* 175(4017):76-78, 1972.

periments were conducted to determine the source and significance of double-stranded DNA associated with virus of the Schmidt-Ruppin strain of Rous sarcoma virus (RSV). DNA-RNA hybridization followed by 2SO₄ equilibrium centrifugation indicated that the DNA was not a viral RNA transcription product. Successful annealing of virion DNA to avian host cell DNA suggested that viral DNA was probably a product of the host cell DNA. It was concluded that viral DNA is not necessary for biological activity of RSV since extensive substitution of bromodeoxyurine for virus-associated DNA thymidine did not photosensitize the biological activity of the virus.

- 87 EQUINE ABORTION (HERPES) VIRUS-SPECIFIC RNA. (E.) Huang, H. L. (U. Mississippi Sch. of Med., Jackson), J. M. Szabocsik, C. C. Randall and A. Gentry. *Virology* 45(2):381-389, 1971.

The pattern of virus-specific RNA synthesis in mouse cell cultures infected with equine abortion virus (EAV) was studied. Hybridization experiments using purified EAV DNA and ³H-labeled cytoplasmic RNA purified from infected cells showed that virus-specific RNA was largely confined to the polysome fractions. ³H-RNA from control cells failed to bind the viral DNA. Virus specific RNA from polysomal fractions was demonstrated clearly at 2-4 hr post-infection when cellular DNA synthesis was beginning to be shut down; it continued through 12-14 hr post-infection. To test the possibility that virus-specific RNA made after the onset of synthesis of cellular DNA (4-6 hr post-infection) was different from that made early, hybridization competition experiments were conducted. Viral DNA was first hybridized to unlabeled RNA extracted at 4, 8 and 12 hr post-infection, and then was hybridized to ³H-RNA extracted during the intervals 2-4, 6-8 and 10-12 hr after infection. The results indicated that approximately one-third to one-half of the RNA made between 10 and 12 hr post-infection was of a species made early (2-4 hr) after infection. These results were similar to those reported for RNA synthesis patterns in vaccinia virus-infected cells and for T2 bacteriophage.

- 88 ENDONUCLEASE ACTIVITY ASSOCIATED WITH PURIFIED SIMIAN VIRUS 40 VIRIONS. (E.)

Kaplan, J. C. (Harvard Med. Sch., Boston, Mass.), S. M. Wilbert and P. H. Black. *J Virol* 9(5):800-803, 1972.

SV40 virions purified by CsCl density gradient centrifugation were assayed for endonuclease activity by measuring the rate of conversion of ³H-labeled form I (double-stranded, circular) SV40 DNA into a nicked form. The conversion product sedimented as a sharp peak in linear alkaline sucrose gradients indicating that random breakage of form I DNA did not occur. No acid-soluble nucleotides were released during the reaction, showing the absence of exonuclease activity. The reaction was dependent on Mg⁺⁺ ions and was totally inhibited by 0.02 M EDTA or by preheating the purified virus at 80 C for 10 min. Maximum activity occurred between pH 6.7 and pH 7.1. Enzyme activity was proportional to the amount of SV40 protein and was apparently not due to contamination by host cell protein. It was not determined whether the endonuclease produced single- or double-stranded breaks in native SV40 DNA, since both forms had similar sedimentation velocities under these experimental conditions.

- 3089 THE ALTERED PATTERNS OF TRANSFER RNA IN SV40-INFECTED AND TRANSFORMED CELLS. (E.) Sekiya, T. (Inst. Microbial Chem., Tokyo, Japan) and K.-I. Oda. *Virology* 47(1):168-180, 1972.

Transfer RNAs (tRNA) were extracted from cultured African green monkey kidney (AGMK) cells, SV40-transformed AGMK cells (clone T22) and SV40-infected AGMK cells (70 hr post-infection), and their elution profiles from DEAE-Sephadex columns were compared. Among 19 aminoacyl-tRNAs tested, those for aspartic acid (asp-tRNA), asparagine (asn-tRNA) and histidine (his-tRNA) revealed differences between the normal and the transformed or infected cells. All three eluted in two peaks (I and II), but the relative amount of the peak II which was eluted at a higher salt concentration than peak I, was much greater in transformed or infected than in normal cells. In SV40-infected C14 cells (an established cell line of AGMK), an increase in the amounts of the second peak of asp-tRNA and his-tRNA was observed after extensive replication of SV40 DNA. Infection with UV-irradiated SV40 did not cause any significant change in asp-tRNA and his-tRNA. tRNAs from 3T3 and SV40-transformed 3T3 cells (SV3T3) were similarly compared; tRNAs from SV3T3 for leucine, isoleucine, phenylalanine, and threonine contained a new peak which was lacking in the corresponding tRNAs from 3T3 cells. None of the newly appearing species of tRNA could hybridize with SV40 DNA.

- 3090 PARTIALLY DOUBLE-STRANDED RNA IN MOUSE SPLEEN CELLS: THE EFFECT OF INFECTION WITH RAUSCHER VIRUS. (Rus.) Kiselev, F. L. (D. I. Ivanovskii Inst. Virol., Moscow, USSR), L. A. Semenova and I. S. Irlin. *Vop Virusol* 16(4):500-502, 1971.

Findings of a study of specific fractions of RNA in spleen cells of mice infected with Rauscher virus are presented. The virus was injected i.v. after suspension in mouse plasma. This gave 50 transformation foci in spleen cells of BALB/c mice in 1:1000 dilution. The mice were autopsied in various stages of infection, the spleens were homogenized, and RNA was extracted with phenol followed by precipitation with alcohol and 2M NaCl. The resulting high-molecular weight RNA preparation was fractionated on a cellulose column with 15% alcohol. The replicative intermediate form was eluted with buffer consisting of 0.1M NaCl, 0.01M tris-buffer (pH 7.0), and 0.001M ethylenediaminetetraacetic acid sodium salt. The replicative intermediate form was eluted as double-stranded RNA in column fractionation using benzoylated diethylaminoethyl cellulose. The RNA from infected cells had a lower sensitivity to RNase (10 µg/ml, 30 min., 37 C). The RNA fraction eluted from normal cells was 2-4% of the total RNA fractionated. This content increased to 12-14% three days after infection, and then decreased. Synthesis of this RNA fraction was observed in infected cells when mice were injected i.p. with ^{32}P - or ^{14}C -orotic acid. There was a correlation between the amount of virus administered and the quantity of double-stranded RNA. In order to clarify whether synthesis of this fraction depended on virus infection, Rauscher virus and spleens of C57/B1 mice (in which Rauscher virus does not multiply) were used. The RNA fraction increased sharply when the leukemic process was stimulated by a complete Freund's adjuvant after Rauscher virus infection, while Freund's adjuvant alone did not have any effect on synthesis of this RNA fraction. This indicates the virus specificity of the fraction. Thus, Rauscher virus increased synthesis of double-stranded RNA by immunocompetent spleen cells in BALB/c mice.

- 3091 LOSS OF CELL SENSITIVITY TO ENDOGENOUS INTERFERON INDUCED BY MURINE SARCOMA VIRUS. (Fr.) Canivet, M. (Saint-Louis Hosp., Paris, France), J. Periés, M. Olivié and M. Boiron. *C R Acad Sci [D] (Paris)* 274(7):1106-1108, 1972.

Cultures of embryonic Swiss mouse cells infected with Maloney murine sarcoma virus (MSV), which are incapable of producing interferon, did produce interferon in the presence of Newcastle disease virus (NDV; Kansas strain) which had been irradiated with UV. When these cultures were inoculated with vesicular stomatitis virus 24 hr later, cells which had been inoculated with MSV + NDV were not protected while those inoculated with NDV alone were completely protected. Apparently MSV inhibits the protective action of endogenous cellular interferon, and the protection induced by irradiated NDV is a result of interferon production in the cells.

- 3092 STUDY OF THE TUMORIGENIC ACTIVITY OF SV40 VIRUS IRRADIATED WITH ULTRAVIOLET RADIATION IN THE SYRIAN HAMSTER. (Fr.) Wicker, R.

(Inst. Sci. Res. Cancer, Villejuif, France) and J. Coppey. *Int J Cancer* 9(3):626-631, 1972.

Syrian hamsters, at least 48 hr old, were inoculated s.c. with native SV40 virus (Hilleman's strain 777) or with SV40 virus which had been irradiated with UV radiation. Irradiation with 10,000 ergs/mm² enhanced the tumorigenic activity of the virus when at least 10⁵ viral particles were present in the inoculum. Enhanced tumorigenic activity resulting from irradiation was completely abolished by mixing control and irradiated virus. Tumors induced by a 1:10 dilution of irradiated virus appeared 4-5 weeks earlier than those induced with nonirradiated virus at the same dilution, while at a dilution of 1:1000 the tumorigenic activities of control virus and virus irradiated with 10,000 ergs/mm² of UV were the same. Tumor development and serum antibody titers for the T antigen of SV40 virus were the same in hamsters inoculated with control and irradiated virus. Irradiation of SV40 virus with 50,000 ergs/mm² UV greatly reduced its tumorigenic activity. It is suggested that tumors induced by SV40 virus irradiated with 10,000 ergs/mm² UV are partially defective in specific transplantation antigens and their growth is less dependent upon the immunological reaction of the host.

- 3093 COMPARATIVE STUDY OF RSV RESCUE FROM RSV-TRANSFORMED MAMMALIAN CELLS. (E.) Svoboda, J. (Inst. Exp. Biol. Genetics, Czechoslovak Acad. Sci., Prague), O. Machala, L. Donner and V. Sovova. *Int J Cancer* 8:391-400, 1971.

Five different lines of virogenic Rous sarcoma virus (RSV)-transformed mammalian cell lines (RSCH, RSH, RVA₂, B mix and XC) were fused with BLEF chicken embryo fibroblasts in the presence of Sendai virus. All individual heterokaryons produced infectious RSV. In contrast, nonvirogenic mammalian cells (RAV₄ and RVP₃), derived from tumors which arose in mice infected with RSV, did not give rise to infectious RSV, even when fused with chicken fibroblasts preinfected with three different types of avian leukosis "helper viruses" (RAV₄₉, RAV₅₀ or leukosis virus F-42). Fusion of four lines of virogenic cells (B mix, XC, RSCH and RVA₂) with mammalian fibroblasts of three different species as well as of virogenic Chinese hamster cells with chicken liver, mesonephros, thymus and macrophage cells did not lead to the formation of detectable RSV or RSV coat antigen. The presence of a "natural" Gs antigen in the indicator BLEF cells was not necessary for RSV rescue as fusion of cells derived from Gs negative chicken and duck embryos with virogenic cells also led to the formation of infectious RSV.

- 3094 MALIGNANT TRANSFORMATION OF HUMAN CELL *IN VITRO* BY THE SV40 DNA AND RELATED ALTERATION IN BIOLOGICAL ACTIVITY OF CELL MEMBRANES. (E.) Kimoto, T. (Okayama U. Med. Sch., Japan), E. Yokomura, Y. Shimizu, M. Yamakawa and S. Seno. *Acta Med Okayama* 25(2):77-86, 1971.

the addition of purified SV40 777 strain DNA (3 µg/ml) to the medium of cultured primary human or hamster embryonic cells, or to hamster kidney cells produced morphological transformation. T-antigen was detected after three months in transformed human cells, and both tumor specific and surface antigens were found in transformed hamster cells. Alterations in the membrane structures of normal and transformed human and hamster cells were determined by their capacity to phagocytize colloidal iron dextran sulfate (Cs-Fe) particles. Whereas transformed cells showed moderate phagocytic activity, their SV40 DNA-transformants were unable to incorporate the Cs-Fe particles. However, transformed cells treated with histone fractions (arg-rich, lys-rich or histone type II) at concentrations which did not affect growth or division showed a marked propensity to phagocytize the Cs-Fe particles when incubated with them for 25 hr. Electron microscopy revealed that ingested particles were incorporated into phagocytic vacuoles. These results indicated that definite changes occurred in the molecular structure of the membranes of cells transformed by purified SV40 DNA. From their phagocytic behavior in the presence of histone, it was concluded that the membrane changes were due to the disappearance of positively charged groups and/or the increase in negatively charged groups on the cell surface.

5 STRUCTURAL PROTEINS OF ADENOVIRUSES: VII. PURIFICATION AND PROPERTIES OF AN ARGININE-RICH CORE PROTEIN FROM ADENOVIRUS TYPE 2 AND TYPE 3. (E.) Prage, L. (Wallenberg Lab., Uppsala U., Sweden) and U. Pettersson. *Virology* 45(2):364-373, 1971.

Double viral core proteins from adenovirus types 2 (Ad2) and 3 (Ad3) labeled with ³H-arginine or ³H-methionine were extracted with acid and subjected to preparative polyacrylamide gel electrophoresis. Both Ad2 and Ad3 core proteins showed the same migration pattern irrespective of the isotope used. The molecular wt of the purified core protein was 17,000 as determined by sedimentation equilibrium centrifugation, and the sedimentation was 1.1S, suggesting an elongated molecular shape. The protein was apparently composed of one single polypeptide chain. Analysis of amino acid composition by an amino acid analyzer showed that the core protein was extremely high in arginine (21-23%) as well as in lysine (18-19%). The protein molecule was calculated to contain two tyrosine residues and one tryptophan residue per 17,000 daltons. The tryptophan residue probably occupied an unshielded position in the molecule. The N-terminal amino acid was determined by the dansyl chloride method to be alanine. No significant difference was observed in physicochemical properties between the arginine-rich core proteins purified from the two different serotypes. In immunodiffusion and complement fixation, the Ad2 and Ad3 core proteins were found to contain a common antigenic determinant. There were also antigenic differences between the core proteins of the different serotypes.

3096 GENETIC STABILITY OF THE SARCOMA VIRUSES IN MURINE AND AVIAN SARCOMA VIRUS-TRANSFORMED NONPRODUCER CELLS. (E.) Stephenson, J. R. (Natl. Cancer Inst., Bethesda, Md), E. M. Scolnick and S. A. Aaronson. *Int J Cancer* 9(3):577-583, 1972.

Clonal lines were obtained by a microtiter technique from cultures of normal rat kidney (NRK) and BALB/3T3 cells transformed by Kirsten murine sarcoma virus (Ki-MSV) or by Schmidt-Ruppin Rous sarcoma virus (SR-RSV). These clones, in which the virus did not productively replicate, were studied for the occurrence of spontaneous or chemical (BrdU or mitomycin-C)-induced morphologic reversion. Although no spontaneous revertants were detected, four morphologically revertant clones were obtained from over 10,000 transformed clones studied. One (K-NRK-R), which was isolated from a BrdU-treated Ki-MSV-transformed NRK culture, was further characterized. The K-NRK-R clone was similar to NRK control cells in saturation density and its ability to grow on monolayers. Infectious virus could be rescued from K-NRK-R cells by superinfection with murine leukemia virus, suggesting that the revertant line arose as a result of a mutation of a cellular gene involved in expression of the transformed state, and not from loss or mutation of the viral genome.

3097 FURTHER STUDIES ON THE MECHANISM OF GROWTH OF A TRANSPLANTABLE VIRUS-INDUCED LYMPHOID TUMOUR OF MICE. (E.) Croft, C. J. (Natl. Inst. Med. Res., London, England). *Int J Cancer* 9(1):212-218, 1972.

A lymphoid tumor, originally induced in CBA/H mice with Moloney virus, was passaged in CBA/H-T6T6 mice by s.c. transplantation or i.p. inoculation enabling mitotic host cells to be distinguished from donor cells by the presence of the T6 marker chromosomes. Three independent lines of evidence, based on chromosome analysis, indicated that mitotic host cells were stromal in nature, and were not host cells which had been altered into tumor cells under the action of the virus. Transplants of this tumor into neonatal or adult mice grew only by the proliferation of donor cells, and the cells of secondary tumors found in the spleens of mice bearing s.c. transplanted tumors were also derived from the cells inoculated. However, electron microscopy of tumor tissue sections consistently revealed the presence of C-type particles 100 nm in diameter, some of which were budding from the plasma membrane. In addition, intracytoplasmic and intracisternal A-type particles were commonly present. Thus, the possible role of Moloney virus in contributing to tumor growth by transformation of host cells in this system is still uncertain.

3098 PROPERTIES OF A MURINE SARCOMA VIRUS ISOLATED FROM A TUMOR ARISING IN AN NZW/NZB F1 HYBRID MOUSE: II. PHYSICAL AND BIOLOGICAL CHARACTERISTICS. (E.) Gazdar, A. F. (Natl. Cancer Inst., Bethesda, Md.), P. S. Sarma and R. H. Bassin. *Int J Cancer* 9(1):234-241, 1972.

The properties of a potent murine sarcoma virus (MSV), which was isolated after *in vivo* passage of a spontaneous tumor arising in an NZW/NZB F₁ hybrid mouse, are described. The agent had the morphological and growth characteristics of a C-type virus. Complement fixation tests using MuLV specific group-specific (gs) antibody showed that both the virus and sera from infected animals contained gs antigen. *In vivo* and *in vitro* neutralization studies and immulogic data indicated that the new MSV strain belonged to the FMR subgroup. The virus induced discrete, focal lesions in both 3T3 and secondary mouse embryo culture (MEC) cells. Focus formation usually followed a "two-hit" titration pattern (i.e., the number of foci decreased as the square of the virus dilution) when assayed on 3T3FL cells. MSV preparations also contained a large excess of an accompanying non-transforming C-type virus. The MSV was stable when stored at -70°C; it was ether-sensitive and had a buoyant density of 1.16 g/cm³ when centrifuged in sucrose density gradients. All these properties were similar to those of the Moloney (M-MSV), Harvey (H-MSV), and Kirsten (Ki-MSV) isolates of MSV. Partially purified virus concentrates of virus-induced mouse tumors rapidly induced tumors in newborn mice, rat, and hamsters. While the viruses produced by hamster and mouse tumors both contained the murine gs antigen, the host range of the MSV was altered by hamster passage. It failed to induce focal lesions in mouse and hamster cell cultures and did not induce sarcomas or leukemias when injected into newborn mice and hamsters. The antigenic properties and infectivity of the virus produced by hamster tumor cells were significantly different from the properties of the hamster leukemia pseudotype viruses obtained from hamster tumors induced by other strains of MSV.

3099 MORPHOLOGIC STUDIES OF A CYTOMEGALOVIRUS ISOLATED FROM AN OWL MONKEY. (E.)

Chopra, H. C. (Nat'l. Cancer Inst., Bethesda, Md.), B. J. Lloyd, Jr. D. V. Ablashi and G. R. Armstrong. *J Nat Cancer Inst* 48(5):1333-1340, 1972.

The ultrastructure of a herpes-type virus, characterized as a cytomegalovirus, isolated from the mouth cavity of an owl monkey and passaged in owl monkey kidney cells were studied. Nuclear and cytoplasmic inclusion bodies, characteristic of cytomegalovirus infection, were observed in infected cells. The pathogenesis of infected cells showed cytoplasmic swellings due to dilated and disorganized endoplasmic reticulum. Electron microscopy of these cells revealed herpes-type virus particles of several configurations. The nuclear virus particles, found in inclusions associated with chromatin aggregates, were either empty 80-90 nm diameter nucleocapsids or contained electron-dense nucleoids. Nucleocapsids with inner ring-type nucleoids were also common in the chromatin aggregates. Cytoplasmic particles were larger (160-190 nm diameter) and were single or clustered within vacuoles. Most cytoplasmic particles were enveloped in an outer envelope or coat. The nuclear particles appeared to

acquire the envelope from the nuclear membrane or from the vacuolar membranes within the cytoplasm. The enveloped particles represented the complete form of herpes-type virus particles. The process of virus release from infected cells could not be resolved.

3100 STUDIES ON A VIRAL NEPHROBLASTIC NEPHROBLASTOMA OF THE CHICKEN: AN ELECTRON MICROSCOPE COMPARISON OF THE SEQUENCE OF DEVELOPMENT OF THE VIRIONS IN DIFFERENT ORGANS. (E.) Weiler, O. (Gustave-Roussy Inst., Villejuif, France), E. Delain and F. Lacour. *Europ J Cancer* 7(6):491-494, 1971.

An ultrastructural study of a serially transmissible nephroblastoma line (DNV) showed the presence of virions morphologically similar to the avian leukosis group viruses. The particles were generally located in the basement membranes and the capillary endothelium. A chronological study of various tissues of brown Leghorn chicks which received i.p. injections of virus suspension indicated that the virus particles appeared and multiplied by 5-6 days exclusively in the main hematopoietic organs (spleen and bone marrow). After 10-12 days, the particles appeared in the viscera and were always found in considerable amount in the lung, liver, pancreas, ovary and digestive tract. In addition, virions were occasionally observed in heart muscle, the adrenal gland, and in the thigh bones (associated with osteoporosis). Virions appeared in the renal distal convoluted tubules after 25 days, and this was accompanied by a simultaneous decrease in virus production in the hematopoietic organs. Later, virions accumulated in the basement membrane, in the lumens of the tubules, and between the cells lining the distal convoluted tubules. Only the kidney underwent malignant transformation with occasional sarcoma production. Also, an unusual differentiation into cartilaginous or osteoid cell was sometimes observed, and these elements produced virus.

3101 INCREASE OF EPSTEIN-BARR-VIRUS-POSITIVE CELLS IN EB3 CULTURES AFTER TREATMENT WITH CIS-DICHLORO-DIAMMINE-PLATINUM (II). (E.) Vonka, V. (Inst. Sera Vaccines, Prague, Czechoslovakia), L. Kutinova, J. Drobnik and J. Brauerova. *J Nat Cancer Inst* 48(5):1277-1281, 1972.

Treatment of Burkitt Lymphoma EB3 cells, an Epstein-Barr Virus (EBV)-positive line, with the platinum compound, cis-dichloro-diammine-platinum (II) (1-10 µM, 20 hr), produced a two- to three-fold increase after three to seven days of cells showing a positive indirect immunofluorescence (IF) test with human sera possessing EBV antibody. Addition of cytosine arabinoside (10 µg/ml), or 5-bromo-2'-deoxyuridine (50 µg/ml) to the incubation medium prevented this enhancement, indicating that DNA synthesis was necessary for the effect. Incubation of treated cells under conditions of arginine deprivation or at high temperatures (32-39 °C) did not affect markedly the percentage of positive cells.

proximately the same increase in cells reactive in the IF test was observed in three EB3 sublines differing in their content of EBV-positive cells. Enhancement of the percentage of IF-positive cells was not observed in the EBV-positive P3J Burkitt lymphoma line. Both treated and untreated NC37 EBV-free peripheral leukocyte cultures were IF-negative.

02 ELUCIDATION OF THE NATURE OF THE MURINE ONCOGENIC VIRUS INHIBITOR ISOLATED FROM JLS-V5 CELL LINE. (E.) Turner, W. (Nat'l. Cancer Inst., Bethesda, Md.), P. Ebert, L. Riechers, J. W. Carson and M. A. Chirigos. *Proc Soc Exp Biol Med* 178(3):1030-1034, 1971.

Inhibitor (STAS) prepared by silicotungstic acid precipitation of the supernatant of JLS-V5 cells (mouse spleen-thymus cell line chronically infected with Rauscher leukemia virus) had previously been shown to inhibit Moloney murine sarcoma virus (MSV) focus-forming ability *in vitro*. The quantitative and temporal aspects of STAS-induced inhibition of MLV replication *in vitro* are reported in this communication. Growth of virus was inhibited in mouse embryo fibroblast (MEF) cells treated with STAS simultaneously with infection, or up to 48 hr after MLV infection, but not in cells pretreated with STAS before MLV infection. However, potent antiviral activity against MLV was also observed with similarly prepared inhibitor from the culture supernatant of the virus-free murine cell line, JLS-V9, from fetal calf serum (FCS), normal Balb/c mouse plasma, MEF+10% FCS, saline, or silicotungstic acid (TA). Inhibitor prepared from JLS-V5 supernatant and by precipitation with $ZnSO_4$, PCA, TCA, or ethanol instead of STA showed little or no activity against MLV *in vitro*. Preparations from JLS-V9 cells using ammonium sulfate as precipitant did show antiviral activity, suggesting the presence of an inhibitor not associated with residual STA in the STA preparation. No viricidal activity was observed when MLV was directly exposed to JLS-V5 STAS. These studies suggest that the active ingredient in the JLS-V5 is silicotungstic acid.

03 A NOVEL DNA POLYMERASE ACTIVITY FOUND IN ASSOCIATION WITH INTRACISTERNAL A-TYPE PARTICLES. (E.) Wilson, S. H. (Nat'l. Cancer Inst., Bethesda, Md.) and E. L. Kuff. *Proc Nat Acad Sci USA* 69(6):1531-1536, 1972.

DNA polymerase activity which promotes the synthesis of poly(dT) was found in association with intracisternal type particles isolated from five different mouse strains. A similar pattern of response was observed in the synthetic template-primer poly(rA)·(dT)₁₄ with reticulocyte polyribosomal RNA as template, suggesting that the A-type particle activity was capable of poly(dT) synthesis only by direction of poly(rA) sequences present in the natural RNA. The polymerase showed optimal activity in 100-250 mM KCl, 5 mM magnesium acetate ($MnCl_2$ was much less effective), and at pH 8.0-8.3, thus distinguishing it from RNA-dependent DNA polymerase activities associated with avian myeloblastosis virus and Rous sarcoma virus and from the poly(rA)-directed activity associated with Rauscher murine leukemia virus (MuLV). No significant incorporation of dAMP, dGMP or dCMP was detected in the presence of several RNA and DNA template-primers. Enzyme activity was not detected in preparations from several normal and MuLV-infected cell types which did not contain A-type particles. Except for a low level of activity in response to poly(rC)·(dG)₁₄, both the patterns of response to template-primers and the divalent cation preference of the A-type particle activity differed from that of the MuLV (C-type particle) activity. Antiserum against MuLV DNA polymerase failed to inhibit the poly(rA)·(dT)₁₄-dependent activity of A-type particles under conditions nearly optimal for MuLV activity.

3104 CHARACTERIZATION OF MURINE RAUSCHER LEUKEMIA VIRUS PROPAGATED IN HUMAN CELLS. (E.) Ablashi, D. V. (Nat'l. Cancer Inst., Bethesda, Md.), W. Turner, G. R. Armstrong and L. R. Bass. *J Nat Cancer Inst* 48(3):615-621, 1972.

Human embryonic kidney (HEK) cells were infected with Rauscher leukemia virus (RLV), and after infection was confirmed by a positive complement fixation (CF) test, indicating induction of mouse group-specific antigen synthesis, the RLV was further passed in HEK cells and designated human Rauscher virus (HRV). Mouse embryonic fibroblast (MEF) cells infected with HRV which had been serially passaged in HEK cells for up to nine passages gave a positive XC response. After ten passages in HEK cells, however, HRV was unable to infect MEF cells. HRV was effectively neutralized by both goat and rabbit anti-HRV sera, whereas murine RLV was neutralized by goat anti-HRV, but not by rabbit anti-HRV. Although inoculation of passage five HRV into weanling BALB/c mice induced splenomegaly, inoculation of two higher passages (12 and 20) did not, indicating a rapid loss of leukemogenicity of HRV. Inoculation of the supernatant from infected MEF cell cultures likewise failed to induce splenomegaly or virus-specific CF antigen in the spleen.

3105 REOVIRUS-SPECIFIC RIBONUCLEIC ACID FROM POLYSOMES OF INFECTED L CELLS. (E.) Ward, R. (Roche Inst. Molecular Biol., Nutley, New Jersey), A. K. Banerjee, A. LaFiandra and A. J. Shatkin. *J Virol* 9(1):61-69, 1972.

Polysomes from actinomycin D-treated mouse L cells infected with reovirus type 3 were purified on glycerol gradients and analyzed for RNA and protein content. Transcription of the reovirus genome resulted in the production of ten distinct species of single-stranded RNA (ssRNA), which were separated in glycerol gradients into three size classes: three large (l), three medium (m), and four small (s). Analysis of ³H-adenosine-labeled ribonuclease-treated reovirus RNA indicated that little,

if any, of the reovirus A-rich RNA was present in polysomes. Although all ten reovirus genome segments were transcribed, only six or seven new proteins were identified in infected cells by polyacrylamide gel electrophoresis. Chromatography of pancreatic RNase hydrolysates of ^{32}P -labeled polysome-associated reovirus mRNA indicated that the 5'-terminus of polysome ssRNA was ppGpYp (Y = pyrimidine) and was identical to the 5'-termini of reovirus genome segments and to ssRNA synthesized *in vitro* by the virion-associated RNA polymerase, as previously reported. RNA isolated from both heavy (>30 ribosomes) and light (five to eight ribosomes) polysomes included similar amounts of 1, m and s ssRNA, suggesting that linkage of the genome segments observed in virions may occur at the single-strand stage of reovirus RNA replication.

3106 ABSENCE OF RIBONUCLEIC ACID METHYLASE IN THE AVIAN MYELOBLASTOSIS VIRUS CORE.

(E.) Gantt, R. (Natl. Cancer Inst., Bethesda, Md.), K. Stromberg and B. Julian. *J Virol* 9(6):1057-1058, 1972.

N^2 -guanine-RNA-methylase had previously been shown to be associated with avian myeloblastosis virus (AMV). To determine whether or not the enzyme was a core component of the virion, intact and surfactant-disrupted AMV preparations were subjected to isopycnic sucrose density gradient centrifugation, and different areas of the gradients were assayed for methylase activity. Although methylase activity was associated with intact virions, disruption with the surfactant, Sterox SL, released 75% of the activity into a lipoprotein fraction which banded at the top of the gradient. Since electron microscopic observation showed that core material from untreated and treated virus preparations was identical, it was unlikely that the methylase was loosely bound to the virus core and that it was released during the process of core isolation. It was therefore concluded that the specific methylase activity was not a core constituent under these conditions.

3107 MORPHOLOGICAL TRANSFORMATION *IN VITRO* OF HUMAN FIBROBLASTS BY EPSTEIN-BARR VIRUS: PRELIMINARY OBSERVATIONS. (E.) Probert, M. (U. Bristol Med. Sch., England) and M. A. Epstein. *Science* 175(4018):202-203, 1972.

Human embryonic skin and muscle fibroblasts were incubated in suspension culture with partially purified Epstein-Barr (EB) virus, and some of the cells were exposed to inactivated Sendai virus. All cells were then grown in monolayer cultures. Although both groups exhibited signs of morphological transformation (colonies of piled-up polygonal cells), Sendai virus-exposed cultures contained seven times as many transformed colonies as did cultures exposed only to EB virus. The polygonal colonies had fine structural features of altered fibroblasts and did not release EB virus.

3108 *IN SITU* HYBRIDIZATION OF ADENOVIRUS RNA AND DNA. (E.) McLaughlin, J. E. (U.

Birmingham Med. Sch., England), A. R. Dunn and K. M. Jones. *Nature* 236(5346):346-348, 1972.

The relationship between the adenovirus type 12 (Ad12) genome and host human embryonic lung (HEL) cell chromosomes was investigated by a hybridization-autoradiography technique. Isotopically labeled complementary viral RNA (cRNA) was synthesized from a purified viral DNA template. Slides of fixed, uninfected and infected, HEL cells were treated with acid to denature the DNA and then incubated with Ad12 cRNA. Autoradiographs of these preparations showed that the grain distribution and count over non-dividing nuclei of infected cells varied with time after infection. The numbers of labeled nuclei were clearly related to multiplicity of infection. In the metaphases from virus-infected cultures, the number of grains was unusually low, indicating that in cells reaching mitosis during the 48-hr period postinfection, there had usually been little or no synthesis of viral DNA. Specific damage induced by Ad12 to chromosome No. 17 was present in up to 40% of the metaphases, but grains were only rarely found in association with this locus. Distribution of grains over the entire karyotype was random. These findings showed that the sites of chromosomal damage were not necessarily those associated with the sites of major viral DNA accumulation. They also tended to confirm previous results which indicated that viral DNA synthesis was not required for the induction of chromosome aberrations by adenovirus. In addition, these results indicated that few cells were capable of undergoing mitosis after massive viral DNA synthesis had occurred.

3109 PROPERTIES OF POLYOMA VIRUS-TRANSFORMED CELLS: II. CHARACTERISTICS OF THE VIRUS-SPECIFIC RNA. (E.) Hudson, J. B. (Dept. Microbiol., U. British Columbia, Vancouver, Canada). *Canad J Microbiol* 18(2):247-254, 1972.

The polyoma virus-specific RNA (Py RNA) synthesized in a line of polyoma-transformed hamster cells was characterized and compared with the viral-specific RNA synthesized "late" in productively infected mouse cells. The PyRNA from the transformed cells sedimented heterogeneously on sucrose gradients with large amounts of PyRNA in the >40S region. The overall sedimentation profile resembled that of "late" PyRNA synthesized in mouse cells. Competition hybridization experiments demonstrated that the bulk of the PyRNA sequences, in the transformed cells, were different from the "late" PyRNA sequences. An estimate of the average number of viral genomes per transformed cell was made by using DNA-DNA hybridization experiments (with polyoma DNA of high specific reactivity). The PyH-1 cells did not contain more than two, and possibly less than one, viral genome per cell. The data suggest that the PyH-1 cells may contain only a fraction of a Py genome, possibly only comprising "early" genes

ence the inability to rescue infectious virus), and that the viral RNA transcribed is covalently linked to host cell RNA moieties.

10 PURIFICATION AND CHARACTERIZATION OF THE DEOXYRIBONUCLEIC ACID POLYMERASE ASSOCIATED WITH ROUS SARCOMA VIRUS. (E.) Faras, A. J. Dept. Microbiol., U. California, San Francisco), M. Taylor, J. P. McDonnell, W. E. Levinson and M. Bishop. *Biochemistry* 11(12):2334-2343, 1972.

The DNA polymerase associated with the Schmidt-Ruppin strain of Rous sarcoma virus was purified a minimum of 500-fold by successive chromatography in the presence of nonionic detergent on DEAE-cellulose, phosphocellulose and Sephadex G-100, followed by glycerol gradient centrifugation. Two fractions (A and B) of activity were eluted from phosphocellulose. Form B comprised 90% of total enzyme activity and had a molecular weight of 105,000. Form A constituted 10% of the total activity, had a molecular weight of 96,000, and was in equilibrium with form B. The proportional template responses for DNA and 70S RNA were identical for the two forms. The purified enzyme was completely template-dependent and free of appreciable amounts of RNase. A similar enzyme response to various templates (endogenous viral RNA, synthetic polynucleotides and exogenous DNA) at all stages of enzyme purification indicated that all template activities resided on the same protein or protein complex. Optimal concentrations for enzyme activity of H⁺, Mg⁺⁺ and Mn⁺⁺ were similar or identical for all three templates. Monovalent cations (Na⁺, K⁺ and NH₄⁺) inhibited enzyme response to both RNA and DNA templates. A K_m for TTP of 2×10^{-5} M was calculated from double reciprocal plots for the initial linear phase of DNA synthesis with viral RNA as template. The amounts of DNA synthesized using the three different templates supported the view that the enzyme carried out only repair synthesis. Comparison of the responses to a number of RNA and DNA-virus-, human RNA- and synthetic templates showed that the 70S oncornavirus RNA was the most efficient template. Purified enzyme preparations had no DNase (pH 5.0 and 8.1) or phosphatase (pH 8.1) activity.

11 ULTRAVIOLET INACTIVATION OF MOLONEY LEUKAEMIA VIRUS: RELATIVE TARGET SIZE REQUIRED FOR VIRUS REPLICATION AND RESCUE OF "DEFECTIVE" MURINE SARCOMA VIRUS. (E.) Nomura, S. Natl. Cancer Inst., Bethesda, Md.), R. H. Bassin, Turner, D. K. Haapala and P. J. Fischinger. *J Virol* 14:213-217, 1972.

Moloney murine leukemia virus (MuLV) suspensions of 10⁶ and 10⁷ IC stocks were irradiated with UV light. Samples were removed at various times during irradiation and assayed for infectivity by either focus induction assay in S+L- cells or XC plaque assay after infection of normal 3T3 cells. Virus

inactivation followed single-hit kinetics. Non-specific effects of ionization on virus infectivity were not observed. A microplate technique for focus induction in S+L- cells was used to determine the ability of the UV-irradiated, non-replicative MuLV stocks to rescue murine sarcoma virus (MSV), but no such ability could be demonstrated. The fact that the ability of MuLV to rescue MSV from S+L- cells and its ability to replicate were equally sensitive to UV irradiation indicated that the entire genome of MuLV was necessary for the rescue of "defective" MSV. The results were also consistent with the assumption that MuLV provides the outer coat for MSV as one of the final steps in the formation of infectious virus. Data indicated that MuLV replication was essential for focus formation in S+L- cells by MuLV. There was no evidence that the MSV genome present in S+L- cells could complement or in some other way reactivate a partially inactivated MuLV genome.

3112 ENHANCING EFFECT OF EXCESS TOPICAL VITAMIN A ON ROUS SARCOMAS IN CHICKENS. (E.) Polliack, A. (Hebrew U. Med. Sch., Jerusalem, Israel) and Z. B. Sasson. *J Nat'l Cancer Inst* 48(2):407-416, 1972.

The right and left wing webs of 36 White Leghorn chickens of both sexes were inoculated with the Schmidt-Ruppin strain of Rous sarcoma virus (SR-RSV), in various amounts, ranging from 5,000 to 100,000 focus-forming units (FFU) per injection. Thereafter, the right wing webs were painted daily with topical 20% vitamin A palmitate in paraffin oil for three weeks. The left wing webs remained untreated for a similar period. In the untreated left wing web 22.2% of the birds developed fibrosarcomas of 1- to 2-cm diameter and 6- to 30-g weight. In the vitamin A-treated right wing webs, 52.8% had large tumors weighing up to 240 g and measuring from 6-13 cm in diameter. Tumors developed in 50% of the webs given smaller doses of SR-RSV (5,000-20,000 FFU) followed by topical vitamin A, as opposed to 15% in webs given similar doses of SR-RSV alone. The tumors developing after topical vitamin A were shown to be more aggressive both macroscopically and histologically; they infiltrated muscle and bone and also metastasized, and large amounts of mucopolysaccharides were detected in the stroma by special stains. When the wings of ten chickens were treated with topical vitamin A palmitate before infection with SR-RSV, tumors weighing from 6-20 g developed in all treated webs, whereas tumors weighing only from 1-5 g developed in six of ten untreated wing webs. The results were attributed to the established membrane-labilizing qualities of vitamin A which probably enhanced tumorigenesis, either by facilitating more effective entry of the virus into the tissues or by altering the structure and function of the virus and target cell in a manner more amenable to malignant transformation.

3113 INOCULATION OF CALVES WITH PARTICLES RESEMBLING C-TYPE VIRUS FROM CULTURES OF

BOVINE LYMPHOSARCOMA. (E.) Miller, L. D. (Dept. Vet. Sci., U. Wisconsin, Madison), J. M. Miller and C. Olson. *J Nat Cancer Inst* 48(2):423-428, 1972.

Lymphocyte cultures containing C-type-like virus particles were obtained from two cows with lymphosarcoma and one with lymphocytosis. Following stimulation with phytohemagglutinin or Concanavalin A, cells were introduced orally or by i.p. or i.v. injection into 16 calves; the existence of C-type-like particles in these inocula had been confirmed by electron microscopy. The number of circulating lymphocytes was determined in each calf at two-month intervals after inoculation. Short-term cultures of circulating lymphocytes from inoculated calves were prepared at intervals of two months or less. C-type-like particles morphologically identical to those described in cattle with lymphosarcoma were observed by electron microscopy in lymphocyte cultures from all calves (including one inoculated with cell-free material) 2-13 months post-inoculation. Virus-positive cultures appeared earliest in calves which were inoculated either on the first day of life or with larger volumes of material. Calves inoculated orally showed the longest delay before appearance of cultures with C-type-like particles. Five calves developed persistent lymphocytosis which first appeared 4-13 months post-inoculation. In each case, demonstration of C-type-like particles preceded development of lymphocytosis.

3114 ORAL INFECTION OF NEWBORN GUINEA PIGS WITH HERPES SIMPLEX VIRUS TYPE 1. (E.) Blaskovic, D. (Komensky U., Czechoslovakia), J. Svobodova, K. Weidnerova and B. Stastny. *Acta Virol* 15:522, 1971.

Newborn guinea pigs were inoculated orally with type 1 herpes simplex virus (HSV) strain KL70 ($2.5 \times 10^{6.5}$ TCID₅₀/ml or a 10^{-1} dilution of this). Two of the eight animals infected with 10^{-1} dilution of HSV developed tongue ulcers 48 hr post-infection (p.i.). No virus could be isolated from these lesions. HSV was recovered from only one animal which died nine days p.i. (10^{-1} dilution) and was detected in suspensions of tongue, esophagus, trachea and lung. HSV was identified by a virus neutralization test, immunofluorescence and bright fluorescence. Sera taken from surviving infected animals 4-6 days p.i. contained no antibodies against HSV type 1, as determined by the virus neutralization test. Attempts to isolate HSV from organs of animals sacrificed 2.5 months p.i. were also unsuccessful.

3115 VIRUS-SPECIFIC RIBONUCLEIC ACID IN CELLS PRODUCING ROUS SARCOMA VIRUS: DETECTION AND CHARACTERIZATION. (E.) Leong, J.-A. (Dept. Microbiol., U. California, San Francisco), A.-C. Garapin, N. Jackson, L. Fanshier, W. Levinson and J. M. Bishop. *J Virol* 9(6):891-902, 1972.

Viral RNA from cells producing the Schmidt-Ruppin strain

of Rous sarcoma virus (RSV) was localized and characterized. Purified 70S RSV RNA was used to direct synthesis of ³H-labeled complementary DNA. Hybridization of the virus-specific radio-labeled DNA to whole cell RNA or to RNA from cell fractions was detected by two procedures: fractionation on hydroxyapatite columns or the extent of hydrolysis with single strand-specific *Neurospora* and *Aspergillus* nucleases. Similar results were obtained with both procedures. The RNA-DNA hybrids were completely resistant to single strand-specific nuclease and showed almost the same melting-curve configuration as hybrids synthesized enzymatically, suggesting a very high degree of precision in base-pairing. Results from hybridization of virus-specific DNA to whole cell RNA agreed with previous reports and indicated that approximately 0.5% of infected cell RNA were virus-specific sequences. Virus-specific RNA was present in both the nucleus and cytoplasm of infected cells. Results from hybridization with virus-specific DNA after rate-zonal centrifugation of RNA extracted from cells at 25 C (which preserves the secondary structure of 70S RNA), showed that virus-specific RNA was remarkably heterogeneous in size. Some RNA molecules, which were probably restricted to the nucleus, sedimented in their native state (90-95S) more rapidly than the viral genome. The nature of the RNA found in cytoplasmic fractions varied from preparation to preparation, but heterogeneous RNA (4-50S), smaller than the viral genome, was always present in significant amounts along with the 70S RNA.

3116 ULTRASTRUCTURAL COMPARISON OF A VIRUS FROM A RHESUS-MONKEY MAMMARY CARCINOMA WITH FOUR ONCOGENIC RNA VIRUSES. (E.) Kramarsky, B. (Inst. Med. Res., Camden, N.J.), N. H. Sarkar and D. H. Moore. *Proc Nat Acad Sci USA* 68(7):1603-1607, 1971.

The ultrastructure and morphogenesis of Mason-Pfizer monkey virus (M-PMV), isolated from a mammary carcinoma in a Rhesus monkey, was compared with those of murine mammary tumor virus (MuMTV), murine leukemia virus (MuLV), L1210 leukemia-associated virus, and avian myeloblastosis virus. The simian virus resembled MuMTV and the L1210 virus in that it produced intracytoplasmic particles that were enveloped during budding. It resembled L1210 virus and MuLV in budding with smooth envelopes. It differed from all the others in being more fragile. This fragility is probably due to an inherent tendency of the supercoiled nucleocapsid to unwind, exerting a pressure upon the virion envelope. The similarities suggest that the monkey virus is an oncogenic virus.

3117 MITOCHONDRIAL DNA FROM CELLS TRANSFORMED BY ADENOVIRUSES AND SV40. (E.) Riou, G. (Inst. Gustave-Roussy, Villejuif, France) and E. Delain. *Biochimie* 53(6-7):831-836, 1971.

Mitochondrial DNA (mtDNA) isolated from mitochondria of tumors produced in newborn hamsters by injections

adenovirus 7 or adenovirus 12, then cultured and maintained in tissue culture and mtDNA isolated from mitochondria of SV40-transformed hamster embryo (HSE) cells were studied. Equilibrium centrifugation of mtDNA in CsCl ethidium bromide gradients resulted in the resolution of two bands of DNA. Electron microscopic analysis of the DNA of the heavier band showed several molecular forms. The mtDNA from these cells has the same buoyant density and the DNA of the heavier bands from the transformed cells showed a narrow band with the same buoyant density ($\rho=1.699$ g/ml), as that from untransformed hamster embryo cells. The mtDNA from cells transformed by the adenoviruses had a large proportion of normal circular oligomers which were not seen in the control hamster embryo fibroblasts. A low proportion of circular dimers, but an unusually high proportion of catenated oligomers, were seen in cells transformed by SV40 or cells spontaneously transformed following successive subculture.

18 EPSTEIN-BARR VIRUS: TRANSFORMATION, CYTOPATHIC CHANGES, AND VIRAL ANTIGENS IN SQUIRREL MONKEY AND MARMOSET LEUKOCYTES. (E.) Miller, G. (Yale U. Sch. Med., New Haven, Conn.), Shope, H. Lisco, D. Stitt and M. Lipman. *Proc Acad Sci USA* 69(2):383-387, 1972.

Human lymphoblastoid cell lines (SLCL) were established in leukocyte cultures that were exposed to Epstein-Barr virus (EBV) from four adult squirrel monkeys and from one cotton-top marmoset. Only one of 26 squirrel monkey cultures (from six monkeys) and one of six marmoset cultures (from two monkeys) were transformed, in comparison to transformation of all seven human cultures that were exposed to EBV (from one subject). Transformation appeared earlier in the monkey cells than in the human cells. The following evidence supports the hypothesis that EBV was responsible for transformation of the monkey cells. First, EBV antigens were detected by immunofluorescent and complement fixation methods in the transformed cells, EBV particles were seen in the cell line by electron microscopy, and infectious virus was present in both cell lines. Second, the monkey cells that were the source of the transformed leukocytes did not possess EBV antibodies detectable by complement fixation test, and thus were presumably noncarriers of EBV. Third, SLCL formed only in cultures exposed to EBV and not in unexposed cultures. Fourth, the cytopathology seen regularly in the B95-8 line of transformed leukocytes and occasionally in the B95-15 line of squirrel monkey leukocytes, consisting of multinucleated cells with intranuclear inclusions, was compatible with cytopathic effects described for the herpesvirus group, of which EBV is a member. Fifth, the SLCL did not yield cytopathic agents when cocultivated as intact cells or cell extracts in monolayer cultures known to be sensitive to human herpesviruses such as Herpes Salmir. Finally, there was no evidence in the SLCL for the presence of other antigens that reacted with the sera of animals whose leukocytes were transformed.

3119 ERYTHROPOIETIC RESPONSES OF MICE TO INFECTION WITH RAUSCHER LEUKEMIA VIRUS. (E.)

Ebert, P. S. (Natl. Cancer Inst., Bethesda, Md.), N. E. Maestri and M. A. Chirigos. *Cancer Res* 32(1):41-47, 1972.

Erythroblastosis, reticulocytosis, splenomegaly and anemia characterize the prelymphoid leukemic phase of Rauscher leukemia virus (RLV) infection. After RLV (0.2 ml of undiluted spleen extract) was inoculated into 4 to 6 wk-old male Balb/c mice, reticulocyte counts increased and RBC, hematocrit, and hemoglobin levels decreased progressively until the 29th day, followed by a slight increase in all three parameters by the 35th day. Splenic and hepatic δ -aminolevulinic acid synthetase activity, per gram of tissue, decreased, as compared with normal activity, but the spleen increased to 25 times its normal size, and therefore, the net δ -aminolevulinic acid synthetase activity increased 1340% compared to normal spleen activity. Liver weight increased slightly throughout the 35-day observation period, but liver enzyme activity per gram of tissue decreased steadily to 30% of the normal level on the 35th day. Phenylhydrazine treatment was given, to mimic RLV infection, and the mice showed a threefold increase in the specific activity of splenic δ -aminolevulinic acid synthetase but only a small increase in spleen size. The results suggest that the RLV-induced anemia does trigger the same erythropoietic response as does drug-induced anemia. When erythropoietin (ESF) production in RLV-infected mice was studied, low levels of ESF were found in plasma from mice infected with RLV for seven to 35 days, but the ESF activity was inappropriate for the extent of the anemia. Bleeding of RLV-infected mice to stimulate ESF production produced no response, suggesting possible erythropoietic blocking factors, although none were demonstrated.

3120 COMPARISON OF THE EFFECTS OF INOCULATION ROUTES AND VIRAL PREPARATIONS ON LEUKEMOGENESIS. (E.) Mariani, T. (U. Minnesota, Minneapolis), P. B. Dent and R. A. Good. *Proc Soc Exp Biol Med* 138(3):889-892, 1971.

The relative effectiveness in leukemogenesis of the intrathymic and i.p. route of inoculation with Gross passage A (GPA) virus from leukemic tissues or from peritoneal fluid is compared. When inbred 2- to 5-day-old C3H/BI mice were given injections of cell-free filtrates of leukemic tissues, intrathymic administration was more efficient in inducing leukemia than i.p. inoculation. Although the intrathymic dose was only one half of the i.p. dose, 100% of the animals receiving intrathymic injection developed leukemia whereas 82% of those inoculated i.p. developed leukemia. In a second series of experiments cell-free ascitic fluid from animals with transplantable Gross lymphoma was used; all animals receiving the virus intrathymically contracted leukemia, as did 96% of the mice given i.p. injections. It was also found that intrathymic virus injection decreased the latent

period in leukemogenesis. These results support the conclusion that the thymus is a site for primary virus-cell interaction during leukemogenesis.

3121 COMBINED NEOPLASTIC EFFECTS OF VACCINIA VIRUS AND 3-METHYLCHOLANTHRENE. II.

GENETIC FACTORS. (E.) Lilly, F. (Albert Einstein Coll. Med., Bronx, N.Y.) and M. L. Duran-Reynals. *J Nat Cancer Inst* 48(1):105-112, 1972.

Female BALB/c and AKR mice, female offspring of crosses of these two strains, and female offspring of the backcrosses (BALB/c x AKR) F_1 x BALB/c and (BALB/c x AKR) F_1 x AKR, were treated with combinations of cortisone (1 mg daily for five days s.c.), vaccinia virus i.d., and 3-methylcholanthrene (MCA) (1% solution painted daily for five days on shaved flank), and susceptibility to vaccinia dermal infection after cortisone, and to papillomas induced by MCA, was observed. BALB/c parents were highly susceptible to vaccinia dermal infection following cortisone, and to MCA tumorigenesis. AKR parents were resistant to both treatments. F_1 offspring of (BALB/c x AKR) and (AKR x BALB/c) crosses were uniformly susceptible to vaccinia dermal infection, although these offspring were not as highly susceptible as the BALB/c parents. MCA tumorigenesis was enhanced in F_1 hybrids by active vaccinia dermal infection; 15 of 31 F_1 mice given cortisone and MCA, but no vaccinia, developed papillomas, whereas 37 of 43 mice given cortisone and MCA plus vaccinia developed papillomas. Although AKR parents were resistant to vaccinia, 78% of the offspring of the backcross (BALB/c x AKR) F_1 x AKR showed an acute, ulcerative response to the virus. Statistical analysis indicated that susceptibility to vaccinia infection was due to two genes. Backcross studies also showed that enhancement of MCA tumorigenesis by vaccinia depended on mice being genetically susceptible to active infection with vaccinia. The incidence of spontaneous leukemia among mice of the (BALB/c x AKR) F_1 x AKR generation was 41%. Leukemia was more frequent among backcross mice resistant to vaccinia infection than among those susceptible to vaccinia. (55 vs 36%, resp.) It is thought that *H-2* or a closely linked gene is a factor in determining degree of susceptibility to MCA skin tumorigenesis in backcross offspring.

3122 HELPER ACTIVITY OF HUMAN LEUKEMIC TISSUE EXTRACTS FOR LEUKEMIA VIRUS EXPRESSION IN MICE. (E.) Steeves, R. A. (Roswell Park Mem. Inst., Buffalo, N.Y.), A. Fjelde and E. A. Mirand. *Proc Nat Acad Sci USA* 68(10):2391-2395, 1971.

BALB/c mice and their hybrids with DBA/2 mice both carry the *Fv-1^D* allele, which reduces the efficiency of spleen focus formation by N-tropic strains of Friend leukemia virus. The spleens of these resistant mice were subjected *in vivo* to both spleen focus-forming virus (SFFV) and tissue culture extracts of spleens from patients with hematopoietic neoplasms to discover whether a helper virus of the

C-type is employed in human leukemia. Helper activity was definitely found in the human leukemia forms, particularly in chronic myelogenous leukemia, and showed many similarities to that observed with murine leukemia virus (MuLV) preparations. It was readily sedimented from tissue culture supernatant fluids, it required injection along with an N-tropic SFFV indicator into a resistant B-type host, and it was sensitive to UV light. However, preliminary electron microscopy has not revealed obvious C-type or other virus-like particles in the human extracts. Also, it has been impossible to demonstrate rapid growth of the helper-inducing entity in mice or to convert antigenicity of SFFV by mixed "infection" of suckling B-type mice. Finally, MuLV-infected spleen cells seem to be more active *in vitro* than human spleen cells.

3123 HERPES ZOSTER: DEMONSTRATION OF VIRUS IN TRIGEMINAL NERVE AND GANGLION BY IMMUNO-FLUORESCENCE AND ELECTRON MICROSCOPY. (E.) Esiri, M. M. (Public Hlth. Lab., Radcliffe Infirmary, Oxford, England) and A. H. Tomlinson. *J Neurol Sci* 15(1):35-48, 1972.

A successful demonstration of varicella-zoster virus in nerve and ganglion is reported. Autopsy material from a patient who died four days after the onset of ophthalmic herpes zoster included skin, the first division of the trigeminal nerve and the trigeminal ganglion. These specimens were examined by conventional histological methods, electron microscopy, immunofluorescence and virus culture. Skin showed virus particles in the nuclei and cytoplasm of epidermal cells. Neural tissue was found to have virus particles present in the cytoplasm of the perineurial cells, in the cytoplasm and nuclei of Schwann cells and exhibited degeneration of axons and myelin of the frontal nerve. A detailed study of the trigeminal nerve showed severe ganglion cell degeneration and satellite cell disarray at specific sites. Virus was not isolated in tissue culture. These findings suggest that varicella-zoster virus spreads in peripheral nerves by growth in endoneurial cells. The value of using immunofluorescence and electron microscopy for virus infection studies of the nervous system is stressed.

3124 INTEGRATION OF SIMIAN VIRUS 40 DEOXYRIBONUCLEIC ACID INTO THE DEOXYRIBONUCLEIC ACID OF PERMISSIVE MONKEY KIDNEY CELLS. (E.) Hirai, K. (Wistar Inst. Anatomy Biol., Philadelphia, Pa.) and V. Defendi. *J Virol* 9(4):705-707, 1972.

The integration of SV40 DNA into the genome of permissive African green monkey kidney (CV-1) cells was studied by DNA-RNA hybridization. Infected confluent CV-1 cultures were split and grown in D-arabinosyl cytosine (Ara-C, 15 μ g/ml). At various times thereafter, DNA was purified from isolated nuclei by the pH phenol method and C_3Cl_4 equilibrium density centrifugation. Association of SV40 DNA to

SV40 DNA began at about 20 hr postinfection and remained at a constant level up to about 48 hr. The total amount of free SV40 in nuclei progressively increased. Alkaline sucrose gradient centrifugation of a mixture of ^{14}C -leucine- and ^{14}C -lysine-labeled CV-1 nuclei and ^3H -labeled SV40 DNA showed that nuclear DNA was clearly separated from SV40 DNA and protein. At six hr postinfection, most of the DNA hybridizable with ^3H -labeled SV40 complementary RNA (c-RNA) was present in the fractions representing free SV40 DNA. However, at 30 hr postinfection, most of the hybridizable DNA was associated with high-molecular-weight cellular DNA by stable linkages. When CV-1 cells were infected in the absence of Ara-C, a large fraction of the DNA hybridizable with SV40 cRNA was found in the fraction corresponding to SV40 DNA component 1 (3S). The specific activity of hybridizable DNA in the faster-sedimenting fractions was similar to that of the corresponding fractions of cells infected in the presence of Ara-C. It was thus concluded that SV40 DNA was integrated into the DNA of CV-1 cells during the early phases of the replicative cycle of the virus.

5 LOCATION OF FELINE LEUKEMIA-SARCOMA GROUP-SPECIFIC ANTIGEN IN INFECTED HUMAN TISSUE CULTURE CELLS. (E.) Ubertini, T. R. (Cornell U., Ithaca, New York). *Infect Immun* 5(3):400-405, 1972.

Human embryo cells were infected *in vitro* with feline leukemia virus (FeLV, Rickard strain) and feline sarcoma virus (FeSV, GA isolate) and were cultured for seven passages. Infected and uninfected control cell cultures were then prepared for immunofluorescent and immunoenzymatic studies at both the light and electron microscope levels. Both techniques showed the presence of feline leukemia-sarcoma group-specific antigens in the infected cells. The antigens were found to be exclusively cytoplasmic, diffuse and located in discrete cytoplasmic foci. Electron microscopic observation indicated that the antigens were located around lysosomal aggregates. It appeared, therefore, that antigenic expression of the viral genome of FeLV and FeSV followed a pattern similar to that of a variety of oncogenic RNA viruses of various families.

6 COMPARISON OF MURINE SARCOMA VIRUSES IN NONPRODUCER AND S^+L^- -TRANSFORMED CELLS. Aaronson, S. A. (Nat'l. Cancer Inst., Bethesda, Md.), R. H. Bassin and C. Weaver. *J Virol* 9(4):701-707, 1972.

The genetic properties of murine sarcoma virus (MSV) transformed nonproducer rat NRK and transformed sarcoma-positive, leukemia-negative (S^+L^-) mouse 3T3 cells were studied. Whereas the nonproducer cells showed no evidence of spontaneous virus production or viral antigens, the S^+L^- cells released biologically inactive virus-like particles and contained

murine leukemia virus (MuLV) antigens. Each virus was found to be genetically stable through at least two cycles of rescue (by infection with MuLV or treatment with bromodeoxyuridine) and transmission to new cells, as determined by analysis of infectious MSV and MuLV production, MuLV complement-fixation antigens, and virus particle production. The fact that the MSV genomes rescued from nonproducer and S^+L^- cells reproduced their respective phenotypes in a common assay cell (NRK) indicated that cellular factors were not responsible for the observed differences in the behavior of the two viral genomes. The observation that none of the focus-derived lines produced by MSV rescued from S^+L^- cells was of the nonproducer type was consistent with the hypothesis that the MSV genomes present in the nonproducer and S^+L^- cells differed, the latter containing genetic information for at least some viral replication functions. There was no evidence for production of a defective MuLV by S^+L^- cells.

3127 SEPARATION OF RETICULOENDOTHELIOSIS VIRUS FROM AVIAN TUMOR VIRUSES. (E.)

Maldonado, R. L. (Dept. Microbiol., U. Texas, Austin) and H. R. Bose. *J Virol* 8(5):813-815, 1971.

Velocity sedimentation in sucrose was used to separate the reticuloendotheliosis virus (REV) from viruses of the avian tumor group. Rous sarcoma viruses with the envelopes from avian leukosis viruses RAV-2 and RAV-3 were used as representatives of the avian tumor virus. The viruses were cultured separately in secondary chicken embryo cell cultures with Eagle's medium. The monolayers were treated with diethylaminoethyl dextran to enhance virus attachment. Two days after infection ^3H -uridine was added to the REV-infected cultures, and $^{32}\text{PO}_4^{3-}$ was added to the RSV-infected cultures. After a 48-hr labeling period, the culture fluids were removed and the virus particles were concentrated by differential centrifugation. The suspended virus preparations were mixed in equal volumes, layered on a 25 to 42% (W/W) sucrose gradient, and centrifuged at $110,000 \times g$ for four hr resulting in the separation of REV from RSV(RAV-2)-RSV(RAV-3). Isopycnic centrifugation in a CsCl gradient was carried out to determine whether REV has a different buoyant density than members of the avian tumor virus complex. It was found that REV had a buoyant density of 1.203 g/cm^3 whereas the RSV particles banded at a density of 1.242 g/cm^3 . The group-specific antigen of the avian tumor virus group was not detected in concentrated REV preparations disrupted by repeated freeze-thaw cycles. The results indicate that REV is not a member of the avian tumor virus complex.

3128 TEMPERATURE-DEPENDENT ALTERATIONS IN SUGAR TRANSPORT IN CELLS INFECTED BY A TEMPERATURE-SENSITIVE MUTANT OF ROUS SARCOMA VIRUS. (E.)

Martin, G. S. (Dept. Molec. Biol., U. California,

Berkeley), S. Venuta, M. Weber and H. Rubin. *Proc Nat Acad Sci USA* 68(11):2739-2741, 1971.

Chicken-embryo fibroblasts transformed by Rous sarcoma virus (RSV) take up 2-deoxyglucose at a faster rate than uninfected cells, under conditions where transformed and nontransformed cells grow at the same rate. In cells infected by a temperature-sensitive mutant, the stimulation of 2-deoxyglucose uptake is temperature dependent: the increase (3-fold higher) is observed at the permissive (36° C), but not at the nonpermissive (41.5° C) temperature. When infected cells are shifted from the nonpermissive temperature to the permissive temperature, the uptake of 2-deoxyglucose increases from a rate equal to that of uninfected cells to a rate equal to that of cells infected by the wild-type Schmidt-Ruppin Rous sarcoma virus. The reverse change occurs when the infected cells are shifted from the permissive to the nonpermissive temperature. By the use of cytosine arabinoside, an inhibitor of DNA synthesis, it was possible to show that DNA synthesis is neither required for the transformation, which occurs when the infected cells are shifted from the nonpermissive to the permissive temperature, nor for the phenotypic reversion, which occurs in the reverse shift.

3129 EFFECT OF SENDAI VIRUS INFECTION ON LIPID METABOLISM IN CHICK EMBRYO FIBROBLASTS.

(E.) Blair, C. D. (Dept. Bacteriology, Trinity Coll., Dublin, Ireland) and P. J. Brennan. *J Virol* 9(5):813-822, 1972.

Lipid metabolism in primary chick embryo cells abortively infected with Sendai virus was examined, with ³²P-orthophosphate, ¹⁴C-glucose and ¹⁴C-glycerol used as precursors. The various classes of lipids were isolated from cell extracts and identified by paper and silica gel thin-layer chromatography. Incorporation of ³²P-orthophosphate and ¹⁴C-glucose into lipids was increased between three and 24 hr after infection. Synthesis of all individual phospholipids was about equally stimulated. Evidence of increased lipid synthesis was also found in more productively-infected rhesus monkey MK cells. Although incorporation of ¹⁴C-glycerol into lipids of infected cells was increased when the precursor was present in high concentrations, incorporation of minute quantities of high-specific-activity ¹⁴C-glycerol was inhibited. This suggested that Sendai virus infection was in some way inhibiting the membrane transport process of ¹⁴C-glycerol, possibly by binding to the transport sites. Even though incorporation of radioactivity from ¹⁴C-glucose was stimulated during long labeling periods, the uptake of this precursor during short pulses was inhibited in infected cells. Results from ¹⁴C-glucose and ¹⁴C-glycerol labeling experiments indicated that when overall incorporation was inhibited in Sendai virus-infected chick embryo cells, increased triglyceride synthesis still occurred. Incorporation of ¹⁴C-glucose into nonlipid components was also stimulated in virus-infected cells, indicating that a general enhancement of metabolism had occurred.

3130 MORPHOLOGY OF TUMORS INDUCED IN HAMSTERS BY CELO VIRUS, TUMOUR TISSUE, AND TUMOUR CELLS GROWN IN CULTURE. (E.) Mancini, L. O. Dept. Animal Path., U. Rhode Island, Kingston), V. Jasty, J. Anderson and V. J. Yates. *Brit J Cancer* 26(1):28-33, 1972.

Tumors were produced in Syrian golden hamsters by s.c. inoculation of chicken-embryo-lethal-orphan (CELO) virus, by transplantation of CELO-induced tumor tissue, or by s.c. inoculation of cells cultured from CELO-induced neoplasms. Tumors were first detected three weeks to eight months post-inoculation, depending on the type of cells implanted. All tumors were fibrosarcomas which were well-circumscribed, solid and covered by a thin capsule-like structure. Histological differences were apparent among the tumors produced by the three inocula. Neoplasms induced by CELO virus were generally less differentiated and were composed of cells with polygonal or oval nuclei and indistinct cytoplasmic boundaries; numerous multinucleated, bizarre giant cells were found. Tumors produced by tumor tissue transplants were more differentiated and were composed of spindle-shaped cells with abundant collagen formation. Neoplasms induced by tumor cells grown in tissue culture were generally undifferentiated with many mitotic figures and numerous giant cells. Cells from tumors induced by CELO virus or tumor transplants produced similar morphologies when cultured *in vitro*. Cell cultures consisted of large cells with oval or rounded large nuclei and prominent nucleoli; multinucleated giant cells, cells in mitosis, and a disorganized growth pattern were also characteristic. However, mitosis and a piling-up of cells occurred more frequently in cultures derived from the CELO virus-induced tumor.

3131 RNA IN HUMAN LEUKEMIC CELLS RELATED TO THE RNA OF A MOUSE LEUKEMIA VIRUS. (E.)

Héhlmann, R. (Coll Phys. Surg., Columbia U., New York, N.Y.), D. Kufe and S. Spiegelman. *Proc Nat Acad Sci USA* 69(2):435-439, 1972.

Molecular hybridization with radioactively labeled DNA complementary to the RNA of the Rauscher leukemia virus was used to probe for homologous RNA in the polysome fraction of human leukemic cells. The leukocytes of 24 out of 27 patients examined contained RNA possessing homology to that of the mouse leukemia agent, but not to that of the unrelated viruses causing mammary tumors in mice or myeloblastosis in chickens. Further, no control human leukocytes or other adult and fetal tissues showed significant levels of the leukemia-specific RNA. It would appear that human leukemic cells contain RNA sequences homologous to those found in a viral agent known to cause leukemia in an experimental animal. The fact that human sarcomas have also been shown to contain this type of RNA points to a remarkable parallelism in the leukemias and sarcomas of mice and men.

3132 DEFICIENCY OF VIRAL RIBONUCLEIC ACID-DEPENDENT DEOXYRIBONUCLEIC ACID POLYMERASE IN NONINFECTIONOUS VIRUS-LIKE PARTICLES RELEASED FROM MURINE SARCOMA VIRUS-TRANSFORMED HAMSTER CELLS. (E.) Peebles, P. T. (Natl. Cancer Inst., Bethesda, Md.), D. K. Haapala and A. F. Gazdar. *J Virol* 9(3): 488-493, 1972.

RNA-dependent DNA polymerase activity was assayed in mouse 3T3FL cells infected with murine leukemia virus (MuLV) or with a new strain (S+H-) of murine sarcoma virus (MSV). S+H- MSV-transformed cells are MSV-positive (S+) and leukemia helper virus-negative (H-) and release noninfectious virus particles. Endogenous polymerase activity, determined by ³H-TMP incorporation in cell-free extracts, was very low in S+H--infected cells (534 cpm/90 min) compared with that of MuLV-infected cells (12,000 cpm/90 min). The synthetic RNA-DNA template poly rA·dT₍₁₂₋₁₈₎ stimulated S+H- polymerase activity only twofold, whereas MuLV enzyme activity was increased 200-fold. The noninfectious virions showed a similar lack of endogenous and poly rA·dT₍₁₂₋₁₈₎-stimulated RNA-dependent DNA polymerase activity. No inhibition of MuLV enzyme activity was found in mixtures of MuLV and S+H- MSV, indicating that the enzyme deficiency in S+H- virions was not due to an inhibitor or to a more rapid degradation of substrate, template or product. Since neither the noninfectious virions nor the S+H- MSV-infected cells had detectable replicating leukemia helper virus, it was suggested that the leukemia virus genome may be required for production of infectious sarcoma virus by contributing information needed for the full expression of functional viral-type reverse transcriptase.

3133 MALIGNANT CELL TRANSFORMATION BY THE SV-40 DNA AND PHAGOCYTIC ACTIVITY RELATED TO ALTERATION OF CELL MEMBRANES. (E.) Kimoto, T. (Osaka U. Med. Sch., Japan), E. Yokomura, K. Moriwaki and M. Yamakawa. *Acta Med Okayama* 25(1):1-12, 1970.

Cultured primary human, hamster and mouse embryo cells which were exposed to purified SV40 DNA for two hr underwent morphological transformation three months later. The transformed cells were epithelioid; multinucleated giant cells were also present. Indirect immunofluorescence revealed the presence of group-specific tumor antigen. Cells were studied for their ability to phagocytize iron chondroitin sulphate (Cs-Fe) particles. After 24 hr, none of the transformed cells showed phagocytic activity, whereas the nontransformed cells showed moderate phagocytosis. However, in the presence of arginine-rich histone at concentrations that did not affect the growth of transformed cells (100-250 µg/ml), transformed human and hamster cells actively phagocytized the Cs-Fe particles. Results of experiments in which cells were treated with various proteolytic and glycolytic enzymes indicated that substances on the cell surfaces of hamster fibroblasts were sialic acids. No difference, however, was observed between the quantity of sialic acids on normal and transformed hamster fibroblasts by electron microscopic histochemical techniques. These results indicated

that the cell membrane structures of transformants which were altered were, at least in part, those responsible for surface change; however, the alterations in phagocytic ability upon transformation were probably due to actual changes in membrane composition rather than to changes in surface coat (i.e., sialic acid).

3134 SIMIAN TUMOR VIRUS ISOLATE: DEMONSTRATION OF CYTOPATHIC EFFECTS *IN VITRO*. (E.)

Fine, D. L. (Bionetics Res. Lab., Kensington, Md.), J. C. Landon and M. T. Kubicek. *Science* 174(4007): 420-421, 1971.

Twenty-one different fetal and infant rhesus monkey and human cell lines were inoculated with Mason-Pfizer monkey virus (MPMV) and observed daily for cytopathic effect (CPE). Control cultures were inoculated with medium, without MPMV. Positive CPE's were repeatedly observed in lines from rhesus foreskin and lung and from human foreskin as early as 24 hr after inoculation with several lots of high-titered virus. CPE's were also seen 24 hr after inoculation of MPMV-infected NC37 cells onto fetal foreskin and lung cell monolayers and six days after inoculation onto tooth bud and heart cell cultures. CPE's were characterized by multinucleated cells containing as many as 18 nuclei, which were generally clustered within the affected cells and surrounded by a large cytoplasmic area. Electron microscopic observation showed the presence of intranuclear, electron-dense, ring-shaped, 81- to 85-nm particles in the infected cells. Examination of purified virus-pellet sections showed similar structures. Twenty-four to 48 hr after infection with one lot of high-titered MPMV, cultures showed areas of clustered, rounded cells, loosely adhering to the culture surface. This change appeared to be associated with a proliferative cellular response.

3135 MURINE SARCOMA AND LEUKEMIA VIRUSES: GENETIC DIFFERENCES DETERMINED BY RNA-DNA HYBRIDIZATION. (E.) Stephenson, J. R. (Natl. Cancer Inst., Bethesda, Md.) and S. A. Anderson. *Virology* 46(2):480-484, 1971.

A relative measure of the genetic information of the Kirsten strains of murine sarcoma virus, KiMSV (KiMuLV), and murine leukemia virus (KiMuLV) is obtained by comparing the ability of *in vitro* DNA products to hybridize with 60-70S viral DNA. KiMuLV and KiMSV (KiMuLV) *in vitro* DNA products were made, and ³²P-labeled 70S RNA was prepared from the supernatant fractions of infected cultures. To determine whether DNA preparations were complementary to the majority of their respective 70S RNA, 70S KiMSV (KiMuLV) RNA was hybridized with its homologous *in vitro* DNA product (0.1-0.2 µg.) resulting in up to 80% protection of the viral RNA from RNase digestion. Similar results were obtained using KiMuLV, ruling out the possibility of preferential transcription of either the sarcoma or leukemia genetic information during *in vitro* DNA synthesis.

3136 INHIBITORY EFFECT OF RIFAMPICIN ON RAUSCHER-VIRUS-INDUCED MURINE LEUKAEMIA. (E.)

Gielkens, A. L. J. (Dept. Biochem., U. Nijmegen, Netherlands), J. Th. M. Burghouts and H. Bloemendal. *Int J Cancer* 9(3):595-598, 1972.

Three-week-old random-bred female Swiss mice who were given i.p. injections of a homogenate of Rauscher virus-induced leukemic spleen, were then given daily oral doses of rifampicin mixed with food, beginning at different times and continued until the 28th day after infection. The animals were then sacrificed and their spleens were weighed. Administration of 5 mg rifampicin/day, starting on day 7, resulted in a 62% reduction of spleen enlargement. Inhibition was greatest (90%) when rifampicin administration was started immediately after infection. Pretreatment of mice with rifampicin for seven days prior to virus infection did not enhance its inhibitory effect. The inhibitory effect of rifampicin was dose-dependent. A single dose of 1250 mg/kg body weight of rifampicin, administered on day 7, was not lethal. It is suggested that rifampicin was more toxic to transformed than to normal cells and that these results might have important implications for a rational leukemia therapy.

3137 MORPHOLOGICAL AND BIOPHYSICAL PROPERTIES OF THE MASON-PFIZER MONKEY VIRUS. (E.)

Manning, J. S. (Sch. Public Hlth., U. California, Berkeley) and A. J. Hackett. *J Nat Cancer Inst* 48(2):417-422, 1972.

Mason-Pfizer monkey virus (M-PMV) was characterized in a line of rhesus monkey embryonic lung cells infected with a cell-free filtrate from a mammary carcinoma cultured from another rhesus monkey (designated MEL III). With one exception, electron microscopy of MEL III cell pellets failed to show the presence of virus particles budding from the cell membrane. Inter-cellular A-type particles were not detected. Numerous virus particles, however, were detected in cell-free extracellular fluid after precipitation with cold saturated ammonium sulfate. Enveloped virus particles had a diameter of 110 mμ. Most virions had a condensed, eccentrically located nucleoid. Several particles contained a distinct intermediate membrane surrounding the nucleoid. Spikelike surface projections were not detected on virus particles. Centrifugation of tissue fluids pre-labeled with ³H-uridine for 16 hr in sucrose gradients led to the formation of a single sharp zone of acid-insoluble material with a peak density of 1.55 g/ml. Incorporation of ³H-uridine into these virus particles was inhibited by 0.05 μg/ml actinomycin D. Cosedimentation with 18S and 28S marker, after extraction with 1% SDS and pronase, indicated a sedimentation coefficient of approximately 65S for M-PMV RNA. Polyacrylamide gel electrophoresis of M-PMV RNA indicated a molecular weight of approximately 7x10⁶ daltons. Several independent lines of evidence indicated that the cultures were free of simian foamy virus. Sucrose density gradient analysis of cell-free fluids from chimpanzee lung cells previously cocultivated with MEL III cells or

with cell-free fluids from MEL III cells showed that virus had been transmitted to the chimpanzee cells.

3138 SV40-INDUCED TRANSFORMATION OF CELLS OF THE LIZARD *GEKKO GEKKO*. (E.) Clark, H. F.

(Wistar Inst. Anatomy Biol., Philadelphia, Pa.), F. Jensen and V. Defendi. *Int J Cancer* 9(3):599-607, 1972.

Attempts to infect four cell lines of reptilian origin, GL1 (*Gekko gekko*), IgH-2 (*Iguana iguana*) and VH2 and VSW (both *Vipera russelli*), with SV40 strain RH911 led to successful infection of only the lizard line, GL1. SV40 infection was determined by the appearance of persisting T antigen in 100% of the cell population (as shown by indirect immunofluorescence) and was obtained in cells inoculated and maintained at 23, 30 or 35 C (GL1 cells grown optimally at 30 C). In early passages, infected GL1 cells exhibited a more orderly growth pattern and a more uniform cell morphology than did uninfected control cells. However, at about the 50th passage level after infection, a more exuberant growth pattern developed, characterized by cell saturation densities exceeding those of control cell cultures by approximately threefold. Infectious virus in low titer was recovered from the cells and media of infected cell lines tested during the first 21 passages after infection. At subsequent passage levels, virus could be rescued from cells maintained at 23, 30 or 35 C only by cocultivation with African green monkey kidney (AGMK) cells. The presence of SV40 tumor-specific transplantation antigen was demonstrated by experiments in which hamsters inoculated with infected GL1 cells received marked protection against SV40 tumor induction. The SV40-infected cells showed increased resistance to inhibition of cell growth by dextran sulfate and an enhanced ability to multiply at supraoptimal temperatures. The viral transformation of the poikilothermic GL1 cells represents a considerable phylogenetic extension of the range of host cells known to be transformable by SV40.

3139 THE SECONDARY STRUCTURE OF REPLICATING POLYOMA VIRUS DNA. (E.) Bourgaux-Ramoisy, D.

(U. Hosp. Ctr., U. Sherbrooke, Quebec, Canada). *Biochim Biophys Acta* 254(3):412-414, 1971.

The replicative intermediate of polyoma virus DNA, referred to as II*, consists of both double- and single-stranded portions. To analyze the extent of each portion, polyoma virus DNA was extracted from infected mouse embryo cells, labeled with tritiated thymidine, and extensively sonicated. The DNA fragments were eluted, first with saline to isolate the mature double-stranded fragments, and then with a saline-caffeine solution to isolate the single-stranded parts. Each elution was then treated with nuclease. Nuclease treatment did not result in any reduction of the acid-precipitable radioactivity present in the saline fraction, while it did result

In a 10% reduction of tritium counts in the caffeine fraction. It is concluded that the single-stranded regions of DNA II* are, at most, 1 to 2% of its length, or approximately 200 nucleotides; this material might be part of the growing points.

3140 PATTERN OF PROTEIN SYNTHESIS IN MONKEY CELLS INFECTED BY SIMIAN VIRUS 40. (E.) Anderson, C. W. (Cold Spring Harbor Lab., New York) and R. F. Gesteland. *J Virol* 9(5):758-765, 1972.

The pattern of protein synthesis in permanent monkey cell lines (CV-1, BSC-1 and MA-134) infected with simian virus 40 (SV40) was analyzed by SDS-polyacrylamide gel electrophoresis of ³⁵S-methionine-labeled extracts. During the first 15 hr after SV40 infection, very little change was seen in protein patterns. Between 15 and 18 hr after infection, a new band (IVP1) appeared which co-migrated with the major capsid protein from purified SV40 (VP1; 43,000 daltons). Three hr later, two more virus-specific bands appeared. One (IVP3) co-migrated with the minor capsid protein, VP3. The second (IVP3.5) migrated between the VP3 and VP4 marker proteins (m.w.=15,000 daltons) and did not correspond to any of the six virion capsid proteins previously reported. The non-capsid protein band (IVP3.5) was induced in the CV-1 and BSC-1 but not the MA-134 cultures by SV40 infection. A fourth virus-induced protein (IVP2; 32,000 daltons) was observed 24 hr after infection. All four proteins appeared to be synthesized at increasing rates as infection progressed. Experiments using inhibitors of SV40 DNA synthesis (ara-C and FUDR) showed that production of all four virus-induced proteins was dependent upon viral DNA synthesis (identified by neutral and alkaline gradient centrifugation with labeled SV40 DNA as marker).

3141 CELL-DEPENDENT DIFFERENCES IN THE PRODUCTION OF INFECTIONOUS HERPES SIMPLEX VIRUS AT A SUPRAOPTIMAL TEMPERATURE. (E.) Crouch, N. A., Milton S. Hershey Med. Ctr., Pennsylvania St. U., (Hershey) and F. Rapp. *J Virol* 9(2):223-230, 1972.

The replication of herpes simplex virus (HSV) was compared in rabbit and hamster cells at optimal and supraoptimal temperatures. Replication occurred in cells of either species at 33 C, but the total infectious virus yield was routinely about tenfold greater in rabbit cells than in hamster cells. At 39 C, this difference was exaggerated to greater than 100,000-fold. Whereas infectious virus was produced and plaques formed in rabbit kidney cell monolayers at the higher temperature, neither developed in those derived from hamster embryos. Elevating the temperature from 33 C to 39 C at various time intervals after exposure of the cultures to virus revealed that production of infectious virus in hamster cells was completely heat-sensitive up to six hr after infection. Specific viral antigens and viral deoxyribonucleic acid (DNA) were

synthesized in both rabbit and hamster cell cultures. In addition, cellular DNA synthesis was depressed and cytopathic effects occurred in both cell systems. These cytopathic effects were not observed in cell cultures treated with HSV previously inactivated with ultraviolet light. Compared with parallel cultures at 33 C, the amount of viral DNA synthesized at 39 C was greatly reduced in both systems. In hamster cells, the reduction was two-fold greater than in rabbit cells. This cell-dependent thermal inhibition of HSV replication in hamster cells did not occur with vaccinia virus.

3142 ELECTRON MICROSCOPE STUDY OF A BALB/c LEUKEMIA VIRUS IN CELL CULTURE SYSTEMS. (E.) Lambertenghi, G. (Sloan-Kettering Inst. Cancer Res., New York, N.Y.), E. de Harven, T. Sato and J. R. Tennant. *Cancer Res* 32(6):1108-1116, 1972.

B/T-L virus, a BALB/c leukemia virus member of the MuLV group, was grown in two cell lines (A and D) originating from normal, infant BALB/c thymus tissue. Cell pellets from lines A (epithelioid) and D (fibroblastic), observed under the electron microscope, showed large numbers of virus particles, mostly C-type, within the extracellular spaces or in contact with the cell surfaces. Cells from old (10-21 days after seeding) confluent monolayer cultures practically never showed budding virus; however, budding viruses were readily observed in all young cultures (2-3 days after seeding). The level of phagocytosis of viral particles, evaluated by the number of phagolysosomes containing viruses, was high in the D cells, but rare in the A line cells. Structurally damaged C-type particles were frequently recognized within phagolysosomes. The membranes limiting the phagolysosomes showed no continuity with other recognizable cytoplasmic organelles and apparently never participated in virus budding. Virus phagocytosis in D line cells was also demonstrated by the combined methods of ferritin tracing, lanthanum staining and acid phosphatase localization. The phagolysosomes could clearly be distinguished from other virus-containing cytoplasmic vacuolar structures which were limited by membranes along which virus budding could be seen.

3143 RESTRICTION BY POLYCATIONS OF INFECTION WITH MYXOMA VIRUS IN RABBITS. (E.)

Wegner, D. L. (Dept. Med. Microbiol., U. Wisconsin, Madison) and H. C. Hinze. *J Infect Dis* 125(2):141-145, 1972.

The effect of polycations on progressive infection of New Zealand white rabbit myxoma virus was studied. Intradermal injection of a mixture of 50 pfu of virus and 9 mg of the polycations, DEAE-dextran, polyornithine, polylysine, produced slightly raised, circular lesions at the injection site but did not cause secondary lesions or other symptoms of systemic disease. All control animals injected with virus in balanced saline followed the classic clinical progression of myxomatosis. In contrast,

weanlings receiving this dose, or adults receiving a larger dose of virus (3×10^5 pfu mixed with 9 mg DEAE-dextran) were not protected from systemic myxomatosis. Administration of DEAE-dextran into the inoculation site either before or after virus infection, or systemic (i.v. or i.p.) inoculation also did not protect animals from progressive disease. DEAE-dextran, when mixed with the related Shope rabbit-fibroma virus and injected intradermally into rabbits, resulted in reduced size of virus induced tumors compared with controls. DEAE-dextran had no effect on the outcome of disease caused by the unrelated pseudorabies virus. The inability of dextran and dextran sulfate to prevent systemic myxomatosis suggests that positive charge, rather than the nature of the molecular backbone, is important in the inhibitory process. Treatment with DEAE-dextran slowed down myxoma virus multiplication and inhibited viremia in infected animals. DEAE-dextran had no enhancing influence on immune response in infected rabbits.

3144 CHROMATOGRAPHIC SEPARATION AND ANTIGENIC ANALYSIS OF PROTEINS OF THE ONCORNAVIRUSES: II. MAMMALIAN LEUKEMIA-SARCOMA VIRUSES. (E.)

Nowinski, R. C. (Sloan-Kettering Inst. Cancer Res., New York, N.Y.), E. Fleissner, N. H. Sarkar and T. Aoki. *J Virol* 9(2):359-366, 1972.

Isotopically prelabeled proteins of leukemia and sarcoma viruses from chicken (AvLV), mouse (MuLV), hamster (HaSV), and cat (FeLV) were analyzed by gel filtration in guanidine hydrochloride. The mammalian viruses contained six major proteins, two of which (m1 and m2) were glycoproteins as judged by their ability to incorporate ^3H -glucosamine. Avian viruses contained seven major proteins. Viral proteins from the different mammalian species had the same molecular wt which also closely resembled the molecular wt of the six equivalent avian viral proteins. Thus, a basic similarity in protein composition was demonstrated between the C-type viruses of avian and mammalian origin. The two glycoproteins (m1 and m2) of murine leukemia virus (MuLV) were identified by "immune electron microscopy" and by indirect immunofluorescence (IF) as constituents of the viral membrane. Antisera prepared against other proteins distinguished individual internal viral antigens in immunodiffusion tests and also reacted in IF with cytoplasmic components of infected cells. Antisera which reacted with the major internal viral proteins did not contain antibodies inhibitory to the viral reverse transcriptase.

- 3156 NONSPECIFIC STIMULATION OF TUMOR-ASSOCIATED IMMUNITY BY METHANOL-SOLUBLE FRACTION OF *MYCOBACTERIUM BUTYRICUM*. (E.) Esber, H. J. (Mason Res. Inst., Worcester, Mass.) F. F. Menninger, Jr., D. J. Taylor and A. E. Bogden. *Cancer Res* 32(4): 795-803, 1972.

Methanol-soluble fractions of *Mycobacterium butyricum* (MSF-MB) were prepared and injected i.p. into rats in amounts of 0.625 to 40 mg/rat at intervals from 21 days before to four days after injection with sheep erythrocytes (SRBC). The heteroantibody response of rats to SRBC, as modified by MSF-MB, was observed in rats bled at seven, 14, 21 or 28 days post-SRBC. MSF-MB induced a significant enhancement of antibody response to SRBC; the antibody response paralleled MSF-MB dose increase, reaching maximal levels at 10 mg/rat. Optimal enhancement of the antibody response was seen when this dose of MSF-MB was given ten days before SRBC. When MSF-MB was given seven days before SRBC, peak enhancement of the antibody response was seen seven days post-SRBC. When MSF-MB was given simultaneously with, or two to four days after SRBC, peak antibody response was seen on day 14 post-SRBC. The antibody response in MSF-MB-treated rats persisted at high levels for 28 days post-SRBC. Rats bearing grafted mammary adenocarcinomas (13762 and R-35), squamous prostatic carcinomas (11095), or acute monocytic leukemia (R3149), showed a suppressed heteroantibody response to SRBC when tumor-bearing rats were challenged with SRBC during the early or midlog phases of tumor growth. MSF-MB not only abrogated the immunosuppressive effect of grafted 13762 mammary adenocarcinoma and 11095 prostatic carcinoma, but also significantly enhanced the heteroantibody response to SRBC in rats bearing the R-35 mammary tumor or the R3149 leukemia.

- 3157 THE AUSTRALIA ANTIGEN IN AFRICANS FROM DAKAR WITH CIRRHOSIS AND PRIMARY CANCER OF THE LIVER. (Fr.) Sankale, M. (Joint Fac. Med. Pharmacy, Dakar, Senegal), I. Seck, J. Linhard, A.-A. Thiam, A.-B. Wane, G. Diebolt and A. Poll-Gouater. *Bull Soc Med Afr Noire Lang Franc* 16(2): 167-171, 1971.

Ouchterlony's immunodiffusion method was used to test 955 sera from African patients hospitalized at a Dakar hospital for the presence of the Au-1 antigen and its corresponding antibody. These patients included 45 with cirrhosis and 64 with primary liver cancer. Of these 955 sera, 110 (11.5%) were positive for Au-1 and 4 (0.4%) were positive for anti-Au-1. Au-1 antigen was found in 27 of the 64 patients with liver cancer (42.4%), in 11 of the 45 cirrhotics (24.5%), and in 72 of the remaining patients (8.5%). A previous study showed that only 2% of Dakar blood donors had Au-1 antigen and none had the corresponding antibody. Therefore, it is concluded that the Australia antigen is significantly more common among patients with cirrhosis and primary liver cancer than it is in the general population. The incidence of the antigen is significantly higher among liver cancer patients than among cirrhotics.

- 3158 AUTOIMMUNE-LIKE ANTIBODIES TO THE LIGAND-BINDING SITES OF MYELOMA PROTEINS. (E.) Sirisinha, S. (Washington U. Sch. Med., St. Louis, Missouri) and H. N. Eisen. *Proc Natl Acad Sci USA* 68(12):3130-3135, 1971.

BALB/c mice were immunized with three A-myeloma proteins of BALB/c-2 or BALB/c origin (produced by plasmacytomas MOPC-315, MOPC-460, Adj. PC-22A). Non cross-reacting antibodies were formed against Proteins-315 and 460, but the response to Protein-22A was marginal. Proteins-315 and 460 have anti-dinitrophenyl activity, and their reactions with the corresponding BALB/c antibodies were inhibited by dinitrophenyl ligands. It appears that antibodies can be formed in BALB/c mice against unique "idiotypic" determinants in the ligand-binding sites of some BALB/c myeloma proteins.

- 3159 CENTRAL INHIBITION OF CELLULAR IMMUNITY TO LEUKEMIA L1210 BY ISOANTIBODY. (E.) Mitchell, M. S. (Yale U. Sch. Med., New Haven, Conn.). *Cancer Res* 32(4):825-831, 1972.

Four injections of 0.1 ml hyperimmune antibody (Ab) to leukemia L1210 were given to C57BL/6J (C57) mice before or after challenge with viable L1210 cells. Ab consisted of antibody-rich ascitic fluid from C57 mice immunized with repeated injections of L1210 cells. Cellular immunity of AB-treated mice to L1210 cells was measured *in vitro* by observing the ability of their spleen cells to lyse cells of a mastocytoma line. Ab given one to four days before L1210 challenge completely suppressed spleen cell-mediated immunity; spleen cells of mice not given Ab and challenged with L1210 lysed 93-96% of mastocytoma cells, while spleen cells from Ab-treated mice failed to lyse any mastocytoma cells. Ab given one to four days after L1210 cells was relatively ineffective in suppressing immunity. The inhibitory effect of Ab was limited to cellular immunity; formation of isohemagglutinins and cytotoxic antibodies in Ab-treated mice was usually unaffected. The number of L1210 cells was reduced considerably in challenged mice given Ab before or after challenge. The reduced number of tumor cells did not entirely explain the decrease in cellular immunity, however. Pretreatment of mice spleen cells with Ab *in vivo* or *in vitro* before injection into lethally irradiated mice prevented development of cellular immunity to a challenge with L1210 cells. Normal bone marrow cells, injected with Ab-treated spleen cells, partially repleted immunity in irradiated recipients. When the IgG and IgM fractions of Ab were injected separately into recipients prior to L1210 challenge, it was found that the inhibition of immunity achieved by whole Ab was duplicated by its IgG fraction.

- 3160 MEDIATION OF IMMUNITY TO TUMOR-SPECIFIC TRANSPLANTATION ANTIGENS BY RNA INHIBITION OF ISOGRAFT GROWTH IN RATS. (E.) Deckers, P. J.

tl. Cancer Inst., Bethesda, Md.) and Y. H. Pilch. *Cancer Res* 32(4):839-846, 1972.

cher 344/N rats were inoculated s.c. with 10^5 ble cells of a benzo(a)pyrene-induced sarcoma (BP-1R); when palpable tumors appeared they were used to render rats immune to BP-1R. While 90% rats which were not thus immunized developed tumors after challenge with 10^5 BP-1R cells, all immunized rats rejected challenge BP-1R isografts. A study of the adoptive transfer of immunity to BP-1R, rats were inoculated with BP-1R, tumor-bearing rats were amputated, and amputees were challenged with BP-1R cells and found to be immune to BP-1R isografts. Immune rats were given additional inocula of BP-1R cells, and killed; spleens were removed and suspensions of spleen cells from immune rats and from rats not immunized by amputation of sarcoma-bearing limbs were injected into normal recipients. Recipients were challenged with BP-1R cells, those given immune spleen cells resisted the challenge isograft, while those given spleen cells from non-immune rats were not resistant. In related experiments, rats were immunized to BP-1R by amputation of sarcoma-bearing limbs after tumor cell inoculation. Immunized rats were given three doses of BP-1R cells and killed. Spleen cells from non-immune rats were incubated with RNA from immune rats' spleen cells and injected into recipients which were later given challenge inocula of BP-1R cells. The growth of sarcomas arising in rats immunized with spleen cells treated with immune rats' RNA was retarded as compared to tumor growth in rats given spleen cells preincubated with RNA from an unimmunized rat spleen, or in rats given non-treated spleen cells. When BP-1R isografts were inoculated together with the first of three injections of spleen cells incubated with immune rats' RNA, the incidence of development of tumor isografts was reduced as compared to the incidence in recipients of untreated spleen cells. When immune RNA preparations were treated with RNase before incubation with rat spleen cells, the ability of this RNA to inhibit tumor isograft growth and development was abolished.

IMMUNOTHERAPY OF FRIEND DISEASE IN MICE EMPLOYING VIABLE BCG VACCINE. (E.)

on, C. L. (Dept. Microbiol., U. Montana, Missoula), R. E. Baker, R. N. Ushijima, M. B. R and C. Gillespie. *Proc Soc Exp Biol Med* 140:700-702, 1972.

Effect of administration of *Mycobacterium bovis* BCG to Friend's disease virus (FDV)-infected mice was studied. Animals treated by i.v. injection of BCG vaccine (4×10^6 U) three wk after infection with FDV had an increased survival time compared to unimmunized, infected mice. The survival rate at 1 wk after challenge with FDV was 29% (8 of 27) in infected unimmunized mice and 67% (14 of 21) for infected immunized animals. In a second series of experiments, FDV-infected mice were vaccinated i.v. with BCG after seven days and again s.c. on days 14

and 21. The spleens of all mice were examined after 28 days. Spleens of infected unvaccinated mice were greatly enlarged compared to those of normal control mice, but the spleens of infected vaccinated mice were only slightly larger than those of vaccinated uninfected controls. FDV plaque counts were fewer in spleens of vaccinated mice than in those of unvaccinated animals. Infected vaccinated animals took 6-8 wk longer than unvaccinated infected mice to attain a 50% mortality rate.

3162 IMMUNOLOGICAL STUDIES ON URINARY BLADDER TUMORS OF RATS AND MICE. (E.) Taranger,

L. A. (U. Washington Med. Sch., Seattle), W. H. Chapman, I. Hellström and K. E. Hellström. *Science* 176(4041):1337-1340, 1972.

Bladder carcinomas and papillomas induced by implantation of 3-methylcholanthrene (MC) pellets into inbred BALB/c mice and Fischer rats were tested by an *in vitro* microcytotoxicity assay for the presence of tissue type specific (TTS) antigens. TTS antigens were demonstrated to be associated with different bladder papillomas and carcinomas of rats and to be associated with bladder carcinomas of mice. Lymph node cells (LNC) from animals sensitized against sarcomas were not cytotoxic to cultured bladder carcinoma cells but did destroy sarcoma target cells under similar conditions. Likewise, LNC from animals bearing bladder tumors were not cytotoxic to cultured sarcoma cells but were able to destroy cells cultured from bladder carcinomas and papillomas. Preimmunization of rats by injection of a crude suspension of rat papilloma cells combined with either Waymouth's medium or Freund's complete adjuvant suppressed tumor growth *in vivo* compared with unimmunized controls ($P < 0.005$) 4.5 months after bladder implantation of MC pellets. The difference between the experimental and control groups was not significant 6.5 months after insertion of MC pellets. The demonstration of common antigens in chemically induced bladder papillomas and carcinomas was at variance with most findings made on chemically induced murine sarcomas and hepatomas. It did, however, agree with observations made on human neoplasms and may thus provide a better system for the study of the human problem than animal tumors previously studied.

3163 COMPLEMENT-FIXING ANTIMOUSE ANTIBODIES FOUND IN MICE AFTER INOCULATION OF BRAIN, FREUND'S COMPLETE ADJUVANT, AND SARCOMA 180/TG CELLS. (E.) Berman, R. S. (Yale U. Sch. Med., New Haven, Conn.) and R. E. Shope. *Proc Soc Exp Biol Med* 138(3):936-938, 1971.

Female Swiss ICR/KP mice were immunized with mouse brain cells and/or Freund's complete adjuvant (FCA), or with sarcoma 180/TG (S-180/TG) cells plus mouse brain and FCA. Ascitic fluids from immunized mice were harvested by paracentesis and reacted in com-

plement fixation (CF) tests against brain cell preparations from apparently normal mice (MB). In mice given S-180/TG cells, CF antibodies to MB were not detected in ascites fluid collected ten days after immunization, but were detected in fluid taken on day 16. On day 16, 25% of mice given mouse brain and FCA together with S-180/TG cells showed anti-MB CF activity, while 8% of mice given S-180/TG only, and 2% of mice given mouse brain and FCA, showed CF antibody. Antimouse CF antibody was minimal in ascitic fluids of mice given FCA and egg and bovine albumin.

- 3164 MECHANISMS INVOLVED IN THE ANTILEUKEMIC EFFECT OF IMMUNOCOMPETENT ALLOGENEIC LYMPHOID CELL TRANSFER. (E.) Ellman, L. (Nat'l. Inst. Allergy Infect. Dis., Bethesda, Md.), D. H. Katz, I. Green, W. E. Paul and B. Benacerraf. *Cancer Res* 32(1):141-148, 1972.

A marked prolongation of survival time was attained in a group of strain 2 guinea pigs that had received allogeneic strain 13 lymphoid cells six days prior to challenge with L₂C leukemia. The protection resulted from the development of the graft-versus-host reaction, as evidenced by the failure to observe such protection in strain 2 recipients of semisyngeneic 2 x 13 F₁ hybrid donor cells. The capacity to protect against leukemia by passive transfer of parental strain 2 or strain 13 lymphoid cells in 2 x 13 F₁ recipients shows that the concomitant existence of a host response is not required. The possibility that donor cells reject L₂C leukemia on the basis of an immune response directed against strain 2 histocompatibility antigens present on L₂C cells is definitely excluded: Strain 2 parental cells were equivalent to strain 13 cells in affording protection to F₁ recipients. Immunocompetent lymphoid cells appear to exert the primary effector mechanism in the protection phenomenon. The potential promise of allogeneic cell transfers as an approach to immunotherapy of human cancers is considered.

- 3165 EFFECT OF SERA FROM PATIENTS WITH HODGKIN'S DISEASE ON NORMAL LYMPHOCYTE RESPONSE TO PHYTOHEMAGGLUTININ. (E.) Han, T. (Roswell Park Mem. Inst., Buffalo, N.Y.). *Cancer* 29(6):1626-1631, 1972.

Sera from 63 patients with histologically diagnosed Hodgkin's disease were tested for their effect on phytohemagglutinin (PHA) stimulation of lymphocytes from healthy donors. Sera from patients in remission generally had no effect on PHA stimulation of normal lymphocytes when compared with the effect of sera from healthy donors. Sera from some patients with symptomatic disease inhibited the response of normal lymphocytes to PHA stimulation. This inhibitory effect was greatest with serum from patients receiving prednisone (30-40 mg/day) therapy. The inhibition was apparently due to the effects of treatment, since the responses in sera from seven

untreated patients with systemic symptoms were not different from those in normal sera. An apparent stimulation of PHA response was seen with sera from a group of patients with active disease of the mixed cellularity type. Results using Hodgkin's sera were not consistently reproducible. For example, initially, sera from five remission patients stimulated the PHA response of normal lymphocytes; however, when they were retested, no stimulatory effect was observed.

- 3166 HEPATITIS-ASSOCIATED ANTIGEN AND ANTIBODY IN HEPATOCELLULAR CARCINOMA: RESULTS OF A CONTINUING STUDY. (E.) Vogel, C. L. (Uganda Cancer Inst., Kampala), P. P. Anthony, F. Sadikali, L. F. Barker and M. R. Peterson. *J Nat Cancer Inst* 48(6):1583-1588, 1972.

Sera from 90 Ugandan hepatocellular carcinoma patients and from 224 controls were tested for hepatitis-associated antigen (HAA) by counterelectrophoresis (CEP) and complement fixation and for antibody to HAA by CEP and passive hemagglutination. Patients and controls did not differ significantly with regard to the presence of anti-HAA; however, they did differ significantly with regard to the frequency of HAA as 36 of 90 (40%) patients were HAA positive as opposed to only 7 of 224 (3%) controls. No significant differences due to sex or age were found for the distribution of anti-HAA. However, HAA frequency decreased with increasing age. Alpha fetoprotein (AFP)-positive patients with hepatocellular carcinoma were HAA positive significantly ($P < 0.05$) more often (47%) than AFP-negative patients (15%). HAA frequency did not differ significantly between patients whose tumors were superimposed on cirrhotic versus noncirrhotic liver tissue. In the present series, all but one of the patients with hepatocellular carcinoma had macronodular cirrhosis.

- 3167 STUDY OF COMPLEMENT-FIXING ANTIBODY TO THE THERMOSTABLE COMPONENT OF T-ANTIGEN OF ADENOVIRUS TYPE 12 IN THE BLOOD SERUM OF CANCER PATIENTS. (Rus.) Degtyarenko, V. I. (I. I. Mechnikov Res. Inst. Virol. Epidemiol., Odessa, USSR), N. I. Zatsepin, T. M. Rybakova, L. A. Vasyutinskaya, V. D. Dragomeretskii and O. V. Dyumin. *Vop Virusol* 16(4):451-455:1971.

Complement-fixing (CF) antibodies to the thermostable component of T-antigen of hamster tumors induced by adenovirus type 12 were assayed by Selivanov's complement-fixation method in sera from patients with malignant neoplasms, normal subjects, and patients with somatic and infectious diseases. Before the test, sera were heated to 56 C for 30 min to remove thermolabile inhibitors. T-antigen antibodies were most frequently found in sera of cancer patients (167/268 or 62.3%). They occurred less frequently in sera from patients with somatic diseases (atherosclerosis, hypertension, cholecystitis, etc.) (57/238 or 23.9%), infectious diseases (24/110 or 21.8%), and normal subjects (18/180 or 10%). The titers of

F antibodies to the thermostable component of T-antigen fluctuated from 1:4 to 1:128. The highest titers were found in sera from patients with malignant neoplasms of the mammary gland (25/41), larynx and oral cavity (17/28), uterus and adnexa (16/27), skin (6/12), and in sera from patients with mammary fibroadenoma and mastopathy (19/28). Mean titers were highest in sera from patients with cancer. The Ouchterlony test with concentrated adenovirus antigen for serotype 6 gave completely different results. The mean titer for precipitating antibodies in sera from cancer patients was lower ($1:1.20 \pm 0.08$) than in sera from normal subjects ($1:2.6 \pm 0.11$). The frequency with which precipitating antibodies were detected was low in cancer patients (130/321 or 40.5%) and high in normal subjects (107/152 or 67.1%). Antigen to the thermostable component of T-antigen from hamster tumors induced by human adenovirus type 12 in sera from cancer patients indicates that the genome of onco-genic adenovirus type 12 is integrated in the epithelial tissue.

68 IMMUNOGLOBULIN G AND FREE KAPPA-CHAIN SYNTHESIS IN DIFFERENT CLONES OF A HYBRID CELL LINE. (E.) Mohit, B. (Nat'l. Inst. Hlth., Bethesda, Md.). *Proc Nat Acad Sci USA* 68(12):3045-3048, 1971.

clonal cell lines were isolated from a hybrid cell population established by cell fusion between cloned ELB/c myeloma cells that were resistant to 8-azaguanine and produced immunoglobulin G and free kappa chain and C57BL/6n lymphoma cells that were resistant to bromodeoxyuridine and did not produce immunoglobulins. Some of the histocompatibility-2 antigens of both parental cell lines could be demonstrated on all the hybrid clones. Eleven clones synthesized only free kappa chain. Two clones synthesized IgG of ELB/c type, as well as free kappa chain. These clones had higher chromosome number than did the clones that synthesized only kappa chains.

359 SPECIFIC DESENSITIZATION OF RESISTANCE AGAINST A SYNGENEIC METHYLCHOLANTHRENE-INDUCED SARCOMA IN C3Hf MICE. (E.) Vaage, J. (U. of Oslo M.D. Anderson Hosp. Tumor Inst., Houston). *Cancer Res* 32(2):193-199, 1972.

C3Hf/Bu female mice were given sensitizing s.c. implants of living pieces of methylcholanthrene-induced fibrosarcoma or of an unrelated mammary carcinoma. Implanted tumors were removed on consecutive days from four days before to four days after challenge of tumor-sensitized mice with s.c. injections of viable fibrosarcoma cells. Mice whose sensitizing implants had been removed before challenge were completely resistant to challenge; mice from which implants were removed after challenge were less resistant than the others, but more resistant than control mice not given sensitizing implants. The presence or absence of mammary carcinoma at the time of challenge did not affect resistance to the fibrosarcoma. In a

related experiment, mice were sensitized with s.c. implants of the fibrosarcoma; implants were removed four days before tumor cell challenge. Other mice were sensitized with three injections of irradiation-killed fibrosarcoma cells; injections were given from six days before challenge to 12 days after challenge. Injection of killed fibrosarcoma cells decreased resistance of hosts and aided the implantation of challenge tumor cells when injections occurred during the week following challenge. Injections occurring before or after this week did not affect host resistance to challenge. Injections of killed mammary carcinoma cells did not affect resistance. The presence of the sensitizing fibrosarcoma implant until four days after challenge significantly reduced resistance to tumor cell challenge. In a third experiment, mice were sensitized with s.c. implants of fibrosarcoma tissue and implants were removed four days before challenge implantation of fibrosarcoma tissue. Mice were then given injections of irradiation-killed fibrosarcoma cells containing 50 mg to 1 μ g of cells; these injections were given four days before challenge, with challenge, or four days after challenge. Three injections of fibrosarcoma cells in doses of from 50 mg to 50 μ g each depressed resistance to challenge; doses of from 10-1 μ g did not affect resistance. In a final experiment the effect on host resistance of sensitizing implants of different sizes was tested. Resistance to challenge was not affected by small (6 x 6 mm) tumor implants left *in situ* after challenge, while large (13 x 13 mm) tumor implants markedly reduced resistance. Serum factors were apparently not responsible for depression of host resistance to challenge by antigenic tumor tissue; specific desensitization of host resistance factors, rather than immunological enhancement, seemed to be implicated in the depression of resistance.

3170 TUMOR-SPECIFIC ANTIGENS ASSOCIATED WITH AMINOAZO DYE-INDUCED RAT HEPATOMAS. (E.) Baldwin, R. W. (Cancer Campaign Res. Lab., U. Nottingham, England), D. Graves, J. R. Harris and M. R. Price. *Transplantation Proc* 3(3):1189-1191, 1971.

Aminoazo dye-induced rat hepatomas have at least two groups of cell surface antigens which differ from those expressed on normal liver cells; the tumor-specific antigen and the embryonic-type antigen. Embryonic antigens have been demonstrated by direct immunofluorescence on the surface of rat hepatomas by reaction of suspended viable tumor cells with sera from immune multiparous female rats. Most sera reacted with cells of more than one tumor, including those induced by carcinogens other than aminoazo dyes, suggesting that embryonic antigens are common tumor components. Tumor-specific antigens, however, do not show the property of cross-reaction found with the embryonic-type antigens. The membrane-bound tumor-specific antigens may be removed or inactivated by limited papain digestion, or short-term (30 min) lipase or β -glucosidase treatment. The association between membrane and tumor-specific

antigen is apparently specific for the glycoprotein and lipid components, as treatment with α -glucosidase, β -galactosidase, hyaluronidase, neuraminidase or ficin fails to affect surface expressed antigen.

- 3171 IMMUNOFLUORESCENT ASSAY OF HERPESVIRUS TYPE 1 AND TYPE 2 ANTIBODIES IN RABBIT AND HUMAN SERA. (E.) Leinikki, P. (Dept. Virology, U. Helsinki, Finland). *Arch Ges Virusforsch* 35(4): 349-355, 1971.

Three groups of patients were studied to see whether specific herpes simplex virus antibodies could be differentiated by the immunofluorescence technique. The first group consisted of nine children 1-13 yr old with primary herpetic infections. The second group included two children with generalized neonatal type 2 herpes infection. The third group consisted of ten adults with genital herpes infections. The results were compared with antibody responses seen in rabbits after experimental type 1 or type 2 infection. In both rabbits and children with primary herpetic infections, type 1 and type 2 viral antibodies showed considerable cross-reaction, while in patients with genital herpes infections and in neonates, very little cross-reaction was observed.

- 3172 HL-A ANTIGENS AND CHORIOCARCINOMA. (E.) Rudolph, R. H. (U. Washington Sch. Med., U.S. Public Hlth. Service Hosp., Seattle) and E. D. Thomas. *Lancet* 2(7721):408-409, 1971.

A woman who had given birth to a full-term, live infant and who had developed disseminated choriocarcinoma during that pregnancy was studied with respect to histocompatibility factors using both leukocyte serotyping and one-way mixed-leukocyte culture. Differences in HL-A antigens (leukocyte antigens controlled by genes at the HL-A locus) were found between the infant and his mother with both techniques, disproving the hypothesis that the survival and dissemination of post-gestational choriocarcinoma are dependent upon histocompatibility between the malignant graft and the maternal host. Alternative mechanisms, possibly those involving serum blocking or enhancing factors, which permit tumor-graft survival must be sought.

- 3173 HL-A ANTIGENS IN MALIGNANT BLOOD DISEASES. (Fr.) Jeannet, M. (Canton Hosp., Geneva, Switzerland), P. Alberto and M. Wyss. *Schweiz Med Wchschr* 101(49):1798-1800, 1971.

The frequency of 22 well defined HL-A antigens was determined in 170 patients with malignant blood diseases (34 with acute lymphoblastic leukemia, 33 with acute myeloblastic leukemia, 15 with chronic myeloblastic leukemia, 20 with chronic lymphoid leukemia, 33 with Hodgkin's disease, 21 with other types of lymphomas, and 14 with multiple myeloma); this was compared to the frequency of these antigens

in 350 healthy controls. The most marked anomaly noted was the less frequent occurrence of HL-A 11 among patients with all forms of leukemia and with Hodgkin's disease. Increases were found in the frequency of the following antigens: HL-A in chronic myeloid leukemia, HL-A 2 in acute myeloblastic leukemia, W 15 antigen in Hodgkin's disease, and W 28 antigen in other lymphomas. Although these findings were statistically significant, they should be interpreted with caution since the size of the sample populations tested in each category was relatively small and the degree of significance was not very high and because of serological difficulties. Some anti-HL-A sera gave a larger number of positive reactions with lymphocytes from leukemic patients than with those from the controls, even though the frequency of the corresponding antigens, determined by other sera of similar specificity, was significantly different. These were false positive reactions which were only detected because several sera were used to determine each antigen. The possibility that these sera might contain antigens specific for leukemia is currently being investigated.

- 3174 IMMUNITY AND MALIGNANT MELANOMA OF THE UVEA. (Fr.) Verin, P. (No affiliation), J. Meunier, P. Gendre, J. J. Bergeon, A. Sekkat and S. Morax. *Arch Opht (Paris)* 31(11):781-792, 1971.

The case history of a 56-yr-old man is described; he had a slightly pigmented malignant tumor filling the vitreous body which led to enucleation. Histological examination showed the neoplasm was a fusiform type A Callender sarcoma with very little melanin. Ultrastructural examination disclosed a succession of bright and dark cells associated with necrosis and anomalies of cellular organelles, particularly of centrioles and the Golgi apparatus, and the presence of annulate lamellae. Complete examination of the patient revealed the presence of a suspect hepatic zone which could be latently malignant. Tumor material was grafted beneath the renal capsule of a golden hamster (*Chinchilla* strain), the kidney was repositioned in the abdomen and sutured. On the ninth day the material was removed and examined histologically and ultrastructurally. The originally undifferentiated tissue seemed to have been influenced by an immunological system with signs of differentiation and a reduction in its malignancy. Thus, considerable pigmentation was noted and the annulate lamellae disappeared.

- 3175 REACTION OF ANTI-IDIOTYPIC ANTIBODY WITH THE HAPTEN-BINDING SITE OF A MYELOMA PROTEIN. (E.) Brient, B. W. (U. Illinois Coll. Med., Chicago), J. Haimovich and A. Nisonoff. *Proc Nat Acad Sci USA* 68(12):3136-3139, 1971.

Rabbit antiserum was prepared against mouse myeloma Protein-315, an IgA protein with specificity toward the 2,4-dinitrophenyl group. After absorption of the

antiserum with another IgA myeloma protein and with infinity-labeled Protein-315, the antiserum was specific for idiotype-determinants on Protein-315. Monoclonal ligands that bind to Protein-315 with high affinity strongly inhibited the reaction of the protein with its anti-idiotypic antiserum. This indicated that the region of the hapten-binding site is a major idiotype determinant. The myeloma protein is thus similar to rabbit antibenzoate antibody in this respect. These results, considered in conjunction with other data in the literature, indicate that an anti-idiotypic antiserum prepared in an isologous or heterologous series can recognize the same determinant, in this case the region comprising the ligand-binding site. Quantitative aspects of the data indicate that there is competition between the hapten and anti-idiotypic antibodies for the site.

76 **IN VIVO REQUIREMENT FOR A RADIATION-RESISTANT CELL IN THE IMMUNE RESPONSE TO SHEEP ERYTHROCYTES.** (E.) Gorczynski, R. M. (Ontario Cancer Inst., U. Toronto, Canada), R. G. Miller and A. Phillips. *J Exp Med* 134(5):1201-1221, 1971.

Experiments were carried out to establish whether the radiation-resistant or A cell has a specific function in the initiation of an immune response in mice to sheep erythrocytes (SRBC). Two methods were found for creating an A-cell deficiency *in vivo*: (a) A cells disappear gradually from the spleens of irradiated mice, presumably by migration since A-cell function was shown not to be decreased by irradiation. Three days elapse between irradiation and transplantation of mixtures of bone marrow and thymus cells which provide B and T but few A cells, the usual synergistic response does not occur. Addition of large numbers of freshly irradiated spleen cells to the mixture of bone marrow and thymus completely restores the immune response. (b) Injection of 10^{10} sheep erythrocytes into mice suppresses A-cell activity in these mice 24 hr later; a much reduced response to SRBC is obtained when they are given at a later time. The response can be partially restored if irradiated spleen cells are given with the SRBC. This observation formed the basis for a quantitative *in vivo* assay for A cells in which the magnitude of restoration by various suspensions of irradiated spleen cells was used to estimate the A-cell activity of that suspension. A quantitative *in vitro* assay for A cells was also developed. It was essential for this assay that the total cell number, B-cell number, and T-cell number be kept constant and that only the number of A cells be allowed to vary. Only under these conditions was the response a linear function of the number of A cells added. To determine whether *in vivo* and *in vitro* assays were detecting the same class of radiation-resistant cells, the physical properties of the cells active in each assay were investigated. Spleen cells were separated on the basis of both density and sedimentation velocity. Fractions from both separation methods were tested for their content of A cells using both the *in vivo* and *in vitro* assays. Both density and sedimentation profiles of A cells were similar in both assays. The demonstration that a radiation-resistant cell is required *in vivo* and

that this cell has properties identical to the radiation-resistant cell required *in vitro* indicates that this cell (the A cell) is directly involved in the initiation of an immune response to erythrocyte antigens.

3177 **LEVELS OF C'3 IN THE SERUM OF PATIENTS WITH BENIGN AND MALIGNANT DISEASES OF THE PROSTATE.** (E.) Ablin, R. J. (Southern Illinois U. Sch. Med. Springfield), M. J. Gonder and W. A. Soanes. *Neoplasma* 19(1):61-65, 1972.

The concentration of the C'3 component of the complement (C') system was measured in serum of patients with benign prostatic hypertrophy (BPH) and in patients with carcinoma of the prostate (CaP). The C'3 concentration was measured as β_{1A} -globulin using a single radial immunodiffusion plate method. The normal mean C'3 concentration (measured in serum of normal healthy subjects) was established as 134 ± 30.9 mg/100 ml serum. Ten percent of 30 BPH patients showed elevated C'3 levels (i.e., 195.9 mg/100 ml or more). Seventeen percent of BPH serum samples showed depressed C'3 levels (i.e., 72.3 mg/100 ml or less). Twenty-seven percent of 22 CaP patients showed elevated C'3 levels; no CaP patient had a serum C'3 level of less than 120 mg/100 ml serum.

3178 **AVIAN LEUKOSIS ANTIBODY RESPONSE IN INDIVIDUALS GIVEN CHICKEN EMBRYO DERIVED VACCINES.** (E.) Richman, A. V. (Nat'l. Inst. Hlth., Bethesda, Md.), C. G. Aulisio, W. G. Jahnes and N. M. Tauraso. *Proc Soc Exp Biol Med* 139(1):235-237, 1972.

Sera from individuals inoculated with avian leukosis virus (ALV)-contaminated vaccines were examined for the presence of antibodies to ALV using the broadly reactive COFAL test and the more sensitive indirect immunofluorescence (FAB) test. Neutralization tests were performed on some sera. Samples included sera from subjects given single or multiple doses of ALV-contaminated influenza vaccine, typhus vaccine, measles vaccine, and ALV-free yellow fever vaccine. Virtually 100% of individuals given influenza and typhus vaccines contaminated with ALV developed a significant antibody response. COFAL titers ranged from 1:5 (in a patient given contaminated influenza vaccine) to 1:20 (in a patient given contaminated typhus vaccine). All other sera were negative for COFAL antibody, and all sera tested were negative in neutralization and FAB tests. Because the FAB test is considerably more sensitive than the COFAL test, it was concluded that the COFAL reactions were probably false positives. The data corroborated the lack of immediate infectivity of ALV for man.

3179 **IMMUNOGLOBULIN AND θ -BEARING MURINE LEUKEMIAS AND LYMPHOMAS.** (E.) Shevach, E. M. (Nat'l. Inst. Allergy Infec. Dis., Bethesda, Md.), J.

D. Stobo and I. Green. *J Immun* 108(5):1146-1151, 1972.

Twenty-four murine leukemias and lymphomas and eight plasma cell tumors were examined for the presence of the θ isoantigen or surface immunoglobulin (kappa light chain determinants) by both a chromium release cytotoxicity test and the immunofluorescence test. θ Isoantigen signified that tumors contained thymus-derived T lymphocytes responsible for cell mediated immunity, and the kappa light chain determinants signified that tumors contained bone marrow-derived antibody precursor cells (B cells). Twelve of the 24 tumors bore the θ isoantigen and were presumably of T cell origin. No θ -positive tumor bore surface immunoglobulins as detected by the anti-kappa reagent used. Only one non-plasma cell tumor bearing kappa chain determinants could be identified. Eleven tumors bore neither θ isoantigen nor surface immunoglobulin. Four plasma cell tumors had surface kappa determinants; no plasma cell tumors which had the θ isoantigen had kappa light chain determinants, and vice versa.

3180 IMMUNOGLOBULIN RECEPTORS ON A MOUSE MAST CELL TUMOR. (E.) Cline, M. J. (U. California Sch. Med., San Francisco) and N. L. Warner. *J Immun* 108(2):339-345, 1972.

Mouse mastocytoma cells were incubated with IgG immunoglobulin-coated sheep erythrocytes (SRBC) in a protein-free medium. Rosettes of erythrocytes formed around certain mast cells. When certain immunoglobulins, including mouse IgG₁, IgG_a and IgG_{2b} proteins, were preincubated with mastocytoma cells, rosette formation with IgG-coated SRBC was inhibited. Mouse IgG and IgM, and human myeloma proteins IgG, IgA, and IgM, failed to inhibit rosette formation with IgG-coated SRBC. Pepsin-digested IgG antibody-coated SRBC did not bind to the mast cell. Immunoglobulin in combination with specific antigen bound to mastocytoma cells more strongly than did immunoglobulins alone. Seven cell lines other than the mastocytoma line were tested for rosette formation with IgG-coated SRBC. Only one line, from a mouse plasmacytoma, formed rosettes. Fluorescein isothiocyanate, iodacetamide and phospholipase-C inhibited rosette formation on mastocytoma cells, but phospholipase-D, neuraminidase, and azide did not. Treatment of mast cells with trypsin enhanced rosette formation with IgG-coated SRBC.

3181 CORRELATION BETWEEN SERUM ALPHA-GLOBULIN AND PLASMA INHIBITORY EFFECT ON PHA-STIMULATED LYMPHOCYTES IN COLON CANCER PATIENTS. (E.) Hsu, C. C. S. (Columbia Presbyterian Med. Ctr., New York, N.Y.) and P. LoGerfo. *Proc Soc Exp Biol Med* 139(2):575-578, 1972.

Plasma was taken from 15 normals and from 15 patients with colon cancer; most cancer patients were in the early stages of the disease. Plasma was mixed with PHA-treated lymphocytes from two donors in two groups of experiments and the inhibition of the lymphocyte response to PHA by plasma from normals and colon

cancer patients was observed. On the whole, there was no difference between the inhibition of the lymphocyte response to PHA by normal plasma and that of the lymphocyte response by patients' plasma. Within the group of cancer patients' plasma, however, it was found that plasma from patients with higher levels of serum carcinoembryonic antigen (CEA) produced a higher degree of inhibition of lymphocyte response to PHA. It was noted that serum CEA was higher in patients in advanced stages of colon cancer. A high degree of lymphocyte inhibition was also correlated with high levels of serum α -globulin, and with high levels of both CEA and α -globulin in sera from individual patients. No correlations were found between inhibition of lymphocyte response to PHA and serum levels of other fractions of serum proteins and blood urea nitrogen, uric acid, calcium, phosphorous and liver function tests.

3182 ANTIBODY-MEDIATED SUPPRESSION OF GRAFTED LYMPHOMA CELLS: I. PARTICIPATION OF A HOST FACTOR(S) OTHER THAN COMPLEMENT. (E.) Shin, H. S. (Johns Hopkins U. Sch. Med., Baltimore, Md.), N. Kaliss and D. Borenstein. *Proc Soc Exp Biol Med* 139(2):684-689, 1972.

Inbred mice of four strains were given injections of cells from two murine lymphomas mixed with preparations of two humoral antibodies against these lymphomas. An anti-lymphoma antibody developed in AKR mice (AKR anti-L707) suppressed grafts of a lymphoma indigenous to B10.D2-old mice to the same extent in B10.D2-old and B10.D2-new mice. The AKR anti-L707 lacked complement C5 (for which AKR and B10.D2-old mice are congenitally deficient). This indicated that the presence of complement C5 was not essential for the suppressive efficiency of the antiserum. Whether an intact complement system was needed for tumor suppression was further tested with grafts of lymphoma 6C3HED (indigenous to C3H mice). C3H mice, which have an intact complement system, were treated with cobra venom factor to deplete complement graft recipients; cobra venom factor abolished C3 activity. Despite the absence of C3, the anti-lymphoma antibody B6 anti-6C3HED was fully suppressive of lymphoma grafts. Whole body irradiation (400 R or more) abolished graft recipients' capacity to suppress tumor grafts in the presence of antibody despite the fact that irradiation did not diminish complement activity. Results suggested that complements C3 and C5 were not required for antibody-mediated destruction of lymphoma grafts.

3183 "UNMASKING" OF HUMAN LYMPHOID CELL HETERO-ANTIGENS BY NEURAMINIDASE TREATMENT. (E.) Rosenberg, S. A. (Nat'l. Cancer Inst., Bethesda, Md.), B. A. Plocinik and G. N. Rogentine, Jr. *J Nat Cancer Inst* 48(5):1271-1276, 1972.

Cultured lymphoid cells from a patient with lymphoblastic lymphoma were treated with neuraminidase (NASE) prepared from *Vibrio cholerae*. NASE treatment removed $64.9 \pm 8.3\%$ of the sialic acid from the surfaces of the lymphoid cells. The lysis of

SE-treated cells by treatment with normal rabbit serum (NRS) was assayed by a modification of the ^{51}Cr release cytotoxicity technique. NRS released $26.1 \pm 5\%$ of ^{51}Cr from untreated cells and $50.4 \pm 6.0\%$ ^{51}Cr from NASE-treated cells. NRS was also tested for lysis of lymphoid cells in the presence of carageenan, a complement inhibitor. The lysis of NASE-treated lymphoid cells was eliminated by heat activation and by carageenan. Evidently, NASE treatment "unmasked" surface structure (antigens) on the lymphoid cells, structures which were reactive with other structures (probably antibodies) in NRS. The antibody in NRS could be removed by absorption with SE-treated lymphoid cells in the presence of EDTA without lowering complement. The relative amounts of antigen on the surface of normal and NASE-treated cells were determined by absorbing NRS with cells in the presence of EDTA. NASE-treated cells contained three to four times more antigen than untreated cells.

4 RECEPTORS FOR IMMUNOGLOBULIN AND COMPLEMENT ON MOUSE LEUKEMIAS AND LYMPHOMAS. (E.)

Vach, E. (Nat'l. Cancer Inst., Bethesda, Md.), Herberman, R. Lieberman, M. M. Frank and I. Green. *Immun* 108(2):325-328, 1972.

Twenty-one mouse leukemias and lymphomas, some virus-induced, were examined for the presence of two immunoglobulin and complement receptors. One of the receptors, found on B-lymphocytes, monocytes and macrophages, is an antigen-antibody complement complex receptor identified by binding of red cells coated with antibody and complement (EAC); the other receptor, associated with monocytes and macrophages, is for immunoglobulin G, and is demonstrable by the attachment of red cell-IgG complexes (EA) to the cell surface. Receptors were first screened with a rabbit IgM EAC complex which determined only the lymphocyte or monocyte complement receptor. No tumor bore the lymphocyte receptor. Only three tumors reacted with either IgM or IgG EA complexes. One tumor, induced by anti-light chain and pristane, had both the monocyte EAC complement receptor and the immunoglobulin EA receptor. Two tumors bore the monocyte EA receptor alone. Marked inhibition of binding of the IgG EA complex to both tumor cells and to normal monocytes was produced by the γF (γ_1) and γH (γ_{2b}) subclasses of mouse IgG.

CHANGES OF γ GLOBULIN CARRYING CELLS IN NZB MICE BEFORE AUTOIMMUNE DISEASE. (E.)

Herberman, B. (Manitoba Inst. Cell Biol., Winnipeg, Canada) and F. Paraskevas. *J Immun* 108(5):1465-1466, 1972.

Suspensions were prepared from spleens, thymuses, marrows and cervical lymph nodes of NZB mice. Mice, which have a high incidence of autoimmune diseases, especially among females, were studied before the onset of any such disease (mice were 4-12 weeks of age). Cell suspensions were examined for immunoglobulin-carrying cells by the reverse immune cytoadherence test, in which a 5S hybrid antibody carrying

one anti- γ -globulin site and one anti-ferritin site, is so employed that γ -globulin-carrying cells form rosettes. A dramatic decrease in immunoglobulin-carrying cells was seen in female mice. The mean rosette count for male NZB mice and for females below five weeks of age was 216.21 ± 26.42 SD. The mean rosette count for females 8-10 weeks of age was 130.87 ± 26.42 SD. The total number of rosettes in spleens of male and female NZB mice was lower than that of BALB/J mice. Factor(s) in the serum of female NZB mice were thought to be responsible for the decrease in γ -globulin-carrying cells; the identity of this factor(s) remains unknown.

3186 THE INFLUENCE OF CALCIUM, MAGNESIUM AND CYCLIC ADENOSINE 3',5'-MONOPHOSPHATE ON THE MIXED LYMPHOCYTE REACTION. (E.) Whitney, R. B. (Ontario Cancer Treatment Res. Fdn., London, Canada) and R. M. Sutherland. *J Immun* 108(5):1179-1183, 1972.

Human peripheral lymphocytes from venous blood were cultured and the mixed lymphocyte reaction was monitored by assessing the incorporation of methyl- ^3H -thymidine by lymphocytes. Increasing concentrations of ethylenediamine-tetraacetic acid (EDTA), a strong chelator of divalent cations, progressively inhibited the incorporation of ^3H -thymidine in mixed lymphocyte cultures beginning at a concentration of 1×10^{-4} M or higher. This inhibition was not due to cell death. Probably, the EDTA effect was caused by the removal of divalent cations from the medium (in fact, Ca^{++} and Mg^{++} were required for the initiation and completion of the mixed lymphocyte reaction, and transformation of lymphocytes did not occur in cultures deficient in Ca^{++} or Mg^{++}). Low concentrations (10^{-6} to 10^{-4} M) of exogenous cyclic adenosine 3',5'-monophosphate (cAMP) produced a moderate enhancement of the mixed lymphocyte reaction, but only if cAMP was added just before the isotope incorporation period. If cAMP was added at the start of culture all concentrations except 10^{-6} M produced marked inhibition of the mixed lymphocyte reaction.

3187 IMMUNOLOGIC STUDIES OF NORMAL, BENIGN, AND MALIGNANT HUMAN PROSTATIC TISSUE. (E.) Ablin, R. J. (Southern Illinois U. Sch. Med., Springfield). *Cancer* 29(6):1570-1574, 1972.

The antigenic reaction patterns of saline extracts of normal, benign and malignant human prostate tissue (designated NHPE, BPE and CaPE, resp.) to rabbit antisera were studied in double diffusion gel precipitation tests. Absorption of anti-NHPE sera with lyophilized pooled preparations of BPE or CaPE resulted in the removal of lines of precipitation previously seen between anti-NHPE and BPE, and between anti-NHPE and CaPE. This suggested that BPE and CaPE may have been antigenically deficient in comparison to NHPE. The benign and malignant prostatic tissue may have contained reduced concentrations of normal prostate tissue-specific antigens, or may have lacked these antigens altogether.

- 3188 FUNCTIONAL DEVELOPMENT OF THE INTERACTING CELLS IN THE IMMUNE RESPONSE: I. DEVELOPMENT OF T CELL AND B CELL FUNCTION. (E.) Chiscon, M. O. (Dept. Biol. Sci., Purdue U., Lafayette, Ind.) and E. S. Golub. *J Immun* 108(5):1379-1386, 1972.

In an attempt to determine at what time in development thymus cells become capable of interacting with adult bone marrow cells (i.e., at what time thymus cells acquire T cell function), CBA mice were lethally irradiated and injected with syngeneic adult bone marrow cells. After a delay, animals were given syngeneic thymus cells from fetal and neonatal mice of various ages and challenged with sheep red blood cells (SRBC). A second dose of SRBC was given four days later, and eight days after the first SRBC dose, host organs were assayed for the presence of antibody-forming cells (i.e., for B cell function) and for T cell function. Spleen, lung and liver cells, and well as thymus cells, were tested for T and B cell function. Less than 10% of adult T cell function was seen in thymus of unborn mice; by birth thymus cells showed 12% of adult T cell function. By 48 hr after birth, young thymus cells had achieved adult T cell function levels. No T cell activity was found in fetal or neonatal lung or liver cells. With birth, thymus T cell function appeared to increase exponentially. Neonatally thymectomized mice reconstituted with thymic cells of various ages confirmed these results. B cell function was seen in spleen one day after birth, but T cell function did not appear in spleen until day four after birth. B cell function was present in fetal and neonatal liver by five days before birth; as birth approached, B cell function of liver surpassed that of adult bone marrow. By day six after birth, liver B cell function equalled that of adult bone marrow. Apparently T cell function develops after B cell function, the former being delayed until the development of a structural thymus.

- 3189 THE RELATIONSHIP BETWEEN THYMUS AND ONCOGENESIS: A STUDY OF THE INCIDENCE OF NON THYMIC MALIGNANCY IN MYASTHENIA GRAVIS. (E.) Papatestas, A. E. (Mount Sinai Sch. Med. City U. New York, N.Y.), K. E. Osserman and A. E. Kark. *Brit J Cancer* 24(4):635-645, 1971.

To investigate the role of the thymus and the effects of thymectomy on human oncogenesis, a comparison was made between the incidence of extrathymic neoplasms in 1243 non-thymectomized and thymectomized myasthenia gravis (MG) patients. Patients were placed in four groups according to presence or absence of thymomas, and according to whether or not they had been thymectomized. The breast was the most common site of extrathymic neoplasms. Based on age and sex distribution, the expected number of extrathymic neoplasms in the period prior to onset of MG was 56; in fact, 25 extrathymic neoplasms were seen prior to MG onset. By contrast, the observed number of neoplasms in MG patients after onset of MG but before thymectomy was 64, considerably higher than the expected number (28). The annual incidence of neoplasms increased sharply with the onset of MG and remained high throughout the

course of the disease in non-thymectomized patients. Of 64 extrathymic neoplasms occurring after MG onset but before thymectomy, 39 were in women and 25 were in men; the expected figures were 14 and 14, resp. Following thymectomy, the annual incidence of extrathymic malignancies decreased to expected levels. It is suggested that abnormal clones of immunocompetent small lymphocytes of thymic origin may play a part in the influence of the thymus in oncogenesis.

- 3190 ANTIGEN-BINDING IgA MYELOMA PROTEINS IN MICE: SPECIFICITIES TO ANTIGENS CONTAINING β -D 1-6 LINKED GALACTOSE SIDE CHAINS AND A PROTEIN ANTIGEN IN WHEAT. (E.) Potter, M. (Nat'l. Cancer Inst., Bethesda, Md.), E. B. Mushinski and C. P. J. Glaudemans. *J Immun* 108(2):295-300, 1972.

Three myeloma proteins derived from three plasmacytomas of BALB/c-type mice were tested in precipitin reactions with natural antigens present in the environment of mice in which the plasmacytomas arose. Antigens included materials in food and bedding of the mice: milling wheat extract, arabinogalactan (larchwood), gum ghatti and a hardwood bedding extract. Two of the myeloma proteins, S10 and T191B, precipitated with arabinogalactan, gum ghatti and hardwood bedding extract. It was noted that these antigens had side chains containing either L-arabinose or 1 \rightarrow 6 linked β -D-galactopyranoses. Oligosaccharides of β 1 \rightarrow 6D-galactopyranose were potent inhibitors of the precipitation of S10 and T191B with arabinogalactan; the tetraose was the most effective inhibitor. The third myeloma protein, T521, did not precipitate with arabinogalactan or gum ghatti; T521 precipitated with an antigen in wheat other than that antigen with which S10 and T191B precipitated. The wheat antigen identified by T521, but not those identified by S10 and T191B, lost its antigenicity after pronase. This suggested that the T521 antigen was a protein.

- 3191 STUDY OF THE TUMOR CELL-LYMPHOCYTE INTERACTION IN PATIENTS WITH BREAST CANCER. (E.) Deodhar, S. D. (Cleveland Clin. Fdn., Ohio), G. Crile, Jr. and C. B. Esselstyn, Jr. *Cancer* 29(5):1321-1326, 1972.

Mammary tumors were removed from 17 patients with mammary cancer; tumor cells were cultured with lymphocytes taken from lymph nodes of tumor donors. The tumor cell-lymphocyte interaction was studied; formation of lymphocyte clumps around tumor cells, cytotoxic effect, and blast transformation were used as measures of tumor cell-lymphocyte interaction. In all ten patients who had no involvement of tumor with axillary lymph nodes, there was significant interaction between tumor cells and nodal lymphocytes. Interaction consisted of clumping of lymphocytes around tumor cells; sometimes clumps were in the form of rosettes. Clumping was sometimes accompanied by marked cytotoxicity. In four patients with extensive involvement of lymph nodes by tumor, no lymphocyte clumping was seen around tumor cells, and blast transformation was minimal or absent. In three others,

ly one axillary lymph node was involved: of these patients, two showed tumor cell-lymphocyte interaction and one showed no interaction. In six patients with nodal involvement, and in whom both nodal and peripheral lymphocytes were studied, nodal lymphocytes showed more tumor cell interaction than peripheral lymphocytes.

2 CHANGES IN THE OPSONIN AND CELLULAR INFLUENCES ON PHAGOCYTOSIS DURING THE GROWTH OF TRANSPLANTABLE TUMORS. (E.) Kampschmidt, R. F. Samuel Roberts Noble Fdn., Inc., Ardmore, Oklahoma) L. A. Pulliam. *J Reticuloendothel Soc* 11:1-10, 1972.

cravascular clearance and tissue distribution of sensitized reticuloendothelial (RE) test lipid emulsion were measured at various stages of tumor growth in rats. The phagocytic activity of the reticuloendothelial system (RES) was enhanced in rats bearing several different transplantable tumors. Most of the increase could be attributed to hepatic uptake, while less emulsion than normal was found in the spleens and lungs of tumor-bearing rats. Liver opsonins and liver phagocytic potential were measured by incubating liver slices from normal or tumor-bearing rats in RE test lipid media containing emulsion from either normal or tumor-bearing rats. There was some suggestion of an inverse relationship between the opsonic activity found in the plasma and the tumor-bearing rat and the rate of *in vivo* clearance of the lipid emulsion. The alterations in phagocytic activity of the tumor-bearing rats seemed primarily to changes in liver weight and liver phagocytic potential.

3 MAMMARY TUMOR VIRUS-ASSOCIATED ANTIGENICITY OF L-1210 MURINE LEUKEMIA CELLS. (E.) Kozlowski, P. (Inst. Immun. Exp. Therapy, Polish Acad. Sci., Wrocław), C. Radzikowski, J. Steuden, J. Szukdlarek and K. Krawczynski. *Arch Immunol Ther* 19:789-799, 1971.

of BALB/c mice (which carry the same H-2 antigens as DBA/2 mice) injected with leukemia L-1210 cells showed cytotoxic activity against these cells. Antiserum was not cytotoxic to normal peritoneal cells of DBA/2 mice. The cytotoxic activity of anti-L-1210 serum could be removed only by adsorption of mammary tumor cells from DBA/2 or C3H mice and to be naturally infected with mammary tumor virus (MTV). This and the finding that L-1210 cells were insensitive to the cytotoxic action of antiserum for other virus-associated antigens of murine leukemias suggested that L-1210 cells carry a mammary leukemia antigen. Anti-L-1210 sera were obtained from MTV-negative as well as MTV-positive DBA/2, BALB/c and (DBA/2xBALB/c) mice. The results indicate (that neonatally infected mice could produce humoral antibodies against MTV-associated antigens, in spite of the presumed specific immunological tolerance of such animals.

3194 DETECTION OF TUMOR-ANTIGENS IN METASTASIS-AFFECTED REGIONAL LYMPH NODES IN CANCER PATIENTS. (Rus.) Kosyakov, P. N. (D. I. Ivanovskii Inst. Virol., Moscow, USSR) and R. P. Pavlyuchenkova. *Vop Onkol* 18(3):41-45, 1972.

Metastases in the liver and lymph nodes of cancer patients were studied with the complement-fixation (CF) and indirect immunofluorescence tests, using rabbit sera treated with each of these tissues. Primary tumors were found in the lung, pancreas, stomach, rectum, breast, and prostate. Saline and lipid extracts of native tumors, liver and lymph node metastases from the same subjects, and saline extracts from normal human spleen were used as antigens in the CF tests. Unheated immune sera adsorbed on formalin-treated suspensions of normal spleen and lung tissue and donkey serum from animals immunized with rabbit globulin were used in immunofluorescence tests. In CF tests, sera treated with liver metastases from a lung cancer patient reacted only with antigens from the same type of tumor. Sera treated with liver and lymph node metastases from pancreatic cancer reacted with their own antigens and with antigens from a breast tumor and its metastases. Sera treated with liver metastases from pancreatic cancer reacted with liver and lymph node antigens, but not with the other three types of tumor antigens. Thus, new antigens which differed from spleen antigens but were identical with primary tumor antigens were found in lymph node metastases. Immunofluorescence tests gave the same results and showed that these antigens were located in the cytoplasm and not in the nucleus. These new antigens were detected in lymph node metastases in six of eight cancer patients studied.

3195 DECREASE IN RESISTANCE TO TUMOR INDUCTION RESULTING FROM BCG VACCINATION. (Rus.) Volegov, A. I. (A. I. Gertzen Moscow Res. Inst. Oncol., USSR), *Vop Onkol* 17(12):87-89, 1971.

The possibility of decreasing resistance of animals to carcinogens by BCG vaccination was studied in 85 female Wistar and hybrid rats (about three months old). Methylcholanthrene (MC) in apricot oil (10 mg/1.0 ml) was administered s.c. (2 mg/100 g body weight). Thirty-one days before MC administration, experimental animals were vaccinated i.p. with a live culture of BCG (5 mg/1.0 ml). Allergy tests were made with s.c. injections of 0.04 ml of a 20% dry purified tuberculin ten days before and 64 days after MC administration. Tumor induction was observed for 164 days after MC injection, and then animals were autopsied. The first tumors appeared on the 107th day in 1/12 vaccinated and 1/12 intact hybrid rats, and 2/21 vaccinated Wistar rats. The tumor incidence was higher in vaccinated than in unvaccinated animals on subsequent days. 13/21 vaccinated Wistar rats and 9/12 vaccinated hybrid rats eventually developed tumors, in comparison to 7/19 intact animals. The average manifestation of allergic reactions in all three groups of vaccinated rats was high 24 hours after tuberculin tests, decreasing after 48 hours. The effect of BCG

vaccination on resistance to tumor development was studied in two-yr-old Wistar rats given MC 1 yr after vaccination and 1-yr-old hybrid rats given MC three months after BCG vaccination. The resistance to tumor formation did not decrease in these Wistar rats by 3.5 months after MC injection: 4/14 vaccinated Wistar rats and 3/8 control rats developed tumors. BCG vaccination increased resistance in hybrid rats: none of the 11 experimental rats developed any tumors for 4.5 months, while 4/10 control rats did.

- 3196 DEVELOPMENT OF CYTOTOXIC ACTIVITY IN IMMUNE LYMPHOCYTES AS A RESPONSE TO GRAFTING OF LEUKEMIC CELLS IN MICE. (Fr.) Leclerc, J.-C. (Saint-Louis Hosp., Paris, France), E. Gomard, J. Pavie and J.-P. Levy. *C R Acad Sci [D] (Paris)* 274(8):1233-1235, 1972.

Two-month-old mice of the C57Bl/6 strain were given a single i.p. injection of YC8 leukemia cells, but no tumors developed. Subcutaneous injection of YC8 cells in Balb/c mice produced localized tumors in eight days with inoculum of 3×10^6 cells and in ten days with inoculum of 3×10^5 cells. In the latter case, 20% of the animals subsequently rejected the tumor. Spleen cells from immunized and control mice were incubated with YC8 cells labeled with Cr-51, and the radioactivity released in the extracellular medium by the YC8 cells was measured. Three days after inoculation spleen cells developed a cytotoxic effect in C57Bl/6 mice grafted with YC8 cells; this effect reached its peak in 7-8 days, then fell off rapidly. A parallelism was noted between the increase in cytotoxic activity and tumor development. When the tumor was rejected, cytotoxic activity kept increasing, even following rejection, then decreased progressively. These results indicate that lymphoid cells capable of destroying tumoral cells *in vitro* form in response to an isogenic graft. Their development differs from that of lymphocytes following immunization of an allogenic recipient.

- 3197 ABSENCE OF PRIMARY IMMUNE RESPONSE IN ACUTE BOVINE LYMPHOCYTIC LEUKEMIA: I. OCCURRENCE OF NATURAL ANTIBODIES AGAINST *E. COLI*. (E.) Celer, V. (Slovak Acad. Sci., Bratislava, Czechoslovakia), L. Cerny, E. Jelinkova and P. Nedbal. *Neoplasma* 18(5):523-528, 1971.

The immune response of a cow with acute bovine lymphosarcomatosis was studied. Although the cow had up to 800,000 lymphoid cells per ml of peripheral blood (6,000 is normal), no antibody producing cells were detected by a plaque-forming technique on the sixth day following intramammary instillation of 10^{12} sheep erythrocytes. A normal immune response was seen in healthy controls. Natural antibodies to a nonhemolytic strain of *E. coli*, serologic type 0-112, isolated from the digestive tract of an experimental cow were detected in the serum of the cow with lymphosarcomatosis. Colorimetric measurement of protein content in gammaglobulins in serum

fractionated on DEAE-Sephadex showed no significant differences between the diseased and a healthy cow. No differences were observed in immunoelectrophoretic patterns either.

- 3198 THE PRIMARY IMPLANTATION OF HUMAN TUMORS TO THE HAMSTER CHEEK POUCH. (E.) Williams, D. E. (Welsh Natl. Sch. Med., Cardiff, Wales), D. M. D. Evans and R. W. Blamey. *Brit J Cancer* 25(3):533-537, 1971.

The growth of 72 human tumors (including 22 breast tumors, 11 uterine cancers, and 15 gastrointestinal adenocarcinomas) was evaluated ten and 20 wk after primary implantation into the cheek pouches of eight-to-12-wk-old Golden hamsters. Half of the animals implanted with each tumor received s.c. injections of cortisone acetate (2.0 mg) at the time of implantation and thereafter twice weekly. Tumors were considered to be "growing" if mitotic figures were present in easily recognizable tumor tissue. Implants were considered "surviving" when recognizable tumor tissue was present in cheek pouches. Twenty-seven of 72 tumors (37.5%) grew in at least one implant. The uterine (nine of 11) and gastrointestinal (six of 15) tumors grew with greatest frequency. The number of implants growing in cortisone-treated animals (123 of 316 implants) was significantly greater ($P < 0.001$) than those growing in untreated controls (49 of 296). Similar results were obtained when methylcholanthrene-induced rat sarcomas were implanted into cheek pouches of cortisone-treated and untreated animals. Squamous carcinomas of the uterine cervix (45 of 82 implants) showed the best percentage of "takes" in cheek pouches of cortisone-treated animals, followed by adenocarcinomas of the corpus uteri (14 of 48) and adenocarcinomas of the colon and rectum (28 of 106). Only seven of 272 implants of breast carcinomas showed growth. It was suggested that such a method of implantation of human tumors into hamster cheek pouches could provide a means of simultaneously studying the effect of antineoplastic agents on tumors and host vital systems, while preserving the whole architecture of the tumors.

- 3199 IMMUNOTHERAPY OF CANCER: IMMUNOSPECIFIC REJECTION OF TUMORS IN RECIPIENTS OF NEURAMINIDASE-TREATED TUMOR CELLS PLUS BCG. (E.) Simmons, R. L. (Dept. Surg., U. Minnesota, Minneapolis) and A. Rios. *Science* 174(4009):591-593, 1971.

Living cells of a 3-methylcholanthrene-induced fibrosarcoma were mixed with 25 U *Vibrio cholerae* neuraminidase (VCN)/ml/ 10^6 cells and mitomycin C; the treated tumor cells were injected into C3H/H3J female mice bearing firmly established methylcholanthrene-induced tumors of the same type as those from which VCN-treated cells were taken. In some cases, Bacillus Calmette-Guerin (BCG) was added to the tumor cell-VCN-mitomycin C mixture. BCG alone, or tumor cells exposed to heat-inactivated VCN plus mitomycin C, or any combination of these treatments,

ed to produce total regression of established tumors in treated mice. However, a single injection of tumor cells exposed to VCN plus mitomycin C produced regression in two of seven tumors. When treated cells were injected in combination with 16 of 56 tumors regressed. The rejection of methylcholanthrene-induced tumor was immunospecific and could be induced only with VCN-treated cells identical in type with the established tumor.

DEMONSTRATION OF ANTIBODIES TO T-ANTIGENS OF VARIOUS ORIGINS IN SERA OF MONKEYS WITH SARCOMA AND OF MONKEYS INFECTED WITH ADENOVIRUS TYPE 12. (Rus.) Adzhigitov, F. I. (Inst. Path. Therapy, USSR Acad. Med. Sci., Sukhumi), Degtyarenko, N. I. Zatsepin, A. V. Pertaya and Gubeladze. *Doklady Akademii Nauk SSSR* 202(6):1434, 1972.

Sera of nine adult rhesus monkeys with induced sarcomas and the sera of nine rhesus monkeys infected repeatedly with human adenovirus type 12 (from birth to four yr of age) were assayed for antibodies. Tumors were induced in hamsters by virus, human adenovirus type 12, or SV-40 and as antigens together with normal hamster liver. The antigens were freeze dried after ultrasonic treatment and centrifugation. Control tests were done on sera of five healthy rhesus monkeys. Sera from infected and control monkeys were tested with cold micro-complement fixation method from infected and control monkeys. Antibodies to T-antigen of hamster Rous sarcoma were found in sera of all monkeys with Rous sarcoma. This indicates the presence in them of group-specific antigens of the leukemic-sarcoma complex found in chickens. Sera from monkeys infected with adenovirus type 12 reacted positively with T-antigen of hamster Rous sarcoma. High antibody titers to T-antigen of hamster Rous tumors induced by virus SV-40 were found in sera from monkeys with Rous sarcoma. Antibodies to normal liver antigens were found in the sera of both groups of monkeys less frequently. Antibodies to T-antigens in titers not exceeding 1:8. In control sera, reactions were negative with all the antigens studied. The findings indicate that antibodies to antigens commonly found in hamster tumors induced by RNA- or DNA-tumor viruses can be produced in rhesus monkeys infected with Rous virus and adenovirus type 12.

MIGRATION OF TUMORAL CELLS: SPECIFIC INHIBITION BY SENSITIZED LYMPHOID CELLS.

Le Mevel, B. (Paul Brousse Hosp., Inst. Experimental Immunogenetics, Villejuif, France), M. J. Giannakis and J.-F. Dore. *C R Acad Sci [D] (Paris)* 275(5):758-760, 1972.

Effect of adding specifically sensitized lymphoid cells to culture medium on the *in vitro* migration of leukemia cells from capillaries was studied. Leukemia was induced in adult C57Bl/6 mice

with Gross virus, and ascites was transplanted to isogenic recipients. Spleen cells from these C57Bl/6 mice who had been injected seven days earlier with 10^7 leukemia cells were added in different quantities to the culture medium and the migration of tumor cells was compared with that in media to which the same number of spleen cells from normal C57Bl/6 and C3H/He mice had been added. While the addition of allogenic spleen cells did not inhibit the migration of leukemia cells appreciably, addition of spleen cells from leukemic mice had a pronounced migration-inhibiting effect, even in media containing the smallest number of leukemia cells. The specificity of this effect was established by comparing cell migration in the presence of isogenic and allogenic normal mouse cells with cell migration in the presence of allogenic immunized cells (from C3H/He mice immunized three times with a s.c. injection of AkR(K36) cells). Normal allogenic spleen cells had a less pronounced migration-inhibiting effect than specifically immunized allogenic spleen cells. Thus, *in vitro* migration of leukemia cells can be inhibited by lymphoid cells from tumor-bearing mice. However, the nature of the lymphoid cells responsible for this phenomenon and their action mechanism remain unknown.

3202 IMMUNOLOGICAL STUDY COMPARING MITOCHONDRIA, ISOLATED FROM C3H MOUSE MAMMARY GLAND CARCINOMA AND FROM HOMOLOGOUS NORMAL TISSUE. (Fr.) Bourlioux, P. (Rene-Descartes U., Virol. Immunol. Lab., Paris, France) and A. German. *C R Acad Sci [D] (Paris)* 274(9):1438-1441, 1972.

A comparative immunological study of the antigenic properties of mitochondria from mammary tumors of the C3H strain of mice and of mitochondria from corresponding healthy tissues used four types of antigens to immunize rabbits (mitochondria isolated from the tumor, a mitochondrial protein fraction soluble in sodium desoxycholate, a mitochondrial fraction insoluble in sodium desoxycholate, and a mitochondrial protein fraction soluble in dodecyl sulfate). Rabbits were infected i.m. with 1 ml mitochondria or an antigen extract plus 1 ml of complete Freund adjuvant for seven consecutive weeks, followed by two intravenous injections of mitochondria in a sucrose buffer. The reactions induced by the four immunizations were evaluated by Ouchterlony's double-diffusion method on agar by using against these immune sera mitochondrial protein fractions from the tumor extracted by desoxycholate, Triton, Duponol, and dodecyl sulfate, and by using mitochondrial protein fractions from healthy tissue extracted in the same way. Mitochondria from tumor tissue contained an antigen which is absent in healthy tissue. These findings confirm those found previously in an electrophoretic study.

3203 AUTOANTIBODIES TO HUMAN RENAL CELL CARCINOMA. (E.) Ravitz, G. (West Virginia U. Sch. Med., Morgantown), A. L. Watne and D. F. Milam. *J Urology* 107(1):26-28, 1972.

Humoral (globulin) antibodies have been demonstrated against the cells of hypernephroma using immunofluorescent techniques. No common antigen was demonstrable by cross-reaction. One patient with metastatic disease had no antibodies demonstrated. In another patient with a weak reaction metastases soon developed. One patient demonstrated antibody against his own normal kidney. No cross-reaction to pooled normal sera was demonstrated. No cross-reaction with fetal kidney was demonstrated.

- 3204 SUPPRESSIVE EFFECT OF IMMUNIZATION WITH MOUSE FETAL ANTIGENS ON GROWTH OF CELLS INFECTED WITH RAUSCHER LEUKEMIA VIRUS AND ON PLASMA-CELL TUMORS. (E.) Hanna, M. G., Jr. (Oak Ridge Natl. Lab., Tenn.), R. W. Tennant and J. H. Coggin, Jr. *Proc Nat Acad Sci USA* 68(8):1748-1752, 1971.

Male BALB/c mice were injected once a wk for three wk with X-irradiated viable embryo cells from BALB/c mice. Embryo cell-primed mice were irradiated and implanted with Millipore diffusion chambers containing Rauscher leukemia virus (RLV)-infected BALB/c spleen cells. Other embryo cell-primed mice were injected with RLV to induce splenomegaly, or given transplants of an ascites plasma-cell tumor. Recovery of RLV-infected spleen cells in implanted diffusion chambers was depressed to 60 or 49% of normal in mice primed with embryo cells. Splenomegaly induced by RLV and cumulative mortality from a transplanted ascites plasma cell tumor were also suppressed in embryo cell-primed mice. RLV-induced splenomegaly was also suppressed by adoptive transfer of BALB/c spleen cells from newborn mice to BALB/c mice. Injections of neonatal BALB/c cells did not suppress recovery of RLV-infected spleen cells, splenomegaly, or mortality of tumor transplant recipients among BALB/c mice not primed with embryo cells. Priming of mice with embryo cells did not suppress primary immunoglobulin M response to heterologous erythrocyte antigen in normal BALB/c spleen cells. Apparently, BALB/c embryos possessed components, presumably antigens, common to RLV-infected spleen cells and a plasma-cell ascites tumor. Also, the plasma-cell tumor appears to be among those human and animal tumors which contain neoantigens that cross-react with antigens of fetal cells.

- 3205 THE USE OF THE PROTEOLYTIC ENZYME BRINASE TO PRODUCE AUTOCYTOTOXICITY IN PATIENTS WITH ACUTE LEUKEMIA AND ITS POSSIBLE ROLE IN IMMUNOTHERAPY. (E.) Thornes, R. D. (Royal Coll. Surg. Ireland, Dublin), P. F. Deasy, R. Carroll, D. J. Reen and J. D. MacDonell. *Cancer Res* 32(2):280-284, 1972.

The ability of the proteolytic enzyme, brinase, to reproduce complement-dependent autocytotoxicity against leukemia cells, lymphocytes and possibly platelets was studied. Daily infusions of brinase, a proteolytic enzyme isolated from *Aspergillus oryzae*, were given for 10 to 30 days to six acute leukemia patients. Dosage given was 2.5 mg/kg of body weight in children and 100 to 300 mg daily to adults. Autocytotoxicity was assayed

on serum samples from patients by incubating the serum for 2 hr at 37 C in 0.001 ml quantities with 1,000 lymphocytes and 0.005 ml of complement. Testing was considered positive when more than 20% of the cells were killed. Results indicated that the autocytotoxicity initiated by brinase was temporary, lasting from three to 15 days, but repeat courses of brinase, alone or in combination with anti-leukemic drugs, produced further autocytotoxic "antibodies". Remission was obtained in three of five patients given combination therapy and in one patient with acute myeloblastic leukemia who was treated by brinase alone.

- 3206 INCREASED INCIDENCE OF LYMPHOMAS IN THYMECTOMIZED MICE--EVIDENCE FOR AN IMMUNOLOGICAL THEORY OF AGING. (E.) Cornelius, E. A. (Yale U. Sch. Med., New Haven, Conn.). *Experientia* 15(4):459, 1972.

(C57B1/1XA) F₁ hybrid mice were thymectomized after birth and observed twice weekly for the presence of lymphoreticular tumors. Similar F₁ hybrids, not thymectomized, served as controls. Although tumors first appeared in both groups after five months, the incidence of tumor at a given age was significantly higher in the thymectomized group than in the controls for all ages (up to 24 months) observed. Up until the seventh month the rate of increase in tumor incidence was much higher for the experimental group than for the controls. Beginning at about the 17th month, the slope of the control curve plotting the rate of tumor incidence became greater than that of the experimental curve so that ultimate convergence of the two curves was evident. Since the thymus-dependent system is primarily concerned with immunological surveillance, these results were considered as supporting evidence for the gradual exhaustion of this immunological system with aging. Such exhaustion would manifest itself by an increased incidence of tumors in deficient mice.

- 3207 HUMAN CARCINOMA ANTIGENS CROSS REACTING WITH ANTI-EMBRYONIC ANTIBODIES. (E.) Klavins, J. V. (Queens Hosp. Ctr., New York), R. Mesa-Tejada and M. Weiss. *Nature New Biol* 234(48):153-154, 1971.

A 6-7 wk old intact human fetus from a patient with ectopic pregnancy, was homogenized and then centrifuged. The supernatant was dialysed and lyophilized. A New Zealand white male rabbit was immunized and three injections of the lyophilized fetal extract resuspended in bacteriostatic water and emulsified with complete Freund's adjuvant were administered s.c. at weekly intervals and a booster injection was given intramuscularly one wk after the last injection. Thereafter, injections were given intramuscularly at monthly intervals and blood was collected from the marginal ear vein ten days after each booster. The Ouchterlony double diffusion technique was used to demonstrate that the rabbit serum contained antibodies reacting with the extracts of two

inomas of colon, a carcinoma of breast, a sarcoma, a squamous cell carcinoma, a clear cell carcinoma of kidney, a bronchogenic carcinoma and a carcinoma of skin. These antibodies did not react with extracts of adult spleen, kidney, lung, liver, heart and intestine. Indirect immunofluorescence microscopy showed that the absorbed rabbit antiserum, after incubation with various kinds of tissues, was bound to the cells of the six types of carcinomas and to the epidermis of the adult skin. It did not bind to the normal adult tissues. These findings indicate that in man, carcinomas corresponding to the three germinal layers contain antigens which react with the antibodies against the components of embryonic tissues.

HERPES ZOSTER-VARICELLA INFECTIONS AND LYMPHOMA. (E.) Goffinet, D. R. (Stanford U. Sch., Calif.), E. J. Glatstein and T. C. Merigan. *Ann Intern Med* 76:235-240, 1972.

Review of 1130 patients with lymphoma, examined at the Stanford Medical Center over a ten-year period (1959 to 1969), shows 129 (11.4%) patients with one or more episodes of typical herpes zoster-varicella infection. Five hundred and ninety-two patients had Hodgkin's disease, and in this group 91 cases of herpes zoster-varicella infection (15.4%) were detected. Five hundred and thirty-eight patients with lymphoma other than Hodgkin's disease; of these, 24 developed herpes zoster-varicella (7.1%). All patients were analyzed according to age, clinical status, site of lymphoma when infection occurred, and survival after either localized or disseminated disease. The effects of antitumor chemotherapy including combination chemotherapy, are presented. A significantly increased incidence of herpes zoster-varicella infections was found in the 150 patients with Hodgkin's disease who underwent splenectomy either as part of their initial evaluation and staging or during the course of their disease, although survival of this group was apparently unchanged by the infectious complication of their lymphoma.

INDUCTION OF TUMORS IN NEONATALLY THYMECTOMIZED MICE. (E.) Cornelius, E. A. (Yale Sch. Med., New Haven, Conn.). *Transplantation* 19:531-532, 1971.

The incidence of spontaneously occurring tumors in neonatally thymectomized and normal mice of the C57BL/1 strain and age was compared. (C57BL/1 x A)F₁ hybrid mice were subjected to thymectomy 24 hr after birth; sham operated mice of the same strain constituted the control group. Each animal in both groups was examined twice weekly; any tumors detected were confirmed by autopsy. Tumors were detected during the fifth month in both thymectomized and control mice, and the difference in incidence was not significant. At the end of the sixth month a significant difference became

apparent, with four of the test animals having developed tumors versus only one of the control group. At this point the number of tumors increased rapidly in the thymectomized mice while the control mice continued to exhibit a very low incidence of tumor growth. By 22 months, 31 out of 77 mice had developed tumors among the test animals and only 12 out of 149 control animals were tumor-bearing. The tumors were shown histologically to be lymphoreticular. Two possible etiological mechanisms for the greatly increased incidence of lymphoreticular tumors in aged, neonatally thymectomized mice are: 1) immunological deficiency, allowing mutant malignant clones of cells to proliferate; and, 2) autoimmunity, and subsequent hyperplastic change caused by bacterial or viral agents.

3210 IMPAIRED LYMPHOCYTE TRANSFORMATION IN LEUKEMIC PATIENTS AFTER INTENSIVE THERAPY. (E.) Humphrey, G. B. (U. Oklahoma Med. Ctr., Oklahoma City), M. E. Nesbit, Jr., K. K. N. Chary and W. Krivit. *Cancer* 29(2):402-406, 1972.

Lymphocyte transformation was measured to assess immunologic competence in acute lymphatic leukemia. The *in vitro* lymphocyte transformation in response to pokeweed mitogen was studied in three groups of children: 1. 11 normal controls, 2. nine leukemic children in remission who had not received intensive therapy, and 3. nine leukemic children who had completed intensive x-ray and chemotherapy. The responses of the first and second groups were similar. In the third group, lymphocyte transformation was impaired one month after all therapy had been discontinued in 8/9 patients. Six of these nine patients were studied two months after cessation of therapy and the lymphocyte transformation was still impaired (6/6). Serial monthly studies in three patients demonstrated that this impaired transformation persisted for three months or longer. Intensive forms of chemotherapy-radiotherapy used to treat acute lymphatic leukemia can cause prolonged impairment of lymphocyte transformation.

3211 DEMONSTRATION AND PURIFICATION OF A SPECIFIC ANTIGEN IN MORRIS HEPATOMA 5123. (E.) Kyriazis, A. P. (Dept. Path., U. Chicago, Ill.) and R. W. Wissler. *Lab Invest* 26(2):178-183, 1972.

A specific antigen related to the Morris line 5123 minimal deviation hepatoma has been characterized and highly purified. The Morris 5123 hepatomas, which were grown in Buffalo strain adult male rats, were removed, and homogenized; the cell membranes were isolated and digested with papain. Preparatory fractionation on a CM-Sephadex C-25 column revealed four fractions; the first one contained the specific precipitin line developed with the absorbed antiserum and was fractionated further on

Sephadex G-200. When the two fractions resulting from this purification step were studied by analytical disc electrophoresis and immunodiffusion the more slowly moving protein component of fraction I, with an R_f of 0.27 to 0.28, was found to react with the completely absorbed antiserum. The homogeneity of this specific component was demonstrated by polyacrylamide gel electrophoresis. The techniques used in this study may prove useful for solubilizing and isolating tumor-specific antigens in human tumors and for developing immunogens for cancer therapy.

- 3212 ADJUVANT EFFECT OF ENDOTOXIN ON PRIMARY ANTIBODY FORMATION IN IRRADIATED RATS. (E.) Elekes, E. (Natl. Res. Inst. Radiobiol. Radiohyg., Budapest, Hungary), K. Meréty and V. Várterész. *Path Microbiol* 37:302-312, 1971.

Male Wistar rats were irradiated (750 R) to abolish the primary immune response and to hold antibody-forming capacity at a low level for a period of 45 days. The rats were then given sheep red blood cells (SRBC) i.v., either with or without *E. coli* endotoxin, over a period of one month. During the first week after irradiation, endotoxin treatment induced a mild decrease in plaque-forming cells, but after the 10th day, it resulted in a comparatively earlier regeneration of the antibody-forming capacity. By the end of the first month the antibody response to SRBC returned to normal levels in the endotoxin-plus-SRBC-treated group, while irradiated animals remained impaired. Formation of anti-SRBC plaque-forming cells was similar. Endotoxin-induced splenomegaly was seen in all groups to which endotoxin was administered. In addition, increases in serum hemolysin titers could be found earlier and at higher levels in endotoxin-treated irradiated animals than in nonirradiated rats immunized solely with SRBC. These experiments suggest that the endotoxin-induced effects may present a significant contribution to the regeneration of the immune response.

- 3213 FURTHER OBSERVATIONS ON WHETHER HOST IMMUNODEPRESSION IS ASSOCIATED WITH TUMOUR GROWTH IN MICE. (E.) Rees, J. A. (U. Bristol Med. Sch., England) and M. O. Symes. *Brit J Cancer* 25(3):501-504, 1971.

To investigate whether the presence of a tumor was associated with immunodepression in the host, spleen cells from parent A-strain mice bearing A-strain mammary carcinoma transplants were injected i.v. into (AxCBA) F_1 hybrids, half of which carried the same tumor. Other F_1 hybrids, with and without tumors, received spleen cells from non-tumor-bearing parent-line animals. The ability of parent-line spleen cells to induce a graft versus host (GVH) reaction in the four groups of F_1 hybrids was assessed by comparing the mean spleen indices (ratio of the spleen weight of the F_1 hybrid receiving the injection to that of the

control). No differences in GVH responses were observed and it was concluded that parent line cells from tumor-bearing or from non-tumor-bearing donors were equally effective in inducing a GVH reaction, whether or not the F_1 hybrid recipient carried a tumor. Similar results were obtained from parent lines bearing a different mammary carcinoma and lines bearing a 3-methylcholanthrene-induced sarcoma.

- 3214 IN VITRO STUDY OF CELLULAR IMMUNITY AGAINST AUTOCHTHONOUS HUMAN CANCER. (E.) Segall, A. (Inst. Gustave-Roussy, Villejuif, France), O. Weiler, J. Genin, J. Lacour and F. Lacour. *Int J Cancer* 9(2):417-425, 1972.

A study of cell-mediated immunity has been undertaken *in vitro* by the leukocyte migration test (LMT) on 57 patients with operable carcinoma. Tumor extracts induced an inhibition of autologous leukocyte migration in 58% of the cases: 10 out of 17 lymphomas, 10 out of 15 malignant mesenchymal tumors, 8 out of 13 mammary carcinomas, 2 out of 4 melanomas, and 3 out of 8 various other tumors. Migration of mononuclear cells was especially inhibited but not that of neutrophils. Thus a previous sensitization of the lymphocytes by tumor antigen(s) has been shown. On the contrary, 9 extracts of benign and 17 extracts of normal tissue did not significantly inhibit the migration of autologous cells. Almost all tumor extracts were tested against allogeneic leukocytes from patients bearing the same or a histologically different type of tumor, or from healthy subjects (101 cases). Cross-reactions were observed in five melanomas, in one case of Hodgkin's disease, and in one breast carcinoma. In all but two cases, inhibition of leukocyte migration did not occur in patients with a different type of tumor or in non-cancerous patients.

- 3215 THE PRODUCTION OF COMPLETE AND INCOMPLETE ANTIBODIES IN PATIENTS WITH NEOPLASTIC DISEASE. (E.) Wagner, V. (Inst. Care Mother Child, Prague, Czechoslovakia), O. Janku, M. Wagnerova, J. Mates and Z. Konickova. *Neoplasma* 19:(1):75-87, 1972.

Antibody formation (complete and incomplete) after single s.c. injection of heat-killed *Brucella* was examined in patients with malignant diseases. Blood specimens were collected 1, 2 and 3 wk after immunization. The results were correlated with clinical data and compared with two control groups. In the 1st and 2nd wk the patients with malignancies showed a decreased complete antibody formation and lower titers of incomplete antibodies. No significant differences were found in antibody response related to the stage of malignant tumor, or the length of survival of the patient. The defect of antibody formation in patients with malignancies is discussed. It is proposed that lower antibody formation in patients with malignant tumors is not a consequence of malignant tumor, but seems to be a property of every malignant disease.

- 3230 DISTINCTION BETWEEN THE PRENEOPLASTIC AND NEOPLASTIC STATE OF MURINE MAMMARY GLANDS. (E.) Hazlewood, C. F. (Baylor Coll. Med., Houston, Tex.), D. C. Chang, D. Medina, G. Cleveland and B. L. Nichols. *Proc Nat Acad Sci USA* 69(6):1478-1480, 1972.

Nuclear magnetic resonance spectroscopy was used to measure the relaxation times (T_1 and T_2) and diffusion coefficient (D) of water protons in primary mammary adenocarcinomas arising from nodule outgrowth lines D₁ and D₂ in Balb/c mice and from a nodule outgrowth line in C3Hf mice. The relaxation times and diffusion coefficients of water protons in the carcinomas were almost doubled relative to those of mammary gland tissue from normal pregnant mice and nodule tissue. The relaxation times and diffusion coefficients for the nodule (preneoplastic) tissues were slightly longer than those from mammary gland of normal pregnant females. The possibility that the increased diffusion coefficient of tumor tissue was due to a decreased cell lipid content relative to normal mammary and pre-neoplastic tissues was excluded by the fact the exchange of lipid protons and water protons was found to be negligible.

- 3231 THE PATHOLOGY OF SO-CALLED MEDITERRANEAN ABDOMINAL LYMPHOMA WITH MALABSORPTION. (E.) Rappaport, H. (Chaim Sheba Med. Ctr., Tel-Hashomer, Israel), B. Ramot, N. Hulan and J. K. Park. *Cancer* 29(6):1502-1511, 1972.

Surgical specimens and/or postmortem materials from 22 patients with the syndrome designated as "Mediterranean abdominal lymphoma with malabsorption" were studied in detail. Eighteen of the patients were followed at Tel-Hashomer Hospital, Israel, and four at other institutions. All patients exhibited a malabsorption syndrome. In most of those followed from the onset of the disease, the syndrome seemed to have preceded the development of palpable abdominal masses. The characteristic gross finding in all cases was a diffuse thickening of the mucosa of the small intestine with loss of the intestinal circular mucosal folds. In histological specimens obtained from all 20 patients so studied, diffuse severe plasma cell infiltrations were evident in the intestinal mucosa and submucosa. Malignant lymphomas in the form of single or multiple circumscribed intestinal tumors occurred in 14 of these 20 patients, and malignant lymphomas of the mesenteric lymph nodes in two. In four patients, no malignant lymphomas were evident. These observations suggest that the diffuse plasma cell infiltrations, rather than the malignant lymphomas, were responsible for the malabsorption syndrome. There was no morphological evidence that the malignant lymphomas observed in 16 of 20 patients were histologically related to the diffuse plasma cell infiltration. The possibility is suggested that this abnormal, though probably not neoplastic, proliferation of plasma cells is a morphological manifestation of an immune deficiency state which predisposes the patients to the development of malignant lymphoreticular neoplasms.

- 3232 PRE-LEUKAEMIA IN CHILDREN WITH A MISSING BONE MARROW C CHROMOSOME AND A MYELOPROLIFERATIVE DISORDER. (E.) Humbert, J. R. (U. Colorado Med. Ctr., Denver), W. E. Hathaway, A. Robinson, D. C. Peakman and J. H. Githens. *Brit J Haemat* 21(6):705-716, 1971.

A child is reported who progressively 'lost' a C-chromosome in bone marrow metaphases in a proportion increasing from 9% to 100% over a three yr period. Hematologically the patient had hepatosplenomegaly with myeloid metaplasia, refractory anaemia, leucocytosis and thrombocytopenia. Immature granulocytes and erythrocytes and monocytosis were present in peripheral blood. The patient also had increased fetal hemoglobin and leucocyte alkaline phosphatase. Her blood lymphocyte and skin fibroblast chromosomes were essentially normal. Recent progression of the patient's disorder and study of information available from the literature suggest that this myeloproliferative disorder may represent a preleukemic state.

- 3233 MURAMIDASE IN MYELOPROLIFERATIVE DISORDERS TERMINATING IN ACUTE LEUKEMIA. (E.)

Skarin, A. T. (Harvard Med. Sch., Boston, Mass.), Y. Matsuo and W. C. Moloney. *Cancer* 29(5):1336-1342, 1972.

Studies on serum muramidase (lysozyme) activity (SMA) were carried out on 168 patients with leukemia and a variety of myeloproliferative disorders. Among the cases were three with chronic myelogenous leukemia, one with polycythemia vera, and four with myeloid metaplasia; in these eight cases, transition to acute myeloblastic or acute myelomonocytic leukemia took place. Studies on these eight patients are presented with detailed serial observations in three cases terminating in acute myelomonocytic leukemia. Acute leukemic transition in the latter three cases was associated with striking elevation of SMA and marked muramiduria. In the eight patients in which myeloproliferative disorders progressed to leukemia, leukemia had its onset between two months and five yrs after the onset of the myeloproliferative disorder. The three patients studied in detail showed significant hypokalemia, possibly related to toxic effects of an excess of muramidase on renal tubules.

- 3234 GROWTH *IN VITRO* AND INDUCTION OF DIFFERENTIATION IN CELLS OF BASAL CELL CANCER.

Flaxman, B. A. (Temple U. Hlth. Sci. Ctr., Philadelphia, Pa.). *Cancer Res* 32(3):462-469, 1972.

Human basal cell carcinomas were excised and the epidermis and superficial portions of tumors were dissected away; tumor nodules were established in culture and observed under light- and electron-microscopes. Prior to culturing, tumor nodules showed no keratinization. Three to four days after the start of cultures, epithelial outgrowths appeared around each nodule. Outgrowths formed monolayers at the peri-

eries of nodules, while the central regions were multi-layered and consisted of stratified squamous epithelium. Cell division and DNA synthesis occurred outgrowths wherever outgrowths were multilayered. 30 days, opaque areas had formed in the nodule cultures; significant keratinization was found to have commenced in opaque areas as they formed. Peripherally located cells tended to break away from the outgrowths. Peripheral cells also showed contact inhibition of overlap among themselves, and when confronting normal human epidermal cells. Young nodule cultures consisted primarily of immature undifferentiated cells like those of nodules *in vivo*; older cultures showed differentiation in the form of keratinization. Older cultures also had diminished growth rates.

35 THE DUBREUILH MELANOSIS: A PRECANCEROUS STATE OF MUCOUS MEMBRANES. HISTOLOGICAL AND ULTRASTRUCTURAL ASPECTS. (Fr.) Bonneau, H. (Anticancer Ctr., Marseille, France) and J. P. Cesari. *Bull Cancer (Paris)* 58(2):307-314, 1971.

The histological picture of Dubreuilh's melanosis is characterized by a proliferation of melanocytes which over the basal membrane of the epidermis almost completely; in some specimens very few keratinized cells are present. The histological picture suggests this precancerous melanosis is a true cancer *in situ*. The ultrastructural picture always reveals the presence of keratinized cells, but these are sometimes smaller than 1 μ and thus difficult to see in a light microscope. The melanophores are disorganized with frequently missing peripheral membranes. In Dubreuilh's melanosis of buccal origin a certain number of melanophores have no central opacification, are elongated or rectangular, and are uneven in size. When the keratinized cells disappear, leaving the melanocytes in direct contact with the basal membrane, melanophore anomalies become more frequent and autophagosomes containing melanophores appear. Occasionally, the melanocytes passed through the basal membrane, producing a malignant melanoma. Melanophores in Dubreuilh's melanosis definitely show some characteristics of cancer cells, but to a lesser extent and much less frequently than true cancerous melanophores.

36 HORMONE DISTURBANCES IN WOMEN WITH PRECANCEROUS DISEASES AND CANCER OF THE BREAST. (S.) Kuzmin, V. I. (Republican Oncology Dispensary Chuvash Autonomous SSR, Public Hlth. Ministry, USSR). *Akush Ginekol* 47(9):39-42, 1971.

A total of 640 women with diseases of the breast including 270 with mammary gland cancer, 207 with mastopathy, and 163 with fibroadenoma of the mammary gland and 142 normal controls were studied clinically, and vaginal smears from 177 of these women were cytologically examined to diagnose hormone disturbances associated with breast diseases. Twenty-eight patients with cancer, 31 with mastopathy, and 31 with fibroadenoma had a history of hepatobiliary

disease as compared to two (1.4%) of the control group. Of 177 patients, whose vaginal smears were examined cytologically, 32 had breast cancer, 131 fibrocystic mastopathy, and 14 fibroadenoma. A total of 86 or 48.6% (11 cancer and 75 dys hormonal hyperplasia) had increased estrogen levels, 43 patients (17 cancer and 26 dys hormonal diseases) had hypoestrogenism, and the remaining 48 (4 cancer and 44 dys hormonal diseases) had normal values. Thus, patients with dys hormonal diseases and breast cancer very often have hormone disorders which could accelerate the development of pathological processes in the breast.

3237 PATHOGENESIS OF HODGKIN'S DISEASE. (E.) Order, S. E. (Harvard Med. Sch., Boston, Mass.) and S. Hellman. *Lancet* (7750):571-573, 1972.

A hypothesis, based on clinical and laboratory observations, relates viral infection and host immunity to the pathogenesis of Hodgkin's disease. In this hypothesis, T cells (thymus-derived lymphocytes) are infected by a tumor-inducing virus causing a change in cell-surface antigen. Normal T cells begin to react against the virus-transformed cells in a fashion similar to a chronic graft-versus-host reaction and this interaction results in the production of neoplastic reticulum cells (histiocytes) which are the malignant component of the disorder. These neoplastic reticulum cells eventually appear as end-stage multinucleated Reed-Sternberg cells. This hypothesis is compatible with each of the salient clinical features of Hodgkin's disease, including primary site of the disease, histological pattern, preclinical status, loss of cell-mediated immunity, and prognosis.

3238 MUTATION AND CANCER: A MODEL FOR WILMS' TUMOR OF THE KIDNEY. (E.) Knudson, A. G., Jr. (Grad. Sch. Biomed. Sci., U. Texas, Houston) and L. C. Strong. *J Nat Cancer Inst* 48(2):313-324, 1972.

Statistical analysis of cases of Wilms' tumor supports a 2-mutation model previously reported for retinoblastoma. Comparison of data for familial, bilateral, unilateral, and unselected cases from 97 patients seen between 1944 and 1970 at the M.D. Anderson Hospital and Tumor Institute and from 58 previously published cases reveals that familial and bilateral cases have an early average age of diagnosis (two yr compared with a median age of 3-4 yr), while unilateral and unselected cases do not. Familial cases have a 21% incidence of bilaterality which is higher than that of unselected cases (5-10%) and a pattern consistent with autosomal dominant inheritance. These findings suggest that Wilms' tumor may be attributed to a 2-mutational model (i.e. 2 mutations are required in all cases), but, in approximately 38%, one mutation has occurred in the germinal line of a parent and is inherited. Persons acquiring this germinal mutant develop an average of one second mutation each, which gives rise to tumor. Approximate

mately 37% of gene carriers do not develop tumor, and 15% develop bilateral tumors. About 62% of cases of Wilms' tumor are nonhereditary, both of the mutations occurring in somatic cells. The previously reported association of Wilms' tumor with aniridia, hemihypertrophy, and genitourinary anomalies is fitted to the model. The familial pattern is noted to be similar to that of a delayed mutation; new germinal mutations may be attributable to a vertically transmitted tumor virus resembling the virus causing embryonal renal sarcoma in chickens.

- 3239 PATTERNS OF NUCLEIC ACID AND PROTEIN SYNTHESIS IN NORMAL HUMAN GASTRIC MUCOSA AND ATROPHIC GASTRITIS. (E.) Deschner, E. E. (Cornell U. Med. Coll., N.Y.), S. J. Winawer and M. Lipkin. *J Nat Cancer Inst* 48(6):1567-1574, 1972.

Gastric tissue obtained from biopsy of three patients with normal gastric mucosa and from 16 patients with histologically documented gastritis was incubated with ^3H -thymidine, ^3H -uridine, or ^3H -leucine. Incorporation was analyzed by autoradiography. In normal gastric mucosa, incorporation of precursors into DNA, RNA and protein was greatest in the neck and isthmus cells. However, in mucosa in various stages of atrophic gastritis, alterations in the gradients of precursor incorporation could be correlated with the severity of the gastric lesion. The earliest abnormalities were increased RNA and protein synthesis as well as DNA synthesis in surface epithelial cells of normal gastric mucosa. This gradient continued when the mucosa became lined with immature cuboidal cells and extended into the stages of increased atrophy and early intestinalization. During the period of severe atrophic gastritis, the intestinalized gastric mucosa was characterized by a labeling pattern seen in the normal small bowel--with DNA synthesis and greater RNA and protein synthesis in the lower portions of the glands.

- 3240 ORAL CONTRACEPTIVES AND PATHOLOGIC CHANGES IN THE BREAST. (E.) Taylor, H. B. (St. Louis U. Med. Sch., Mo.). *Cancer* 28(6):1388-1390, 1971.

A comparison is made of the histologic appearance of normal breast tissue and a variety of benign and malignant epithelial lesions in women using oral antiovolants and in age-matched controls. No histologic changes have been found that can reliably be attributed to the oral steroids by either light or electron microscopy. Reported changes in fibroadenomas and in carcinomas associated with oral contraceptive use have not been confirmed in studies utilizing controls. Additionally, no differences in the prevalence or in the age of patients at the time of diagnosis have been found for fibroadenomas, chronic cystic disease, or carcinoma. The lack of any demonstrable morphological changes in women's breasts related to oral contraceptive does not necessarily mean that these agents do not have a

carcinogenic or cocarcinogenic potential, but it makes such a possibility seem quite remote.

RECENT MORTALITY FROM CANCER OF THE CERVIX
IN THE UNITED STATES AND UNITED KINGDOM.

Higgins, I. T. T. (Sch. Public Hlth., U. of Michigan, Ann Arbor). *Lancet* (7734):1141-1143, 1971.

rates from cancer of the cervix in the United States in 1950-67 are compared with similar data for England and Wales. In the United States, unlike England and Wales, the crude mortality rates for cancer of the cervix have declined. The trend was noted both White and non-White women. Among White women there has been a consistent downward trend in all decennial age-groups. Among non-White women there has been a downward trend in each decennial age-group under 60 years. But among those aged 60-79 the rates in each ten-year group though fluctuating considerably from year to year, have shown no tendency to fall. Among White women the mortality-rates in the United States are higher than in England and Wales for women aged 25-39 and lower for those aged 60-74. Among women aged 40-79 the pattern is mixed, the rate being higher in the United States in the earlier years but lower in the later years on account of the cohort effect. In all decennial age-groups mortality from cancer of the cervix seems to have declined somewhat more in the United States than in England and Wales. A small degree of the differences noted may be attributed to differences in the way cancer of the cervix is coded and classified in the United States and United Kingdom.

CANCER OF THE ETHMOID BONE AND SOCIO-
OCCUPATIONAL CATEGORIES. (Fr.) Gignoux,

(P. Bernard and B. Gignoux. *Ann Otorhinolaryng* 20(9):1055-1056, 1971.

of malignant ethmoid tumors observed in a 15-yr study, 17 (30.7%) were found in wood workers. These included 12 cabinetmakers, three carpenters, one cooper, and one cooper. Ethmoid tumors in woodworkers appeared at a mean age of 58 yr, while these tumors appeared between 60 and 70 yr of age in other subjects. All of the woodworkers had been employed in their occupation since they were 16 yr old, indicating that the latent period for ethmoid tumors is about 40 yr. They are caused by occupational factors. Histological examination of the tumors showed that ethmoid tumors in woodworkers consisted of one reticulum-cell carcinoma and 16 glandular adenocarcinomas. The other ethmoid tumors included a greater variety of histological types: 15 spinocellular carcinomas, 12 glandular carcinomas, two basal-cell carcinomas, one papillary carcinoma, one cylindroma, one malignant plasmoma, and three lymphosarcomas. These findings confirm reports by English and American authors that ethmoid adenocarcinomas are an occupational disease of woodworkers.

COMPARATIVE HISTOLOGY OF GASTRIC CANCER IN
MIGRANT GROUPS IN ISRAEL. (E.) Munoz, N.

(Agency Res. Cancer, Lyon, France) and R. Steiner. *Israel J Med Sci* 7(12):1479-1487, 1971.

total of 278 cases of histologically confirmed gastric carcinomas diagnosed from 1960 to 1966 were

identified from files of the Cancer Registry of Israel. They were classified into one of three groups: intestinal type, diffuse type, or "others". The intestinal type of carcinoma was the most frequent type in the high-risk group (migrants from Europe, Morocco and Tunisia), representing 58.4% of all cases. The diffuse type accounted for 28.6%, and 13% were classified as "others". In the low-risk group (Israel and migrants from Iraq, Iran, Yemen and Greece), 45% were of the intestinal type and 50% were of the diffuse type. In both risk groups and both sexes, the ratio of intestinal to diffuse types of carcinomas increased with age. In both high- and low-risk groups, a significantly higher frequency of intestinal metaplasia was observed in the intestinal type than in the diffuse type of gastric cancer. Metaplasia associated with the diffuse type was graded as "mild" in 71% of the cases and no cases were graded as "severe", whereas in the intestinal type, 50% of the metaplasias were graded as "mild" and 50% as "moderate" or "severe". Seventy-nine of 110 cases studied for metastases had lymph node metastases of the same histological type as the primary tumor. When the primary tumor was a mixed type, however, there was a strong tendency for the most differentiated component (intestinal) to metastasize.

3249 STATISTICAL OBSERVATIONS ON CANCER AND
LEUKEMIA. (Fr.) Pizon, P. (Paris, France).
Rev Path Comp 71(815-816):243-246, 1971.

A statistical study was made of changes over five-year periods in the ratio of mortality from cancer and from leukemia to mortality from all causes in France between 1906 and 1968. During the period under study there were 3,133,199 deaths from cancer and 35,230,596 deaths from all causes. Cancer accounted for 3.97% of all deaths between 1906-1910 and for 18.39% in 1968. The mortality curve from cancer is increasing exponentially and will reach 57.8% by 2000 if it keeps increasing at the same rate. No distinction between cancer and leukemia as the cause of death was made in France until 1944, but the figures can only be considered reliable starting with 1953. There were 46,189 deaths from leukemia between 1953 and 1968 and 9,010,394 deaths from all causes. A detailed statistical analysis of leukemia data revealed that mortality from this cause is also increasing exponentially. The 1% mortality from leukemia extrapolated for 1979 will increase to 2.3% in 2000 if the present rate of increase continues. It is possible to infer from past evidence that leukemia did not appear among humans until towards the middle of the 19th century. It would seem that the experimental increase in mortality from cancer and from leukemia is due to the extension of the life span, which is also increasing exponentially with time and will reach 74 years in France in 2000. However, a comparison of the three exponential equations governing the three phenomena considered does not support this hypothesis. If the increase in life expectancy is a factor in the exponential growth of mortality from cancer and leukemia, then it is at most only a contributing factor.

- 3250 GESTATIONAL CHORIOCARCINOMA IN DENMARK: 1940-1969: A REAPPRAISAL BASED ON MODERN HISTOLOGIC CRITERIA. (E.) Mogensen, B. (Danish Cancer Soc., Aarhus, Denmark) and S. Olsen. *Acta Obstet Gynec Scand* 51(1):63-69, 1972.

Ninety-four cases of trophoblastic disease diagnosed in Denmark between 1940 and 1969 as choriocarcinoma (CHC) or "probably CHC" were reappraised and classified according to criteria laid down by the Armed Forces Institute of Pathology. Fifty of the cases were classified as CHC, 18 as invasive mole (IM), and 26 as other trophoblastic proliferations (OTP). Among the CHC patients, 30 died of generalized disease and one from postoperative complications. Eighteen patients (36%)--10 of them with metastases--recovered. Four of these patients were observed for 2-5 yr and 14 for more than five yr. One patient still has active disease. Forty-four patients suffering from IM (18) or OTP (26) were cured, including five with metastases. Based on the findings at the re-evaluation, the frequencies of IM and CHC were one case per 126,000 and 49,000 births, resp. The ratio of IM to CHC was 1 to 2.6. Compared with Norway and Sweden, Denmark seemed to have the lowest incidence of these diseases. During the yr 1943-1963, CHC accounted for approximately 0.03% of all malignant neoplasm in Danish females.

- 3251 TESTICULAR CANCERS IN CHILDREN: EPIDEMIOLOGIC CHARACTERISTICS. (E.) Li, F. P. (Nat'l. Cancer Inst., Bethesda, Md.) and J. F. Fraumeni, Jr. *J Nat Cancer Inst* 48(6):1575-1581, 1972.

To study risk factors for testicular cancers in childhood, an examination was made of 253 death certificates for U.S. children dying from these neoplasms in the period 1960-67, and 70 medical records from 14 institutions. Death rates exhibited an age peak in early childhood and a marked rise after puberty among whites. In contrast, persistently low rates occurred in black children and adolescents. Several reports have indicated a rising frequency of testicular tumors in young adults in recent decades, but mortality rates for children have remained stable. Embryonal carcinoma was the most common cell type reported in early childhood, and seminoma and choriocarcinoma were rare before puberty. Of the 70 children in the hospital series, 15 (21%) had inguinal hernia, undescended testis, or other genitourinary defects, a frequency which appears excessive. Since genitourinary defects also accompany Wilms' tumor, it is likely that the relationship between oncogenesis and teratogenesis is especially close in the developing genitourinary tract.

- 3252 A COMPARISON BETWEEN ENGLAND AND WALES AND SWEDEN IN THE INCIDENCE AND MORTALITY OF MALIGNANT SKIN TUMOURS. (E.) Lee, J. A. H. (Sch. Pub. Hlth., U. Washington, Seattle) and H. J. Issenberg. *Brit J Cancer* 26(1):59-66, 1972.

Although mortality from malignant skin tumors gen-

erally is similar in England and Wales and in Sweden, the incidence and death rate for malignant melanoma are higher in Sweden than in England and Wales. The melanoma incidence figures among males in England and Wales and in Sweden are 14.3 and 39.4 cases/million/yr, resp., while the same figures for females are 24.0 and 42.3 cases/million/yr, resp. These differences do not appear to be due to differences in statistical and medical care systems in the two regions. Rather, they are probably due to important genetic, occupational, or behavioral factors. It has been suggested that the high female melanoma incidence in England and Wales is caused by greater exposure of female limbs to sunlight in ordinary female dress. The increased male:female ratio for melanoma in Sweden compared to England and Wales is probably due to the fact that about twice as many males are employed in outdoor work (with attendant exposure to sunlight) in Sweden than in England and Wales.

- 3253 ASPECTS OF LUNG CANCER IN JAMAICA. (E.) Bras, G. (Dept. Path. Surg., U. West Indies, Jamaica), W. F. Whimster, A. L. Patrick and M. Woo-Ming. *Cancer* 29(6):1590-1596, 1972.

The incidence of lung cancer in the approximately one-half million population living in the parish of Kingston and St. Andrew of Jamaica--a tropical developing country--has been investigated for the years 1958-1970 inclusive. When compared--on an age-standardized basis--with figures published from other areas, Jamaica's figures appear to be substantially above those from Africa, but much lower than those from Britain and the United States. The incidence appears to be rising both in males and females. Clinical and pathologic data on 105 cases of lung cancer were obtained through the postmortem and surgical pathology services of the University Hospital of the West Indies, a 500-bed general hospital. The three main histologic types were equally represented at postmortem, but the squamous carcinoma type was more frequently seen in the surgical pathology material. The patients had an inadequate follow-up and were small in number; the data, therefore, did not allow an evaluation of the use of the W.H.O. histologic classification as to its prognostic significance. The duration of symptoms from onset to death or operation was generally less than six months. Figures presented here may be used as a base line from which future changes in the pattern of lung cancer in Jamaica may be measured.

- 3254 PRIMARY LIVER CARCINOMA IN ISRAEL. (E.) Costin, C. (Ministry Hlth., Jerusalem, Israel) and R. Steinitz. *Israel J Med Sci* 7(12):1471-1474, 1971.

Primary liver carcinoma (PLC), although rare in Israel (1.02% of all male and 0.38% of all female malignancies), shows considerable differences in its incidence and association with cirrhosis of the liver among various population groups in Israel. Two hundred and eleven cases were reported to the Israel Cancer Registry between 1960 and 1966. The male:female ratio was 3:1. In both males and females the majority of cases occurred between the ages of 55 and 64. Ninety percent were histologically con-

ed; almost 75% of these were hepatocarcinomas the rest consisted of cholangiocarcinoma, mixed carcinoma with cholangiocarcinoma, hepatoblastoma or chymal malignancies. World-standardized rates, calculated for ages 50 to 64 by sex and origin, suggest higher incidence in Jews from Balkan countries, Iran and Iraq and in non-Jews. The large number of cases confirmed by autopsy, compared with the generally low postmortem rate in Israel, and the expected findings of PLC at autopsy, point to an early diagnosis of this condition, especially among the groups where death occurs primarily at home - Jews and Jews originating from Asia or Africa). Association with cirrhosis of the liver was found in 1.2% of hepatocarcinoma in males, and in only 0.2% of females. However, there were striking differences in the different population groups, ranging from an association in 33.3% of male Iranian Jews in Israel to 75.0% of male Jews born in Iran.

VIRAL HEPATITIS, CIRRHOSIS, AND PRIMARY LIVER CANCER IN THE IVORY COAST: ETIOLOGICAL FACTORS COMPARED. (Fr.) Bertrand, E. (Hosp., Abidjan, Ivory Coast), M. Lebras, J. L. Leda and Y. Attia. *Concours Med* 93(51):8538-8540, 1971.

Epidemiological study of infectious hepatitis, cirrhosis, and primary liver cancer among hospital patients in Abidjan suggests that these three diseases are interrelated. Of patients hospitalized in various medical departments in Abidjan, 3.84% had infectious hepatitis, 3.80% cirrhosis, and 1.60% primary liver cancer. The morbidity of all three diseases is higher in males than in females. This is more pronounced for liver cancer: for each case in females there are 11 in males. While hepatitis was found primarily in patients 10-29 years old, cirrhosis and liver cancer were diagnosed primarily in patients 30-59 years old. The incidence of cancer decreased progressively in patients aged 30-59 years, while the incidence of cirrhosis had a second peak in patients 50-59 years old; this appears to be associated with alcoholism and cirrhosis. A study of the geographic origin of the patients suggests that cirrhosis is a sequel of infectious hepatitis and that cirrhosis is a precursor of liver cancer.

STUDIES ON THE FREQUENCY AND SPREAD OF GYNECOLOGIC MALIGNANT TUMORS WITHIN THE FRAMEWORK OF A DISTRICT HOSPITAL. (Ger.) Tilch, H. (Auerbach Dist. Hosp., Obergöltzsch, Germany), H. Schink, R. Treichel and F. Unger. *Zbl Gynaek* 124:94-100, 1972.

In a 15-year period, 503 malignant genital tumors (253 invasive carcinomas and 250 carcinomas *in situ*) were diagnosed in female patients at the Auerbach District Hospital. The invasive carcinomas included 147 cervical carcinomas (47.1%), 147 uterine carcinomas (33.7%), 72 ovarian carcinomas (16.5%), 7 vaginal carcinomas (1.6%), 3 vaginal carcinomas

(0.7%), 1 carcinoma of the fallopian tubes (0.2%), and 1 choriocarcinoma (0.2%). During this period the number of uterine and ovarian carcinomas tended to increase, but no decrease occurred in invasive cervical carcinoma. However, a significant increase occurred in the number of early cervical carcinomas with a significant decrease in the number of advanced cases, indicating that the early diagnosis of cervical cancer has improved. A tendency has also been noted for an increase in the number of early uterine carcinomas and a decrease in the number of advanced cases; the number of early ovarian carcinomas showed a slight tendency to increase.

3257 SURVIVAL OF BURKITT'S LYMPHOMA PATIENTS IN GHANA. (E.) Wosornu, J. L. (Burkitt's Tumor Project, Accra, Ghana), F. K. Nkrumah and I. V. Perkins. *Brit J Cancer* 25(3):479-486, 1971.

Of 141 suspected cases of Burkitt's lymphoma referred from all areas of Ghana between November 1965 and June 1969, the diagnosis of Burkitt's lymphoma was confirmed histologically in 60. Survival rate was determined in 50 treated and evaluable cases and was correlated with tumor stage. All patients were treated initially with cyclophosphamide. Second line drugs used for relapse and/or non-response were vincristine, methotrexate and cytosine arabinoside. The age distribution of cases was in agreement with previous reports (between four yr and puberty). The sex ratio was 1.6:1 (37 boys and 23 girls). More than half the patients had localized disease (stages I and II). The overall long term survival rate (52 wk or longer) was 38.5%. Stage I patients had the best prognosis (60% at 190 wk). No difference was seen between stage II and stages III and IV (disseminated) with 20 to 25% survival. No marked differences in survival rate between age groups was observed. All six stage I patients who died had large tumors. Eleven of 12 patients who had only an initial partial remission subsequently developed resistance to chemotherapy. Fifteen of 50 treated patients (representing all stages- five girls and ten boys) survived one yr or longer. Sixteen of the 50 patients were free of tumor as of December 1969. Thirteen of these had no tumor recurrence following initial treatment (seven stage I, one stage II and three stage III).

3258 GASTROINTESTINAL CANCER IN ISRAEL: WITH EMPHASIS ON FACTORS AFFECTING PATIENT SURVIVAL. (E.) Modan, B. (Chaim Sheba Med. Ctr., Tel-Hashomer, Israel) and H. Kallner. *Israel J Med Sci* 7(12):1475-1478, 1971.

Data on the incidence of and survival rates for gastrointestinal cancer diagnosed in Israel between 1955 and 1966 were collected and analyzed according to sex and birthplace. In general, gastric cancer was the most frequent (19.2 per 100,000 population) followed by cancer of the colon and rectum (15.4 per 100,000) and esophageal cancer (2.3 per 100,000). The male/

female ratio was 1.6:1 for both gastric and esophageal cancer and was close to 1:1 for large intestinal cancer. A comparison of the age-adjusted incidence rates of the main gastrointestinal cancer sites between European and Asian born patients revealed a ratio of 1.0 for the esophagus, 1.8 for the stomach and 3.2 for the colon and rectum. The European to African ratio was lowest (1.3) for gastric cancer but highest (3.3) for the colon and rectum. When age-matched groups were compared, the median survival of European born patients who underwent a curative type of operation for gastric cancer was almost twice that of the non-European patients who underwent surgery for gastric cancer. This difference in survival was limited to patients with regional metastases and was not observed with patients having distant metastases. European born patients had a higher frequency of papillary and well-differentiated adenocarcinoma while non-Europeans had a relatively higher frequency of anaplastic carcinoma. Thus, consideration of histologic grading along with ethnic group eliminated interethnic differences in the more malignant grades but not in the less malignant ones. It is concluded that ethnic differences do exist and that they are not caused by earlier diagnosis but are probably due to different disease types with a possible contribution of socioeconomic status.

- 3259 BRONCHIAL CARCINOMA IN YOUNGER PEOPLE.
(Ger.) Orban, E. (Clin. Lung Dis.
Zschadrass, Germany). *Z Erkr Atmungsorg* 135(3):
273-280, 1971.

Between 1954 and 1970, lung cancer was diagnosed in 75 patients (55 men and 18 women [sic!]) who were less than 45 years old. Of these 75 patients, 30 had lymph node metastases. The histological forms of lung cancer diagnosed were squamous cell carcinoma (28/75), small cell carcinoma (17/75), adenocarcinoma (11/75), polymorphocellular carcinoma (5/75), and a mucopidermoid tumor (1/75); a histological diagnosis could not be made in 3/75 patients. A comparison of these findings with others in the literature show that small cell carcinoma is significantly more common in patients less than 45 years old, while squamous cell carcinoma is significantly more common in older patients. The tendency to metastasis formation appeared more pronounced in the younger age group, but the difference was not significant. Surgery was performed on 72/75 patients. Of the 31 patients operated on more than five years before, 12 have survived for five years. The five year survival rate was higher in younger patients than in those over 45 years old; this may be due to the small number of younger patients and the increase with age of intercurrent causes of death. Case reports are presented for a 12-year-old boy with a "carcinoma adenomatousum psammosum" and a 23-year-old man with an undifferentiated small cell carcinoma; the latter patient had smoked 10 cigarettes/day for three years. It is difficult to attribute these cases of lung cancer to chronic exposure to exogenous factors.

- 3260 EPIDEMIOLOGY OF TUMORS OF THE NERVOUS SYSTEM IN ISRAEL. (E.) Hershowitz, E. (Hadassah, U. Hosp., Jerusalem, Israel), M. Fabianski and M. Alter. *Israel J Med Sci* 7(12):1491-1499, 1971.

The incidence of tumors of the nervous system in Israel was analyzed from records of the Central Tumor Registry for the years 1961-1966. A total of 1,354 tumors were recorded, and the annual incidence for this period was quite stable with a range of only 11.1 to 14.2 per 100,000 population. All tumors, except meningiomas were more prevalent in males than in females. The majority of tumors were more common in the latter half of life, with a peak frequency in the sixth and seventh decades. Neuroblastoma and medulloblastoma, however, occurred mainly as tumors of the young (under 20 yr of age). The overall age-corrected incidence of tumors of the nervous system was highest among immigrants from Europe and least common among immigrants from Africa. Native born Israelis has intermediate tumor frequency but were closer to Europeans, whereas Asian immigrants were closer to the African group. In each ethnic group, the brain was the most common tumor site, with peripheral nerve tumors occurring next in frequency. Spinal cord tumors were least common in all ethnic groups. Although the rates of most tumors were highest among European immigrants, gliomas and pituitary tumors had the highest incidence among native born Israelis. The relatively low incidence among Afro-Asian immigrants was not due to a decrease in the incidence of any one type of tumor. The best prognosis was associated with pituitary adenoma and craniopharyngioma, whereas glioma and neuroblastoma had the poorest prognosis.

- 3261 WORLD-WIDE DIFFERENCES IN THE SEX RATIO OF BRONCHIAL CARCINOMA. (E.) Belcher, J. R. (London Chest Middlesex Hosp., England). *Brit J Dis Chest* 65:205-221, 1971.

Information on the distribution and sex ratio of bronchial carcinoma was compiled from World Health Organization statistics for 1965, statistics from the University of Sendai, Japan, for 1965, publications from individual countries, and personal communications. The sex ratio of the incidence of bronchial carcinoma varied widely in different parts of the world, ranging from 13.5:1 (male:female) in Holland to 1:1 in Nigeria. In general, the national sex ratios of bronchial carcinoma incidence fall into two general groups. The countries of Europe, North America, Australasia and the European parts of the other continents had the highest sex ratios, and the rest of the world (non-European) the lowest. The incidence, proportion of cell types, and the site of growth also differed between European and non-European peoples. When European and non-European groups were considered separately, the sex ratio was not related to the total incidence of the disease as had been previously believed. When the incidence of bronchial carcinoma was expressed as a proportion of all malignant disease, the incidence in women was surprisingly constant

between 3.2 and 6%). However, wide variation occurred for males (7 to 39%) and the variation was correlated well with the observed world-wide variations in sex ratio of bronchial carcinoma. Statistical evidence indicated that the variation in sex ratio of bronchial carcinoma among countries was not due to differences in tobacco consumption. Variation in the sex ratio was also not due to different age structures of the different populations. The sex ratio was related neither to living standards nor to climate. With only one exception (citizens of foreign birth), the sex ratio of each ethnic group tended to follow the pattern of the country of origin no matter what was the country of residence. It is suggested that genetic factors may play a role in the etiology of bronchial carcinoma.

CANCER MORTALITY IN NEW YORK CITY FOR COUNTRY-OF-BIRTH, RELIGIOUS, AND SOCIO-ECONOMIC GROUPS. (E.) Seidman, H. (Amer. Cancer Society, New York, N.Y.). *Environ Res* 4(5):390-1971.

Cancer mortality in New York City from 1949 through 1963 is classified according to cancer site, sex, country-of-birth, religion and socioeconomic status in the non-Puerto Rican white population aged 25 to 64 years. In general, males classified according to country-of-birth showed high mortality for Catholics, an intermediate rate for Protestants and a low rate for Jews, with females classified similarly showing the opposite pattern. The mortality rates for Jewish males in the various country-of-origin groups were much closer than the rates for Jewish males and non-Jewish males in the same group; the same pattern was noted to lesser extent for Jewish females. Mortality and socioeconomic level varied inversely among males of all religions within a given country-of-origin group. The same relation was noted for Catholic and Protestant females. U.S.-born Jewish males of high socioeconomic status had a high mortality rate. Cancers of the breast, ovary, stomach and leukemias were especially prominent in this group.

CANCER MORTALITY AMONG ETHNIC GROUPS IN HAWAII. (E.) Kagan, A. (Honolulu Heart Center, Hawaii). *Israel J Med Sci* 7(12):1451-1454, 1971.

A comparison was made of cancer mortality rates among the various ethnic groups in Hawaii, using data based on death certificate summaries by the Hawaii State Health Dept. for the years 1957-1963. Among men, the highest cancer mortality was seen among the Japanese (225 per 100,000 population), closely followed by the Hawaiian/part-Hawaiians. Among women, the highest mortality was seen in the Chinese Hawaiian/part-Hawaiians (145 per 100,000). Japanese showed a higher than average mortality for cancers of the bronchus and lung, prostate and

ovary. A high mortality from cancers of the stomach, bronchus and lung, and breast and uterus was seen among the Hawaiian/part-Hawaiians. Chinese of both sexes showed higher than average mortality from cancers of the pharynx and buccal cavity, large intestine and rectum; and among Chinese women, from cancers of the lung, uterus and ovary. Filipino cancer mortality was characterized by low rates for all sites except those of the lymphatic and hemopoietic tissues, where the ratio was similar to that of other ethnic groups. Japanese men and women had an unusually high mortality from cancer of the stomach.

3264 LEUKOPLAKIA-AN EPIDEMIOLOGIC STUDY OF 1504 CASES OBSERVED AT THE TATA MEMORIAL HOSPITAL, BOMBAY, INDIA. (E.) Gangadharan, P. (Tata Mem. Ctr., Bombay, India) and J. C. Paymaster. *Brit J Cancer* 24(4):657-668, 1971.

The features of 1504 cases of leukoplakia seen from 1941-69 were studied and compared with cancer cases seen during 1950-59 at the Tata Memorial Hospital, Bombay. The oral cavity was the site of the disease in 96% of males and in 88% of females with leukoplakia. The buccal mucosa was the commonest site affected in all religious communities of Western India except among Parsis. The average age for oral leukoplakia cases among males (45.0 yr) was lower than that for oral cancer cases (50.3 yr); it was also lower for both leukoplakia (49.5 yr) and cancer cases (49.4 yr) among females. The male to female ratio of oral leukoplakia cases was 4.3:1, whereas for oral cancer the ratio was 2.3:1. The site distribution of oral leukoplakia and cancer differed among the different religious communities. Parsis, a majority of whom are nonsmokers and non-chewers of tobacco, had leukoplakia and cancer more often on the anterior two-thirds tongue than on the buccal mucosa. Hindus from Gujarat, who smoke often, had leukoplakia most commonly in the buccal mucosa, but cancer was more evenly distributed between the buccal mucosa, anterior two-thirds tongue and other sites. Statistical computation of the risk of malignant transformation indicated that males have a 4.8-fold higher risk of developing cancer when they have leukoplakia than the normal population, and females have a 7.1-fold higher risk of developing cancer in the presence of leukoplakia. Half of the leukoplakia cases which developed cancer at the same site did so within two yr, whereas those who developed cancer at a different site did so within four yr in 50% of the cases. It was felt that leukoplakia not associated with smoking habits had a greater chance of malignant transformation.

3265 GASTRIC CANCER IN ICELANDERS IN MANITOBA. (E.) Choi, N. W. (Manitoba Cancer Treatment Res. Fdn., Winnipeg, Canada), D. W. Entwistle, W. Michaluk and N. Nelson. *Israel J Med Sci* 7(12):1500-1508, 1971.

Previous analysis of reported deaths due to cancer in Manitoba between 1956 and 1965 had shown that first generation Scandinavian, Icelandic, Ukrainian and Jewish immigrants had a high risk of dying from gastric cancer. However, gastric cancer mortality among the descendants was much reduced. The Icelandic ethnic population was singled out because of the unusually high incidence of gastric cancer, and a dietary survey was conducted by questionnaire in order to determine the food items whose consumption differed between generations and to establish whether or not these changes were associated with the decreased cancer incidence in the descendants. Icelandic born Icelanders in Manitoba who were over 65 yr old (highest risk of gastric cancer) ate significantly more smoked or singed meats, blood pudding, skyr and salted or pickled meats than non-Icelandic born Icelanders. There was also a highly significant difference in the consumption of singed and smoked meats between the first generation immigrants and their descendants in Manitoba. Thus, the consumption of smoked and singed meats, which have been shown to contain high amounts of the carcinogen 3,4-benzopyrene is correlated with the high incidence of gastric carcinoma in immigrant Icelanders and the relatively lower incidence in their descendants.

- 3266 POPULATION TRENDS IN CIGARETTE SMOKING AND BLADDER CANCER. (E.) Hoover, R. (Harvard U. Sch. Public Hlth., Boston, Mass.) and P. Cole. *Amer J Epidemiol* 94(5):409-418, 1971.

An association between cigarette smoking and bladder cancer has frequently been demonstrated. The causal nature of the association has, however, remained in doubt. Because of this, trends in smoking habits and bladder cancer experience were examined for successive birth cohorts of men and women in the United States, Denmark and England and Wales. Increasing rates of the disease were observed in populations characterized by an increase in smoking among successive birth cohorts. The association is consistent in both sexes, different nationalities and in urban and rural groups. This makes it unlikely that the findings result from an association both of smoking and bladder cancer with a third variable.

- 3267 STOMACH AND LUNG CANCERS: INCIDENCE IN PIEDMONT WITH REFERENCE TO THE ENVIRONMENT. (E.) Anglesio, E. (Tumor Registry For Piemonte and Valle D'Aosta, Torino, Italy), A. P. M. Cappa, M. Panero and M. Pietroiusti. *Cancro* 24(1):17-24, 1971.

Data on the incidence of stomach and lung cancer obtained from the Cancer Registry of Piedmont, Italy, was analyzed for the years 1965-1966. The male:female ratio for both years was 4:1 for lung cancer and 2:1 for stomach cancer. For 1965-1966, 1398 cases of stomach cancer and 1095 cases of lung

tumors were recorded, representing 9% and 7.1%, resp. of the total number of tumors reported for all body sites. Gastric tumors were more frequent in people 55-80 yr of age with a peak age of 60-64 for males and 65-69 for females. Lung tumors were most prevalent between the ages of 60-64 for both sexes. The incidence of stomach tumors in small towns of mountain areas and hills was higher than the average regional values, whereas that for lung tumors was lower than the average regional values. Gastric tumors showed the highest incidence in the highly rural areas. Lung tumors were most prevalent in the large urban areas and of relatively low incidence in the rural towns. The incidence of lung tumors was highest and that of stomach tumors was lowest in the more industrialized areas. It was felt that atmospheric pollution might be an important factor in the development of lung tumors, and that poor socio-economic conditions and food intake patterns might play a role in the etiology of stomach cancer.

- 3268 SOCIAL TRAUMA IN THE EPIDEMIOLOGY OF CANCER OF THE CERVIX. (E.) Graham, S. (State U. New York, Buffalo), L. M. Snell, J. B. Graham and L. Ford. *J Chron Dis* 24(11):711-725, 1971.

Four hundred and forty-seven cases of cancer of the cervix were compared to 711 controls with other types of cancer and non-neoplastic diseases of other than genital organs from Roswell Park Memorial Institute. Cancer of the cervix cases were somewhat more likely to have been married two or more times, with 22.3 per cent having experienced at least two marriages as compared to 14.5 per cent of the controls. They were slightly more likely to have been married at a younger age. Thus, 26.1 per cent of the cases were married before the age of 19 as compared to 21.2 per cent for the controls. Only 3.1 per cent of the cases were first married over 30 yr of age as compared to 9.1 per cent of the controls. Cases of cancer of the cervix were of slightly lower socio-economic status and had had more pregnancies and live births than the controls. Further comparisons were made considering differences between cases and controls in age; size of family, including spouses, children, siblings, grandchildren, parents and other relatives; and whether the life events under consideration occurred among family members living in the subjects' or other households. Comparisons were made on the extent to which they and their family members had experienced death, divorce, illness, economic want, residential mobility, and feelings of being upset in the five yr prior to onset of the illness under consideration. The proportion of cases and controls experiencing various numbers of these incidents was also examined. No differences between cases and controls were found for any of these variables.

- 3269 PRIMARY INTRACRANIAL TUMORS IN THE ELDERLY. (E.) Cooney, L. M., Jr. (Boston U. Sch. Med., Mass.) and G. B. Solitare. *Geriatrics* 27(1):94-104, 1971.

detailed review of the anatomic findings in 1000 consecutive autopsies performed at the Yale-Haven Hospital yielded 497 patients with primary intracranial tumors, of whom 176 were 60 years of age or older. An examination of the hospital records of these elderly persons was undertaken to determine if a diagnostically significant clinical picture could be developed. Tumor symptoms were not commonly the vague complaints normally associated with aging and senility (i.e., mental status change, memory loss, disorientation). The rate of symptom onset provides a clear distinction between the slower growing meningiomas and the more rapidly progressing glioblastomas. The two lesions varied greatly in their effect on visual field defects and sensory defects, with 30% of glioblastoma patients having visual field defects and 28% having sensory losses; only 8% demonstrated these changes in the meningioma group. Special diagnostic procedures used include radioactive brain scanning, electroencephalography, cerebral arteriogram, contrast study, lumbar puncture and skull x-rays. Although clinical history and neurologic examination can often offer valuable diagnostic information, the most important element in establishing correct diagnosis remains a high index of suspicion.

ASBESTOS AND MESOTHELIOMA IN SCOTLAND: AN EPIDEMIOLOGICAL STUDY. (E.) McEwen, J. Dundee, Scotland), A. Finlayson, A. Mair and A. M. Gibson. *Int Arch Arbeitsmed* 28(4):301-311, 1965.

In 1965 an apparently low incidence of asbestos-induced mesothelioma had been recorded in Scotland, as compared to other areas of the United Kingdom. Since it seemed unlikely that the real incidence of mesothelioma would differ substantially, pathological reports for the years 1950-1967 were reviewed. Eighty substantiated cases were ultimately traced and detailed histories of residence, occupation and degree of exposure to asbestos were obtained from all available reliable sources. Exposure to asbestos was categorized as: 1) residential, 2) domestic and free time, and 3) occupational. This review of the records indicated that there had, in fact, been a larger number of mesothelioma cases than were initially reported as such. An increase in the number of recorded cases occurred from 1960 to date. Increased awareness in recent years of the link between asbestos exposure and malignancy has probably led to more patients with chest conditions and histories of exposure to asbestos being admitted to hospitals and their cases recorded.

INTESTINAL LYMPHOMA WITH MALABSORPTION IN MEDITERRANEAN POPULATIONS. (E.) Ramot, (Tel Aviv U. Med. Sch., Israel). *Israel J Med* 7(12):1488-1490, 1971.

Syndrome of small intestinal lymphoma with malabsorption has been shown to be relatively common among Arabs and Jews of Eastern and North African origin and correspondingly rare among Jews of European origin. Case material of 22 patients was

reviewed in an attempt to explain the etiology of the condition. Most of the patients belonged to the 15-30 yr age group, a distribution differing from that observed for similar cases in Western countries. The biopsy and autopsy material available could be divided into three main categories: 1) cases with massive plasma cell infiltration of the gut and lymph nodes without evidence of lymphoma (four cases); 2) plasma cell infiltration of the gut and malignant lymphoma in the mesenteric nodes (two cases), and 3) malignant lymphoma of the small intestine with a plasmacytic response in the uninvolved mucosa. Two of the cases from the first category had a protein abnormality manifested by the presence of a heavy chain of IgA. Contrary to previous reports, it was felt that the plasma cell response of the intestine was secondary to the lymphoma and was not the primary lesion. Examination of immunoglobulin levels in 99 persons from 11 families, including the families of the two patients with the heavy chain of IgA, provided no evidence for an immune deficiency state in patients with intestinal lymphoma. Unpublished reports have shown a high incidence of intestinal lymphoma and malabsorption among South African Negroes of the Cape region. The age distribution, clinical features and course of the disease were similar to those observed in the Mediterranean region. Patients from both regions belonged to an economically underprivileged population with a high incidence of gastrointestinal infections. Although genetic factors may play a role, environmental factors probably are most closely associated with the etiology of intestinal lymphoma with malabsorption.

3272 THE RELATIONSHIP OF INCIDENCE OF CERVICAL CANCER AND SOCIOECONOMIC STATUS IN SEVEN CITIES, 1959-1964. (E.) Christine, B. W. (Connecticut State Dept. Hlth., Hartford), W. H. Groff, T. H. Pitt and M. F. Chapple. *Conn Med* 36(2):80-83, 1972.

The relationship between the incidence of cervical cancer (*in situ* and invasive) and socioeconomic status based on data from seven combined metropolitan areas in Connecticut shows that the incidence of cervical cancer is inversely related to socioeconomic status. The lower the socioeconomic status of an area, the higher the incidence of cervical cancer. This inverse relationship is also seen for *in situ* and invasive cervical cancer taken separately. However, the inverse relationship is not constant when the cities are studied separately. In some, the rates after rising, reached a peak and then decreased in the lowest socioeconomic areas. It is believed that this reversal in the inverse trend is due to a lack of detection rather than a lack of cervical cancer among the very poor. Further studies now being conducted should help explain the differences in the cervical cancer rates observed.

3273 IDENTIFICATION OF HIGH RISK GROUPS IN BREAST CANCER. (E.) Zippin, C. (Cancer Res. Inst. Dept. Int. Hlth., U. California, San Francisco) and

N. L. Petrakis. *Cancer* 28(6):1381-1387, 1971.

In addition to a brief review of earlier work on the epidemiology of breast cancer, recently observed genetic, socioeconomic, and viral associations with this disease are discussed. Some of the associations, e.g., genetic, may be of a primary nature while others, such as socioeconomic status, are clearly indirect reflections of the operation of more fundamental factors. Most of the work referred to has assumed breast cancer to be a single entity. It is believed that more refinement in classification is necessary in attempting to study the etiology of this disease. It may be that when the various forms of breast cancer are sorted out, etiologic and epidemiologic relationships which still elude identification will emerge.

3274 CANCER MORTALITY IN 1962-66 AMONG POLISH MIGRANTS TO AUSTRALIA. (E.) Staszewski, J. (Inst. Oncology, Gliwice, Poland), M. G. McCall and N. S. Stenhouse. *Brit J Cancer* 25(4):599-610, 1971.

The 1962-66 cancer mortality of Polish migrants to Australia is compared with the cancer mortality prevailing in Poland and in Australia. Small numbers compelled the authors to limit their analysis to the most frequent cancer sites only. The main findings are: (a) stomach cancer mortality of Polish migrants to Australia is intermediate between the high mortality in Poland and the much lower one in Australia; (b) intestinal tract and breast cancer mortality of Polish migrants is displaced upwards, from the low Polish level to the much higher Australian one; and (c) lung cancer mortality of Polish male migrants does not differ distinctly from the mortality observed both in the country of origin and of adoption of these migrants. The presented findings are compared with the results of a similar study of Polish migrants to the U.S.

3275 THE ROLE OF MOTHER'S AGE IN THE RISK OF CHILDHOOD LEUKEMIA. (E.) Spiers, P. S. (Sch. Public Hlth., U. North Carolina, Chapel Hill). *Amer J Epidemiol* 94(6):521-523, 1971.

Maternal age as an etiologic factor in childhood leukemia is proposed. The plausability of this relationship is supported by the occurrence of other observable errors of meiosis which occur with increasing maternal age. Data indicate that the increased risk to leukemia is limited to children succumbing to the nonmyelocyte form of the disease between the fourth through eighth year of life. Partial correlation based on maternal age, order of birth and exposure to post-natal infectious agents are presented. Although they are considered statistically significant, these results are not considered to provide a definitive answer for the proposed role of the mother's age. Continued investigation into the problem is recommended.

3276 MALIGNANT TUMORS IN A PREDOMINANTLY BLACK HOSPITAL: A 20-YEAR RETROSPECTIVE STUDY AT FREEDMEN'S HOSPITAL, WASHINGTON, D.C. (E.) Kovi, J. (Howard U., Coll. Med., Washington, D.C.), M. Y. Heshmat and M. D. Gerald. *J Nat Med Assoc* 64(1):14-18, 1972.

The frequency of cases of malignant tumors in a major, virtually all-black, hospital in the United States is reported. Biopsy and autopsy records over a 20-year period (1951-1970) were reviewed, and all malignant tumors were classified according to primary site. Distribution of tumors by site, age and sex was tabulated. The following findings resulted: 1) no cases of Kaposi sarcoma and Burkitt tumor in any of the patients treated; 2) a low incidence in both sexes of tumors of the lip; 3) moderately high incidence of bronchial, tracheal and pancreatic tumors for both sexes; 4) high rates of occurrence of esophageal, gastric and intestinal tumors for both sexes, and 5) site of highest incidence to be cervix in females and prostate in males. The median age and diagnosis for cancer of the esophagus, rectum, larynx and kidney were significantly lower than the national average, especially so for females.

3277 CANCER OF THE OESOPHAGUS IN AFRICA: A SUMMARY AND EVALUATION OF THE EVIDENCE FOR THE FREQUENCY OF OCCURRENCE AND A PRELIMINARY INDICATION OF THE POSSIBLE ASSOCIATION WITH THE CONSUMPTION OF ALCOHOLIC DRINKS MADE FROM MAIZE. (E.) Cook, P. (M.R.C. Statistical Res. Services Unit, London, England). *Brit J Cancer* 24(4):853-880, 1971.

Three marked peculiarities exist in the occurrence of cancer of the esophagus in Africa; they are: 1) uneven geographical distribution; 2) changing pattern of frequency with time; and 3) the vagaries of the sex ratio. In all geographical areas the disease is more common among males than females. An unusually high frequency in specific geographical areas strongly suggests the influence of an environmental factor. Variations which exist in the sex ratio seem to indicate that the relevant contributing factor lies in the cultural environment. Extensive investigations show the present high frequencies developed from a negligible incidence 30 to 40 years ago. A detailed analyses based on registry data and personal interviews describing gradients of frequency in southern, central and east Africa compare the nutritional environmental and cultural habits of high risk populations to the no-risk groups. Further studies are planned in the southern area of the continent including chemical analyses of food and beverages for possible carcinogenic agents.

- 3291 A CYTOPHOTOMETRIC STUDY OF BENIGN AND MALIGNANT PHAEOCHROMOCYTOMAS. (E.) Lewis, P. D. (Royal Postgraduate Med. Sch., London, England). *Virchows Arch Abt B Zellpath* 9:371-376, 1971.

Feulgen-stained nuclear DNA content of 15 pheochromocytomas was measured cytophotometrically with an integrating microdensitometer and on the basis of these measurements the tumors fell into two distinct groups. Most nuclei in 12 of the tumors showed the same densitometer readings as normal diploid controls, although readings in some showed DNA values ranging from $4n$ to $40n$. The other three tumors, however, had a hyperdiploid or triploid mode and a smaller range of values. Case histories revealed that all three tumors with a hyperdiploid mode had metastasized, whereas none of the 12 tumors of the first group had done so. These results seemed to support the hypothesis that giant and atypical nuclei, which were related to a great variation in DNA content, were associated with tumor endocrine activity rather than malignancy. Since densitometry measurements appeared to separate metastasizing from benign tumors, the method might be of some practical and prognostic value.

- 3292 ACTIVITIES OF HEXOKINASE AND GLUCOKINASE IN VARIOUS HUMAN AND ANIMAL TUMORS. (Rus.) Parshin, A. N. (N. N. Petrov Res. Inst. Oncol., Leningrad, USSR) and L. A. Voronova. *Ukr Biokhim Zh* 43(5):605-608, 1971.

Human brain, stomach, and uterine tumors, rat rhabdomyoblastomas MOP and TsRM-1, and mouse hepatoma 22^a were studied. Hexokinase and glucokinase activities in tissue extracts and mitochondria were determined by a colorimetric method. The enzyme activities were measured in terms of 2-deoxyglucose-6-phosphate. The activities of hexokinase and glucokinase were 20 times higher in extracts from mouse hepatoma 22^a than in normal mouse liver and five times higher in the mitochondria of hepatoma 22^a than in normal mouse liver mitochondria. In contrast to this, the activities of both enzymes were 1/3 of normal values in human brain tumors and were not found at all in human uterine fibromyoma. A determination of the Michaelis constant showed that human stomach cancer and mouse hepatoma had higher affinities for the substrate (2-deoxyglucose) than healthy tissues; this was not true of human brain and uterine tumors and of rat rhabdomyoblastomas.

- 3293 SPONTANEOUS NEOPLASTIC TRANSFORMATION IN VITRO OF MOUSE WHOLE EMBRYO CELLS AND NEWBORN HAMSTER LUNG CELLS. (E.) Akagi, T. (Okayama U. Med. Sch., Japan). *Acta Med Okayama* 25(3):167-178, 1971.

Several characteristics of two mouse embryo cell lines (MWE-1 and MWE-2) and one hamster lung cell

line (NHLu-1) which spontaneously transformed *in vitro* are reported. The cells were separately prepared and subsequently maintained in a supplemented Eagle's medium. Growth rates were determined and the doubling time was found to range from 12 to 18 hrs. Autoradiographic techniques were used to determine generation time, pre-DNA synthesis gap, DNA-synthesis phase, post-DNA synthesis gap, and mitotic phase in all cell lines. Karyotyping of all cultured cells provided chromosome numbers and a marked aneuploidy was noted in all three cell lines. Inoculation of the cells into experimental animals resulted in tumor growth; histological examination of these tissues showed them to be usually fibrosarcomas.

- 3294 A STUDY OF ANDROGEN BIOSYNTHESIS PATHWAYS IN VIRILIZING TUMORS OF HUMAN ADRENALS. (Rus.) Smirnova, N. B. (Inst. Exp. Endocrinol. Chem. Hormon., Acad. Med. Sci. USSR, Moscow). *Probl Endokrinol* 17(5):16-21, 1971.

Formation of androgens was studied in virilizing adrenal tumors of two women with amenorrhea and hypertrophy of the clitoris and three girls with precocity, accelerated maturation of the skeleton and hypertrophy of the clitoris. Tumor tissues were incubated with radioactive pregnenolone and progesterone dissolved in methanol in doses 1-10 mcg/g tissue. After methanol was evaporated, 6 ml Krebs-Ringer solution (pH 7.4) with 200 mg% glucose was poured into each tube containing the tissue to incubate at 37 C for 30-60 min. Nonradioactive steroids were added to homogenates of the tissue with distilled water to effect steroid separation. Nonconjugated steroids were extracted by ethylacetate. The percentage of incorporation of labeled pregnenolone in 17α OH-pregnenolone and dehydroepiandrosterone exceeded the rate of incorporation of labeled pregnenolone into progesterone and 17α OH-progesterone in two women and one girl (12 yr old). This indicates formation of androgens through 17α OH-pregnenolone by way of pregnenolone \rightarrow 17α OH-pregnenolone \rightarrow androstenedione. In two children, incorporation of labeled pregnenolone in 17α OH-pregnenolone and dehydroepiandrosterone only insignificantly exceeded the incorporation into progesterone, 17α OH-progesterone. Together with free compounds, formation of dehydroepiandrosterone-, pregnenolone-, and testosterone-sulfates was seen in the tumors. The data lead to the conclusion that the transformation of pregnenolone into androgens occurs via 3β OH- Δ^5 -compounds and Δ^4 -3-ketocompounds.

- 3295 REGULATION OF TYROSINE- α -KETOGLUTARATE TRANSAMINASE IN RAT LIVER: REGULATION BY L-LEUCINE IN CULTURED HEPATOMA CELLS. (E.) Lee, K.-L. (Oak Ridge Natl. Lab., Tenn.) and F. T. Kenney. *J Biol Chem* 246(24):7595-7601, 1971.

The level of tyrosine transaminase (L-tyrosine:2-oxoglutarate transaminase, EC 2.6.1.5) in cultured hepa-

cells was markedly elevated by increasing the concentration of amino acids in the medium. The active component of the amino acid mixture was identified as L-leucine. D-Leucine, DL-trifluoroleucine, the deaminated product of leucine, α -ketoisocaproic acid, were inactive. At the optimum concentration (5 mM) L-leucine elicited an 8- to 10-fold increase in the transaminase level; the response was maximum at 12 to 14 hr and persisted for at least 24 hr. The half-life of the transaminase, estimated indirectly from kinetics of change in enzyme activity after addition or withdrawal of the amino acid and directly by isotopic-immunochemical methods, was six hr in the presence of 5 mM L-leucine and 12 hr after return of the cells to the basal medium (2 mM L-leucine). Pulse labeling experiments indicated that L-leucine also increased the rate of tyrosine transaminase synthesis by a factor of 3 to 4. Thus L-leucine increased the level of tyrosine transaminase by a dual effect on both synthesis and degradation of the enzyme. Combinations of L-leucine with the hormonal inducers hydrocortisone and insulin had additive effects on the transaminase levels. Hydrocortisone or insulin effectively induced the transaminase in leucine-free medium, and L-leucine further increased, in an additive manner, the enzyme activity of the cells which had been maximally previously induced by hydrocortisone or insulin. These results indicate that induction of the enzyme by either hydrocortisone or insulin is not mediated by leucine and imply that the mechanism of the induction of L-leucine is different from that effected by either of these hormones.

SYNTHESIS OF COAGULATION FACTORS BY A CLONAL STRAIN OF RAT HEPATOMA CELLS. (E.) Stad, H. E. (Dept. Microbiol., U. Oslo, Norway), Rydz and B. Johansson. *Exp Cell Res* 71:41-44, 1972.

A clonal strain of rat hepatoma cells (MHC) grown *in vitro* in a chemically defined medium was tested for its ability to synthesize blood coagulation factors. Human plasma from patients congenitally deficient in the respective factors was used in the assays. Factor VII activity in the culture medium increased linearly with time up to at least three days with a maximal rate of 20 U per mg deoxyribose/hr. The increase in factor VII could be prevented by actinomycin D or cycloheximide indicating that synthesis was endogenous. Warfarin slightly reduced the rate of appearance of factor VII activity in the culture medium. Treatment of cells with vitamin K increased the rate of appearance and also the total activity of factor VII. In addition, a procoagulant activity was detected in the culture medium which could correct the defect of factor V deficiency plasma. This activity could be removed by BaSO_4 treatment and could be eliminated by gel filtration, suggesting that this factor was not identical with Factor V which was unaffected by such treatment. Factor V-like activity was not enhanced by treatment with vitamin K. Neither thrombin, factor II, or antithrombin III activity was found in cells or culture medium.

3297 ETIOLOGY AND CLINICAL PICTURE OF PRIMARY LIVER CANCER. (Rus.) Fishzon-Ryss, Yu. I. (S. M. Kirov Mil.-Med. Acad., Leningrad, USSR) and I. A. Mogilevskaya. *Terapev Arkhiv* 43(10):14-18, 1971.

A study was made of 120 patients (69 males and 51 females, 111 over 40 yr old) with primary liver cancer diagnosed by autopsy or biopsy findings. The most common associated diseases were inflammatory alterations of the liver and bile ducts (45.0%) followed by alimentary disorders (including alcoholism) in 32.6%. Alcoholism was found in 22.5%, histories of infectious hepatitis in 12.5%, cirrhosis in 9.2%, malaria in 11.7% (associated with cirrhosis in 2.5%), gastrointestinal dystrophy in 10.1%, closed liver trauma in 5%, and surgical removal of other malignant tumors in 4.2%. Three clinical forms were distinguished: typical or hepatomegalic (36.6%), cirrhosis-like (23.3%), and masked (40% with metastases and complications). In most cases, patients survived 4-6 months from the onset of symptoms, but in some cases the patients survived for 1-1.5 yr.

3298 CARCINOGENESIS BY VAGINAL TRANSPLANTS FROM OVARIETOMIZED, NEONATALLY ESTROGENIZED MICE INTO OVARIETOMIZED NORMAL HOSTS. (E.) Takasugi, N. (Fac. Sci., Okayama U., Japan). *Gann* 63(1):73-77, 1972.

Female C57BL/Tw mice were given s.c. injections of 20 μg 17 β -estradiol or 0.02 ml sesame oil (controls) for ten days beginning at birth. Estrogen-treated mice were ovariectomized at 55-65 days of age and killed at 796-831 days of age. Vaginas were dissected and transplanted under the abdominal skin of 18 female mice which were ovariectomized at the time of transplantation. Vaginas in estrogen-treated donors showed a hyperplastic epithelium. By two months after transplantation of hyperplastic vaginas into ovariectomized mice, two grafts had transformed into basal cell carcinoma with a small number of squamous cells. In grafts recovered from the remaining 16 mice 127 days after transplantation, the epithelium was hyperplastic. No carcinoma or hyperplasia were seen in vaginal grafts implanted in ovariectomized mice from donors which had not received estrogen. Cancerous vaginal transplants from ovariectomized recipients were excised and transferred for a third or fourth time to new ovariectomized recipients. Two of four mice receiving the fourth transfer and killed 70 days after transplantation showed metastatic nests of cancer cells in mesentery and pancreas.

3299 GROWTH OF SARCOMA 180 IN SPLENECTOMIZED MICE BEARING DIFFUSION CHAMBERS CONTAINING SPLEEN OR TUMOR CELLS. (E.) Rumi, L. (Nat'l. Acad. Med., Buenos Aires, Argentina), C. D. Pasqualini and S. L. Rabasa. *Europ J Cancer* 7(6):551-555, 1971.

Murine sarcoma S-180 was implanted s.c. into BALB, AKR, A and Rockland mice; the tumor was 100% lethal in BALB mice, while a spontaneous, complete and permanent regression of the tumor was seen in some of the mice of the other strains. Splenectomy performed seven days before tumor challenge increased tumor regression in mice of all four strains, 28-100% of splenectomized mice surviving tumor challenge. Splenectomy performed after tumor challenge also increased regression of tumors. Hepatectomy did not increase the survival of mice implanted with S-180, and with s.c. transplantation of fibrosarcoma cells seven days after splenectomy no increase of survival of splenectomized mice over non-splenectomized mice was seen. This indicated that only S-180 could evoke a stimulatory effect of splenectomy on tumor regression. The response to S-180 transplants of splenectomized BALB mice, bearing i.p. 0.22 μ filter diffusion chambers implanted at or seven days before S-180 challenge and containing either syngeneic spleen cells or S-180 cells, was observed. The trend towards tumor regression in splenectomized mice was reversed by the presence of diffusion chambers containing spleen cells or S-180 cells. This reversal of tumor regression by diffusion chambers was not seen in mice implanted with chambers containing cells from a different tumor, or in mice implanted with empty chambers. It was suggested that S180 in diffusion chambers introduced before S-180 challenge elicited circulating antibody production. These antibodies would then be available before the development of an effective cellular immune response to S-180 challenge, and would foster progressive tumor growth.

- 3300 TUMOUR GROWTH AFTER INTRAVENOUS, INTRAPERITONEAL AND SUBCUTANEOUS INJECTION OF SYNGENEIC MONODISPersed TUMOUR-CELL SUSPENSION. (E.) Boeryd, B. (Dept. Pathol., U. Göteborg, Sweden), P. M. Lundin and K. Norrby. *Europ J Cancer* 7(6):557-559, 1971.

CBA and C57BL/6J mice were given injections of 3-methylcholanthrene-induced sarcoma cells and spontaneous melanoma cells, resp. Routes of injection were i.v. in the tail vein, i.p. or s.c. The number of tumor takes produced by each mode of injection was observed. For tumors to grow after i.v. injection 10^2 - 10^4 times as many cells were needed as were needed after i.p. or s.c. injection. It was thought that more tumor cells were needed in i.v. injections because tumor cells in the vascular system were placed in a less suitable micro-environment than cells in the peritoneal cavity or in s.c. tissue. Specifically, close proximity of tumor cells would be less likely to be achieved in the vascular system than in other regions.

- 3301 PHYTOSTEROLS IN NORMAL AND TUMOR-BEARING RATS. (E.) Nes, W. R. (Dept. Biol. Sci., Drexel U., Philadelphia, Pa.), N. S. Thamp and J. T. Lin. *Cancer Res* 32:1264-1266, 1972.

Gas-liquid chromatography and mass spectroscopy were used to examine sterols in normal and Morris hepatoma-bearing rats. Two typical phytosterols, 24-methyl- and 24-ethylcholesterol, were found to make up about 1.1% of total sterols in both normal and tumor-bearing rats. A hepatoma-bearing rat was given i.p. injections of 22,23- ^3H -24-ethylcholesterol to examine deposition of the phytosterols in tissue. Neutral lipid from liver contained 1.5% of injected radioactivity, hepatoma contained 0.25%, and the remaining carcass contained 13%. Similar injections of cholesterol-4- ^{14}C were given to another rat. The amount of label found after two wks in the liver was 2.3% of the amount injected, while the amount of label in the tumor was 0.90%, and the amount in the remaining carcass was 82%. The radioactive 24-ethylcholesterol did not lead to incorporation of label into cholesterol or into any other observable sterol. 24-Methyl- and 24-ethylcholesterol are usually the dominant sterols of higher plants. Probably, these phytosterols seen in the rats were of dietary origin.

- 3302 LEUKOCYTE ADENOSINE DEAMINASE PHENOTYPES IN ACUTE LEUKEMIA. (E.) Bloom, G. E. (U. Florida Coll. Med., Gainesville). *Cancer* 29(5):1357-1360, 1972.

Peripheral blood and bone marrow samples were taken from 20 patients with leukemia; samples were sedimented and the leukocyte-rich portions were disrupted by sonication and subjected to electrophoresis. The electrophoretic patterns of 14 enzyme systems in the leukemia patients were compared. No altered electrophoretic mobilities compared to normal leukocyte patterns were seen for any enzyme except adenosine deaminase (ADA). In blood and bone marrow of six patients with acute myelomonocytic leukemia, and in one patient with acute myelogenous leukemia, there was an extra band of ADA activity proximal to the normal appearing bands of ADA activity. In acute lymphoblastic leukemia patients no alterations in ADA electrophoretic mobility were seen.

- 3303 CELL POPULATION KINETICS OF A SPONTANEOUS RAT TUMOUR DURING SERIAL TRANSPLANTATION. (E.) Steel, G. G. (Inst. Cancer Res., Belmont, Surrey, England), K. Adams, J. Hodgett and P. Janik. *Brit J Cancer* 24(4):802-812, 1971.

Studies were made on the growth and cell population kinetics of a spontaneous mammary fibroadenoma in an inbred August strain female rat, and of ten successive s.c. transplantation passage in syngeneic hosts. The tumor volume doubling time, determined from vernier caliper measurements, decreased from about 30 days in the primary tumor to 1.7 days in the tenth transplant. Estimates of the duration of the different phases of the cell growth cycle based on *in vivo* ^3H -thymidine pulse-labeled mitotic wave curves showed that the accelerated volume doubling was accompanied by a considerable shortening

the S and G₁ phases without a change in the proportion of time spent in S. There was also a reduction in the apparent extent of cell loss and a considerable decrease in the fraction of growing cells. Density measurements of Feulgen-stained tumor sections of successive passages indicated a gradual shift in chromosome number from hyperdiploid to hyperdiploid. This change was accompanied by increases in cell density (nuclei per unit area of section) and mean nuclear diameter. Also, the proportion of the tumor which consisted of fibroblasts, macrophages, polymorphs and most cells decreased with serial passage.

CHROMOSOME STUDIES IN EXPERIMENTAL MOUSE GLIOMAS. (E.) Yamashita, J. (Natl. Inst. Cancer, Mishima, Shizuoka-ken, Japan). *Gann* 63(2):187, 1972.

Chromosome studies were conducted on different populations of 3-methylcholanthrene-induced gliomas in BALB/c mice and in one C57BL/He mouse. Growing tumor cells were arrested *in vivo* in metaphase by the colchicine arrest technique. Tumor tissue was excised, trypsinized and prepared for chromosome analysis. The tumors were histologically classified as gliomas and the diagnosis confirmed by analysis of their aldolase activity patterns. All three tumors showed considerable variations in karyotype with no common specific chromosomal changes. After a few passages *in vivo*, all three lines tended to become tetraploid and then hypotetraploid. In the BALB/c glioma, 98% of the cells in the sixth transplant generation contained one metacentric marker chromosome. Although cells from the glioma induced in C57BL/He mice contained a variety of centric and minute markers, the presence of two metacentric marker chromosomes in each cell was a relatively constant feature. Although the karyotype of all three tumors was followed with serial transplantation, they could not easily be followed.

IN VIVO KINETICS OF NUCLEIC ACIDS IN HUMAN CANCER CELLS. (Fr.) Duprez, A. (U. Hosp. Nancy, France) and M. Bessot. *Ann Med Nancy* 8:329-336, 1969.

The method is described for determining *in vivo* the rate at which ³H-thymidine and ³H-uridine are incorporated into DNA and RNA, respectively, in tumor cells. This method involves intraarterial injection of the tumor during surgery for one hr with a radioisotope. After serial sectioning of the tumor tissue two successive sections were taken, one for autoradiography and the other for digestion with DNase or RNase. Extraction was performed in a liquid scintillation counter and counting was taken. By taking into consideration the rate of perfusion, the quantity of radioactivity injected, and planimetric measurements of the tissue

section, the radioactivity in a unit of volume of tissue is calculated.

3306 INHIBITION OF A SPECTRUM OF ANIMAL TUMORS BY DIETARY ZINC DEFICIENCY. (E.) DeWys, W. (U. Rochester Sch. Med. Dentistry, N.Y.) and W. Pories. *J Nat Cancer Inst* 48(2):375-381, 1972.

Zinc deficiency had previously been shown to inhibit growth of Walker 256 carcinosarcoma, a rapidly dividing solid tumor, in rats. To ascertain whether tumor inhibition is a general effect of zinc deficiency, the growth of the more slowly dividing, solid, Lewis lung carcinoma in male C57BL/6 mice of several ascites tumors in CDF male mice was studied in zinc-deficient animals. Growth of Lewis lung tumor transplants in mice pretreated for 11 days with a zinc-deficient diet was markedly reduced compared with tumor implants in control mice on a zinc-supplemented diet. Mice on the deficient diet also showed a delay in appearance of palpable tumors, and survival, although prolonged, was probably limited by the adverse effects of zinc deficiency. Pretreatment with a zinc deficient diet also significantly prolonged survival of mice inoculated with L5178yf and L1210 but not with P388 mouse leukemia. Survival of the leukemic mice was much shorter than survival of Lewis lung tumor bearing mice on the zinc deficient diet. To investigate whether this apparent difference was related to the mode of tumor growth (i.e. ascitic vs. solid), the effects of zinc deficiency were compared in both the ascites and solid tumor forms of Walker 256 carcinosarcoma in male Sprague-Dawley rats. Survival was prolonged to the same extent for the two forms, apparently excluding the possibility that the results were due to differences in the site of tumor growth. It is concluded that tumor inhibition is a general effect of zinc deficiency, irrespective of cell type, cell growth rate, or site of growth.

3307 ESTROGEN PRODUCTION BY TROPHOBLASTIC TUMORS IN TISSUE CULTURE. (E.) Pattillo, R. A. (Med. Coll. Wisconsin, Milwaukee), R. O. Hussa, W. Y. Huang, E. Delfs and R. F. Mattingly. *J Clin Endocrinol Metab* 34(1):59-61, 1972.

Established cultures (BeWo and Jar lines) of pure trophoblastic cells derived from human gestational choriocarcinomas were incubated (eight to 20 hr) with either of two androgens, androst-4-ene-3,17-dione-1,2-³H (H-Δ⁴) or dehydroepiandrosterone-7-³H (³H-DHEA). Labeled estrogens synthesized by the cells during the incubation period were separated from neutral steroids and analyzed by reverse phase and direct phase partition chromatography on Celite columns. Identity of labeled estrogens was confirmed by isotope dilution and derivative formation. Estrone (E₁) and 17-estradiol (E₂) were synthesized from ³H-Δ⁴ in Jar cells, and from ³H-Δ⁴ and ³H-DHEA

in BeWo cells. When $^3\text{H}-\Delta^4$ was precursor, E_2 production (135-14,200 ng/g cells/day) exceeded that of E_1 (43-2120 ng/g cells/day) by two to ten times in both cell lines. It was concluded that potential steroidogenic pathways for estrogen synthesis similar to those of the normal placenta are retained in malignant trophoblastic tumor cells *in vitro*.

- 3308 REGULATION OF ADENOSINE 3':5'-CYCLIC MONOPHOSPHATE PHOSPHODIESTERASE ACTIVITY IN FIBROBLASTS BY INTRACELLULAR CONCENTRATIONS OF CYCLIC ADENOSINE MONOPHOSPHATE. (E.) D'Armiento, M. (Nat'l. Cancer Inst., Bethesda, Md.), G. S. Johnson and I. Pastan. *Proc Nat Acad Sci USA* 69(2):459-462, 1972.

Cyclic AMP-phosphodiesterase is present in various mouse fibroblasts. Contact-inhibited 3T3 cells contain two forms of the enzyme, one with a K_m of 2.5 μM and the second with a K_m of 71 μM . As 3T3 cells grow to confluency and cAMP concentrations rise, the activity of the first enzyme increases, whereas that of the second is unchanged. A line of SV40-transformed 3T3 cells with low cAMP concentrations also has low levels of the cAMP-phosphodiesterase with a K_m of 2.5 μM . Treatment of 3T3 and SV40-transformed 3T3 cells with dibutyl cAMP and theophylline increases cAMP-phosphodiesterase accumulation. This accumulation is blocked by cycloheximide and actinomycin D. The newly formed enzyme resembles the higher affinity enzyme present in unstimulated cells, since it has a K_m of 1.2-2.0 μM , and is stimulated by snake venom. In L cells in which cAMP concentrations are elevated by treatment with prostaglandin E_1 , cAMP phosphodiesterase also accumulates. It is concluded that intracellular concentrations of cAMP regulate the synthesis of cAMP-phosphodiesterase, and that cAMP functions as an inducer of the enzyme.

- 3309 THE FLUORESCENT PATTERN OF NORMAL CHROMOSOMES IN BIOPSIES OF MALIGNANT LYMPHOMAS, AND ITS COMPUTER DISPLAY. (E.) Fleischmann, T. (Inst. Genetics, U. Lund, Sweden), T. Gustafsson, C. H. Hakansson and A. Levan. *Hereditas* 70:75-88, 1972.

Tumorous lymph nodes from seven patients with histologically diagnosed Hodgkin's disease, lymphosarcoma, reticulum cell sarcoma and malignant lymphoma of uncertain type were extirpated from the neck, from the axilla and from the inguinal regions and short term cultures made. Normal-looking chromosomes from a total of 150 metaphases were stained by a modified fluorochrome procedure using atetrin, and densitometer scans of well-stained preparations were further analyzed by computer. Results were presented as photomicrographs, as contour maps of isobrightness curves and as three-axis diagrams for each of the 22 somatic and two sex chromosomes. Banding patterns of "normal" tumor chromosomes and previously published fluorescence patterns of

normal leukocyte chromosomes were similar. The only deviation from normality in the "normal" tumor chromosomes was a more pronounced variation in size sometimes noticed both among the different pairs and between the homologues of each pair.

- 3310 A CYTOGENETIC ANALYSIS OF HUMAN SEMINOMAS. (Rus.) Lelikova, G. P. (Inst. Exp. Clin. Onkol. Moscow, USSR), A. V. Laskina, A. F. Zakharov and E. E. Pogonyants. *Vop Onkol* 17(11):20-28, 1971.

Human seminomas (18) were karyotyped to determine the extent to which the different groups of chromosomes are responsible for variability in the karyotype and to clarify the correlation between histological characteristics of the tumors and their karyotype. The modal classes of cell populations in these tumors were 3n-6n, indicating that human seminomas are heteroploid. A comparison of the number of chromosomes and tumor morphology showed the existence of two groups: tumors characterized by triploid sets of the chromosomes with differentiated structures and tumors made up of highly polymorphic cells which had more than four sets of chromosomes. There was a tendency for the number of chromosomes in seminoma cells to increase as cell differentiation decreased. Thirteen of 18 seminomas had marker chromosomes. In three cases marker chromosomes were characterized by extreme distention of the centromere region in small submetacentric or acrocentric chromosomes. Most frequent were long subtelocentric chromosomes, which varied in size. An analysis of seminoma chromosomes by groups (A to G) also showed heterogeneity of the cell populations. A statistical study made of the seminoma chromosomes revealed that the average number of chromosomes per cell differed greatly in different groups, ranging from 59.6 to 136.1. In all 12 tumors studied, the number of chromosomes was decreased in group B and increased in group C; they were decreased in Group E in 11/12. In other groups of chromosomes, the numbers fluctuated greatly.

- 3311 ISOENZYMES OF ISOCITRATE DEHYDROGENASE IN CYTOPLASM OF HUMAN CANCER CELLS. (E.)

Opher, A. W. (VA Hosp., Fort Howard, Md.), J. W. Leonard, Jr. and J. M. Miller. *Exp Med Surg* 29(1-2): 15-18, 1971.

Homogenates of tissues obtained from histologically diagnosed squamous cell carcinoma from esophagus, larynx, penis and tongue were assayed for nicotinamide-adenine-dinucleotide phosphate (NADP)-dependent isocitrate dehydrogenase (ICDH) activity by a spectrophotometric method. In addition, isoenzymes of ICDH were analyzed by electrophoresis and the fractions were quantitated by densitometry. All four carcinomas tested contained "enhanced" amounts of total ICDH activity ranging from 180 U for penis to 674 U for esophagus. Whereas normal control tissue contained the expected three isoenzyme fractions, six fractions possessing ICDH activity were recog-

in the four carcinomas. ICDH from tongue
ted as one fraction. Each of the other three
nomas contained four bands although the percent-
distribution and migration pattern differed
them. The appearance of four fractions in
carcinomas was not consistent with the proposed
ic subunit structure of ICDH, thus supporting
upposition that the carcinoma may change the
e of the various fractions and alter their
ity.

ENERGY EXCHANGE IN EHRLICH'S TUMOR CELLS AND
Nk/Ly LYMPHOMAS IN THE PROCESS OF TUMOR
(Rus.) Kaz'min, S. D. (Kiev Res. Inst.
lin. Oncol., USSR) and N. N. Mel'nikova. *Vop*
18(3):66-70, 1972.

y was made of glucose and oxygen requirements
anges in two types of ascites tumors: Ehrlich's
/Ly lymphoma. The tumor cells were injected
nto hybrid male mice, and the glucose and
uptake was determined by the rise in their
trations in cell-free ascites fluid. Glucose
etermined by a fermentation method, and the
concentration by polarography, using
inum microelectrode inserted into the peritoneal
of the animal. Kinetic curves of tumor growth
eir corresponding polarographic curves show
ponential character of the tumor growth in the
l period, with a decreased of growth rate in
periods in both tumors. The exponential phase
four days from the tumor inoculation, when
cells were in the peritoneal cavity. Oxygen
into the tumor was low, being 2.6 $\mu\text{M/hr/mouse}$,
 10^6 cells were present in the peritoneal
This uptake will support respiration for a
a of 30×10^6 cells. Thus, hypoxia occurs in
stages of tumor development. This state is not
ed in the rate at which tumor cells multiply,
remains high for four days. With the develop-
hypoxia, glycolysis intensifies, compensating
iciency in ATP resynthesis during respiration.
e of glucose uptake by the plasma was 49 $\mu\text{M/hr}$ /
which could satisfy the glucose requirement
at 200×10^6 cells. Thus, all subsequent tumor
must occur against a background of glucose
iciency. ATP resynthesis curves in Ehrlich's
cells show that a sharp decrease occurs in the
respiration and that more than 85% of the ATP
nthesized in the glycolytic cycle. Thus, a
ed rate of energy exchange and reduced glycol-
e the main factors in reduced multiplication
r cells in the later periods.

CARBOHYDRATE METABOLISM IN THE NEOPLASTIC
PROCESS. (Rus.) Miloslavskii, I. M.
an Inst. Postgrad. Med., Kharkov, USSR),
yshlevaya and YA. M. Buntser. *Vop Onkol*
4-78, 1972.

Carbohydrate metabolism was studied in 646 patients
(272 male and 374 female) with various localized
tumors (220 stomach, 127 brain, 100 breast, 100
lung, 78 rectum, and 21 large intestine) by glucose
tolerance tests. The carbohydrate metabolism was
also studied by the same method in 50 ulcer patients,
35 with benign mastopathies, 237 with inflammatory
diseases of the central nervous system, and 80 nor-
mal subjects. Disturbances in carbohydrate metabo-
lism occurred frequently in cancer patients (10-55%).
The disturbance was more pronounced in cancer of the
brain (55%), stomach (55%), and intestine (37%).
Diabetes-like curves were seen with about the same
frequency in patients with various tumors of the
gastrointestinal tract (24-29%). Hyperglycemic and
glycosuric disturbances were seen in brain cancer
patients. Disturbances in carbohydrate metabolism
became more pronounced as tumor growth advanced.
Functional and morphological disturbances were
observed in the pancreas (especially beta cells)
of subjects who had died from malignant neoplasms.
Administration of easily assimilated monosaccharides,
small divided doses of insulin, and the use of
anabolic preparations (nerobol, methandrostenolone)
prevented disturbances in carbolism in 91 operated
patients with visceral tumors.

3314 ROLE OF 3',5'-ADENOSINE MONOPHOSPHATE IN REGULATION OF MORPHOLOGY AND GROWTH OF TRANSFORMED AND NORMAL FIBROBLASTS. (E.)

Johnson, G. S. (Nat'l. Cancer Inst., Bethesda, Md.)
and I. Pastan. *J Nat Cancer Inst* 48(5):1377-1387,
1972.

Morphology and growth properties of various normal
and virus-transformed mouse and hamster fibroblasts
were altered when the cells were grown in the
presence of 1.2 mM N^6, O^2' -dibutyryl 3',5'-adenosine
monophosphate (dbc-AMP). During treatment with
dbc-AMP, the cell body and processes were elongated.
Cells became spread out and flatter, and the area of
cell surface in contact with the substratum was
greatly increased. Although morphologic changes
were seen with all cell lines tested (including
Swiss/3T3, BALB/3T3, and these two lines transformed
by polyoma virus, murine leukemia and sarcoma
viruses, and SV40), the changes observed in the
transformed lines were not so extensive as those
seen in the untransformed ones. L-2071 cells, a
line that grows on a chemically defined, protein-
free medium, and BHK-21 cells growing in monolayers
also showed a significant response to dbc-AMP. An
exception to the lack of great response in SV40-
transformed cells was one transformed BALB/3T3 line.
The extensive vacuolization of this line was also
reduced by dbc-AMP. Dibutyryl c-AMP decreased the
growth rate of all cell lines; the effect was
potentiated by 1 mM theophylline. The treatment
decreased by seven-fold the saturation density
of 3T3 cells but did not markedly decrease the
saturation density of the non-contact-inhibited
transformed cells, even in the presence of theo-
phylline.

- 3315 CHROMOSOMAL ANEUPLOIDY DURING THE COURSE OF ACUTE LYMPHATIC LEUKEMIA IN A SUBJECT WITH TRISOMY 21. (It.) Crisalli, M. (G. Gaslini Inst., Genoa, Italy), R. Monteverde and F. Dagna-Briccarelli. *Minerva Pediat* 23(43):1791-1797, 1971.

A girl with trisomy 21, diagnosed at 12 months, developed acute lymphatic leukemia at 3.25 years. At the onset of leukemia, the only chromosome abnormality was the extra G chromosome. Administration of cortisone and antileukemic agents (unspecified) for one month induced a partial remission which lasted for six months with maintenance therapy. During this remission other abnormalities developed in the karyotype. These included the loss of a C group chromosome, either alone or associated with the loss of a D group chromosome; the loss of a D group and a G group chromosome; and the loss of a C group chromosome associated with trisomy F. Drug therapy does not appear to be responsible for the chromosome abnormalities in this patient. A recurrence treated with cortisone and antileukemic agents was followed by a two month remission after which the patient died.

- 3316 BASIS FOR THE SERINE REQUIREMENT IN LEUKEMIC AND NORMAL HUMAN LEUKOCYTES: REDUCED LEVELS OF THE ENZYMES IN THE PHOSPHORYLATED PATHWAY. (E.) Pizer, L. I. (U. Pennsylvania Sch. Med., Philadelphia) and J. D. Regan. *J Nat Cancer Inst* 48(6):1897-1900, 1972.

Enzymes of the "phosphorylated pathway" for serine biosynthesis were assayed by spectrometry or by conversion of isotopically labeled precursors in extracts of normal leukocytes and extracts of leukocytes from patients with acute or chronic granulocytic leukemia. Activity of all enzymes assayed was lower in the leukocyte (both normal and leukemic) preparations than in comparable preparations of cultured human diploid fibroblasts and HeLa or KB cells. Mixing of extracts demonstrated that the low activity in the leukemic cells was not due to the presence of diffusible inhibitors. The greatest difference between leukocytes and other cell types was in the specific activity of glycerate 3-phosphate dehydrogenase, indicating that this enzyme might limit serine synthesis and give rise to the serine requirement exhibited by blood cells.

- 3317 CYTOGENETIC STUDIES IN MALIGNANT LYMPHOMAS: A STUDY OF 28 CASES. (E.) Coutinho, V. (Fac. Med., Sao Paulo, Brazil), C. Bottura and R. P. Falcao. *Brit J Cancer* 24(4):789-801, 1971.

Chromosome studies were carried out, by a direct method, in 28 subjects with malignant lymphomas. All patients were untreated at the time of the study,

except for one with Hodgkin's disease. Lymph node cells were analyzed in 24 of the cases, ascitic fluid sediments in three, and bone marrow cells in one. Chromosome abnormalities, both numerical and structural, were found in 12 of 14 cases of well-differentiated and poorly differentiated lymphocytic lymphomas and reticulum cell sarcomas, and in eight of 14 cases of Hodgkin's disease. The karyotypes were different from case to case and there was no correlation with the histology of the tumors. In individual cases, the abnormalities followed a clonal pattern indicating a common precursor for the abnormal cells. The modal number of chromosomes was near-diploid in the lymphocytic lymphomas and reticulum cell sarcomas, except for one case which was hypertetraploid. Hodgkin's disease showed two main features; a predominant population of cells with normal karyotype which were thought to be normal mitotic lymphocytes, and a small number of cells with a predominantly hypertriploid number of chromosomes. These latter cells were considered to be the neoplastic reticulum cell component of the disease.

- 3318 ULTRASTRUCTURE AND ENZYME ULTRACYTOCHEMISTRY OF HUMAN RENAL CELL CARCINOMA. (E.)

Yokoyama, M. (M. D. Anderson Hosp. Tumor Inst., Houston, Texas). *Cancer Bull* 23(5):91-92, 100, 1971.

The exact subcellular localization of various phosphatases was determined by ultracytochemical methods in renal cell carcinomas from five men and five women. Normal Chinese hamster, rat and human renal tissue was studied as a control. Carcinoma cells had pleomorphic nuclei with prominent nucleoli, large lipid droplets, and abundant cytoplasmic glycogen particles and organelles. Frequently, tumor cells were connected to one another and circumscribed by a basement membrane forming relatively differentiated tubular structures. In enzyme ultracytochemistry of the tumors, seven out of nine showed alkaline phosphatase activity located at microvilli on the luminal surface, as well as at the lateral cell surface in tumor cells forming tubules. Acid phosphatase (ACPase) activity was detected in all nine tumors studied and was localized mainly in lysosomes and the Golgi apparatus of both tumor and proximal tubular cells. The Golgi apparatus of tumor and proximal cells also contained thiamine pyrophosphatase (TPPase) and inosine diphosphatase (IDPase). Although IDPase was also seen in the endoplasmic reticulum of proximal cells, it was absent from that of tumor cells. Two of the four cases studied showed glucose-6-phosphatase (G6Pase) activity located mainly in the endoplasmic reticulum and nuclear envelope of tumor cells and proximal tubule cells. TPPase, IDPase and G6Pase activity was also detected on microvilli and lateral plasma membrane of tumor cells arranged in tubular formation. The similarities between tumor and normal renal cell enzyme patterns suggest that the renal cell carcinomas arose from proximal convoluted tubules. Presence of various enzyme activities at the lateral cell surface of the renal carcinoma cells suggests that functional dedifferentiation of the plasma membrane actually takes place in the tumor.

AGE AT MENARCHE AND BREAST CANCER. (E.) Staszewski, J. (Inst. Oncol., Gliwice, Poland). *J Nat Cancer Inst* 47(5):935-940, 1971.

Results of a case-control study in the Katowice pole Districts of Poland are presented. The distribution of females with "late" menarche (age ≥ 16), both cases and controls, was similar to the distribution reported for Tokyo and much higher than in Los Angeles or Boston, where breast cancer incidence is also low. Females reporting menarche at ages < 16 years had breast cancer risks 1.76 as high as those reporting "late" menarche. This differential in risk was more marked for women up to 44 years of age than for older women. Other sources indicate an increase in breast cancer risk in Poland and also a decrease in the proportion of late menarche. A relationship between geographic and secular variation in breast cancer occurrence and in menarche pattern is suggested. Age at menarche and breast cancer risk are probably indirectly associated, with nutrition being the possible common factor.

α -FETOPROTEIN IN RATS TRANSPLANTED WITH ASCITES HEPATOMA. (E.) Watabe, H. (Hokkai-Sch. Med., Japan), H. Hirai and H. Satoh. *Cancer* 33(2):189-199, 1972.

Change in the concentration of embryo-specific α -globulin (α -fetoprotein) was studied by immunoelectrophoresis and immunodiffusion in the serum of strain rats, in the serum of gestating female rats and in the serum and ascitic fluid of rats bearing transplantable ascites hepatomas. Serum α -fetoprotein concentration in fetuses decreased two weeks after birth to approximately one-half prenatal level and disappeared in five weeks. α -Fetoprotein was also present in serum of gestating rats in low concentrations which disappeared one week after delivery. α -Fetoprotein was also present in the serum and/or ascitic fluid of rats bearing transplantable ascites tumors. Twenty-six ascites hepatoma lines tested produced α -fetoprotein. One of five lines of Morris hepatoma produced α -fetoprotein as did four of seven sarcoma sublines. α -Fetoprotein was also present in extracts of α -fetoprotein-producing tumor

3405 A NEW METHOD FOR PULMONARY CYTOLOGY IN RATS AND HAMSTERS. (E.) Schreiber, H. (Oak Ridge Natl. Lab., Tenn.) and P. Nettesheim. *Cancer Res* 32(4):737-745, 1972.

3406 THE USE OF OLIGODEOXYRIBONUCLEOTIDES ISOLATED FROM PULSE-LABELED HeLa IN DNA SYNTHESIS IN VITRO. (E.) Schandl, E. K. (Dept. Biol., U. Laval, Quebec, Canada). *Cancer Res* 32(4):726-730, 1972.

3407 BIOLOGY AND KARYOLOGY OF MURINE LEUKEMIA L1210 XENOGRAFTED TO THE HAMSTER. (E.) Goldenberg, D. M. (Temple U. Sch. Med., Philadelphia, Pa.). *Cancer Res* 32(4):813-824, 1972.

3408 VALUE OF SERUM COPPER MEASUREMENT IN LYMPHOMAS AND SEVERAL OTHER MALIGNANCIES. (E.) Mortazavi, S. H. (Inst. Nuclear Med. Pahlavi U. Med. Sch., Shiraz, Iran), A. Bani-Hashemi, M. Mozafari and A. Raffi. *Cancer* 29(5):1193-1198, 1972.

3409 TUMORS OF CERUMINOUS GLANDS. (E.) Wetli, C. V. (Jackson Memorial Hosp., Miami, Florida), V. Pardo, M. Millard and K. Gerston. *Cancer* 29(5):1169-1178, 1972.

3410 ADENOID CYSTIC CARCINOMA OF THE HEAD AND NECK. (E.) Eby, L. S. (Good Samaritan Hosp. Med. Ctr., Portland, Ore.), D. S. Johnson and H. W. Baker. *Cancer* 29(5):1160-1168, 1972.

3411 CANCER OF THE GASTRIC STUMP AFTER PARTIAL GASTRECTOMY (BILLROTH II PRINCIPLE) FOR ULCER. (E.) Saegesser, F. (U. Lausanne Med. Sch., Switzerland) and D. Jämes. *Cancer* 29(5):1150-1160, 1972.

3412 ADENOACANTHOMA (ADENOSQUAMOUS CARCINOMA) OF THE PANCREAS. (E.) Cihak, R. W. (Dept.

Path., Atomic Bomb Casualty Commission, Hiroshima, Japan), T. Kawashima and A. Steer. *Cancer* 29(5): 1133-1140, 1972.

3413 ULTRASTRUCTURE OF PERIANAL PAGET'S DISEASE. (E.) Ferenczy, A. (Coll. Physicians Surg., Columbia U., New York, N.Y.) and R. M. Richart. *Cancer* 29(5):1141-1149, 1972.

3414 TESTICULAR CARCINOMA FOLLOWING ORCHIDOPEXY. (Fr.) Rioult, J. (CHU, Rennes, France), G. Colin and J. Bauchart. *Ann Urol* 5(3):193-196, 1971.

3415 BSP HALF-TIME IN PATIENTS WITH NON-ADVANCED CERVICAL CANCER. (Pol.) Slomska, J. (Inst. Oncol., Gliwice, Poland) and Z. Wozniakowska. *Wiad Lek* 24(20):1897-1900, 1971.

3416 SUPRAFOCAL DISORDERS OF SUPERFICIAL SENSITIVITY IN EXTRAMEDULLAR TUMOURS AND THEIR POSSIBLE CAUSES. (Rus.) Orlov, Yu. A. (Sci. Res. Inst. Neurosurg. Kiev, USSR). *Vrach Delo* (8):101-104, 1971.

3417 MALIGNANT TUMOURS AND CHROMOSOMAL ABBERATIONS. (Hun.) Schuler, D. (Semmelweis Med. Sci. U., Budapest, Hungary) and M. Dobos. *Magyar Onkologia* 15(3):121-127, 1971.

3418 STUDY OF THE LEUKOCYTES OF PATIENTS WITH CHRONIC MYELOLEUCOSIS. (Rus.) Morosova, V. T. (Ctr. Inst. Postgrad. Med., Moscow, USSR), N. G. Shevchenko, G. V. Vereshchagina, N. F. Trusova, T. A. Bektermirov and Yu. B. Fedorova. *Lab Delo* 8: 462-466, 1971.

3419 METASTATIC NEUROBLASTOMA OF THE MANDIBLE: REVIEW OF LITERATURE AND REPORT OF CASE. (E.) Angelopoulos, A. P. (Div. Oral Path., Dalhousie U., Halifax, Nova Scotia, Canada), H. B. Tilson and F. W. Stewart. *J Oral Surg* 30(2):93-105, 1972.

3420 PROLIFERATION CONTROL OF CULTIVATED HUMAN GLIA-LIKE CELLS UNDER "STEADY STATE" CONDITIONS. (E.) Westermarck, B. (Wallenberg Lab., U. Uppsala, Sweden). *Exp Cell Res* 69:259-264, 1971.

3421 CERVICAL LYMPH NODE METASTASES FROM UPPER RESPIRATORY OR DIGESTIVE TRACT CARCINOMAS. (Fr.) Cachin, Y. (Gustave-Roussy Inst., Villejuif, France), S. Hamel, R. Gerard-Marchant, H. Sancho, C. Micheau and J.-L. Caen. *Ann Otolaryng* 88(10-11): 547-554, 1971.

3422 LYMPHANGIOSARCOMA ARISING IN CHRONIC CONGENITAL AND IDIOPATHIC LYMPHOEDEMA. (E.) Mackenzie, D. H. (Westminster Med. Sch., London, England). *J Clin Path* 24(6):524-529, 1971.

3423 NET MOVEMENTS OF MONOVALENT AND BIVALENT CATIONS, AND THEIR RELATION TO ENERGY METABOLISM, IN SLICES OF HEPATOMA 3924A AND OF A MAMMARY TUMOUR. (E.) Van Rossum, G. D. V. (Johnson Res. Fdn., U. Pennsylvania, Philadelphia), M. Gosalvez T. Galeotti and H. P. Morris. *Biochim Biophys Acta* 245(2):263-276, 1971.

3424 GLYCOSPHINGOLIPIDS AND AMINES IN NEOPLASTIC MAST CELLS. (E.) Masek, K. (U. Connecticut Sch. Med., Hartford), K. Bensch and H. W. Felsenfeld. *Biochem Pharmacol* 20(9):2309-2318, 1971.

3425 LACTATE DEHYDROGENASE ISOENZYMES IN TUMOURS OF THE NERVOUS SYSTEM. (E.) Timperley, W. R. (Dept. Neuropath. U. Manchester, England). *Acta Neuropath* 19(1):20-24, 1971.

3426 HISTOAUTHORADIOGRAPHIC EXAMINATIONS OF HUMAN GASTRIC MUCOSA IN CHRONIC GASTRITIS AND GASTRIC CANCER. (Ger.) Steenbeck, L. (German Acad. Sci., Berlin) and G. Wolff. *Arch Geschwulstforsch* 38(2):132-138, 1971.

3427 INFLUENCE OF HEPARIN, PLASMIN, TRYPSIN, PROTAMINE AND EPSILON-AMINO-CAPROIC ACID ON STICKINESS AND AGGREGATION OF ASCITES CELLS *IN VITRO*. (Ger.) Hilgard, P. (Sec. Intern. Med., U. Ulm, Germany). *Arch Geschwulstforsch* 38(1):27-33, 1971.

3428 CELL DIVISION AND ENERGY DEPENDENT METABOLIC POWER OF EHRICH-ASCITES-TUMOR CELLS UNDER AEROBIC AND ANAEROBIC CONDITIONS. (Ger.) Krause, H. P. (Physiol. Chem. Inst., U. Tübingen, Germany), H. Probst and F. Schneider. *Z Naturforsch* 266(8):780-787, 1971.

3429 LIPID AND FATTY ACID COMPOSITIONS OF BRAIN TUMOR. (Jap.) Onodera, Y. (Tokyo Med. Coll., Japan), M. Hasue, Y. Yamamoto and T. Miwa. *Brain Nerve* 23(7):785-792, 1971.

3430 HISTOCHEMICAL STUDIES ON ACTIVITY OF PHOSPHORYLASE OF GASTRIC CANCER CELLS IN THE RESECTED STOMACH. (Jap.) Kuwano, A. (Kumamoto U. Med. Sch., Japan). *J Kumamoto Med Soc* 45(2):145-168, 1971.

3431 RENAL METABOLISMS OF EHRICH ASCITES TUMOR-BEARING MICE. (Jap.) Niimura,

ch. Med., Keio U., Japan), Y. Naide and T. Sakur-
J Keio Med Soc 48(5):401-412, 1971.

THE EFFECT OF REVERSAL OF Na⁺ AND K⁺
 ELECTROCHEMICAL POTENTIAL GRADIENTS ON
 ACTIVE TRANSPORT OF AMINO ACIDS IN EHRICH
 TUMOR CELLS. (E.) Schafer, J. A. (U.
 na Med. Ctr., Birmingham) and E. Heinz.
Am Biophys Acta 249(1):15-33, 1971.

FURTHER STUDIES ON AN ESTERASE INHIBITOR
 IN HUMAN LEUKOCYTE CYTOSOL. (E.) Janoff,
 ate U. New York, Stony Brook) and J. Blondin.
vest 25(6):565-571, 1971.

CONTROL OF DNA REPLICATION IN *PHYSARUM*
POLYCEPHALUM: I. SPECIFIC ACTIVITY OF
 PHOSPHORYLASE IN ISOLATED NUCLEI DURING THE
 CYCLE. (E.) Solao, P. B. (Biochem. Lab., U.
 , Brighton, England) and S. Shall. *Exp Cell*
 :295-300, 1971.

ENDOCYTOSIS AND LYSOSOME FORMATION IN BLOOD
 LYMPHOCYTES TRANSFORMED BY PHYTOHEMAGGLUTININ.
 Biberfeld, P. (Karolinska Inst. Med. Sch., Stock-
 Sweden). *J Ultrastruct Res* 37(1-2):41-68, 1971.

METASTASIS OF MAMMARY CARCINOMA IN A CHRO-
 MOPHOBE ADENOMA OF THE HYPOPHYSIS. (E.)
 Zwan, A. (U. Med Ctr., Leyden, Netherlands),
 endijk and G. T. A. M. Bots. *Psychiat Neurol*
er 74(5):369-377, 1971.

TRANSMURAL POTENTIAL DIFFERENCE (PD) IN
 THE BODY OF THE ESOPHAGUS IN PATIENTS WITH
 ITIS, BARRETT'S EPITHELIUM AND CARCINOMA OF
 PHAGUS. (E.) Vidins, E. I. (Queen's U.,
 n, Ontario, Canada), J. A. E. Fox and I. T.
Amer J Dig Dis 16(11):991-999, 1971.

THE INFLUENCE OF YOSHIDA SARCOMA, ε-
 AMINOCAPROIC ACID AND SINTROM ON THE BLOOD
 G SYSTEM IN RATS. (E.) Kotschy, M. (Med
 roclaw, Poland), M. Grzebieluch, J. Szacki,
 Lawinski. *Arch Immun Ther Exp* 19(4):515-522,

THE INFLUENCE OF PROLONGED ADMINISTRATION
 OF ε-AMINOCAPROIC ACID AND SINTROM ON ME-
 S OF YOSHIDA SARCOMA TO THE LUNGS IN RATS.
 awinski, M. (Med. Sch., Wroclaw, Poland),
 ki, M. Grzebieluch and M. Kotschy. *Arch*
ner Exp 19(4):523-532, 1971.

SERUM L-ASPARAGINASE IN TUMOR RATS AND
 PATIENTS OF MALIGNANT TUMOR. (Jap.)

Nakanishi, K. (Tokyo Med. Coll., Japan), Y. Kawamura
 and M. Takenoshita. *J Tokyo Med Coll* 28(1):80-84,
 1970.

3441 CRITICAL CYTOPLASMIC MASS AND THE INITIATION
 OF THE PROLIFERATIVE RESPONSE IN THE RAT
 LIVER. (E.) Weinbren, K. (U. Nottingham Med.
 Sch., England), G. A. Stirling, S. L. A. Washington,
 S. B. Hooper and J. Laughlin. *Br J Exp Path*
 52(5):583-588, 1971.

3442 ULTRASTRUCTURE OF FUNCTIONING BETA CELL
 TUMORS OF THE PANCREATIC ISLETS. (E.)
 Suzuki, H. (Aichi Cancer Ctr. Res. Inst., Nagoya,
 Japan) and M. Matsuyama. *Cancer* 28(5):1302-1313,
 1971.

3443 INTRACELLULAR DISTRIBUTION OF LACTATE DE-
 HYDROGENASE ISOENZYMES IN BRAIN TUMOURS. (E.)
 Nagy, A. (Inst. Neurosurg., Budapest, Hungary), E.
 Rona, F. Katona and M. Wollemann. *Enzyme* 12(4):
 467-472, 1971.

3444 MACROMOLECULAR VIROSTATIC SUBSTANCES AND
 THEIR INTERFERON INDUCING ACTIVITY. (Ger.)
 Schramm-Thiel, N. (Inst. Therap. Biochem., U. Frankfurt,
 Germany), R. Freiskorn, M. Kettner, G. May and A. Wacker.
Arzneimittelforschung 21(9):1389-1392, 1971.

3445 INTRACARDIAC MYXOMA IN SIBLINGS. (E.)
 Krause, S. (Montefiore Hosp. Pittsburgh,
 Pa.), L. N. Adler, P. S. Reddy and G. J. Magovern.
Chest 60(4):404-406, 1971.

3446 THE DILEMMA OF COINCIDENT ACTIVE PULMONARY
 TUBERCULOSIS AND CARCINOMA OF THE LUNG.
 (E.) Tunell, W. P. (George Washington U. Sch.
 Med., Washington, D.C.), Y.-C. Koh and P. C. Adkins.
J Thorac Cardiovasc Surg 62(4):563-567, 1971.

3447 PHOSPHORUS INCORPORATION IN THE EHRICH
 ASCITES TUMOR CELL. (E.) Levinson, C.
 (U. Texas Med. Sch., San Antonio) and E. D. Gordon,
 Jr. *J Cell Physiol* 78(2):257-264, 1971.

3448 LEUKAEMIC SUBCLONES IN CHRONIC MYELOGENOUS
 LEUKAEMIA: DIFFERENCES IN DRUG SENSITIVITY
 AND IN DIFFERENTIATION CAPACITY. (E.) Pedersen, B.
 (U. Hosp. Copenhagen, Denmark) and S.-A. Killmann.
Acta Med Scand 190(1-2):61-69, 1971.

3449 THE ACUTE LEUKEMIC CELL: IV. DNA SYNTHESIS
 IN PERIPHERAL BLOOD AND BONE MARROW.
 (E.) Schumacher, H. R. (Harrisburg Hosp., Pa.),
 A. E. McFeely, K. D. Davis and T. K. Mangel.
Amer J Clin Path 56(4):508-514, 1971.

3450 STUDIES ON PLASMA MEMBRANES: XV. A SEX
 DIFFERENCE IN ALKALINE PHOSPHATASE ACTIVI-

- TIES OF PLASMA MEMBRANES ISOLATED FROM RAT LIVER. (E.) Emmelot, P. (Netherlands Cancer Inst., Amsterdam) and C. J. Bos. *Biochim Biophys Acta* 249(1):293-300, 1971.
- 3451 THE EFFECT OF 'AGING' OF AN INHIBITOR OF SPONTANEOUS TUMORS IN MICE: II. OBSERVATIONS AT AGING FROM 101-1346 DAYS. (E.) Strong, L. C. (Leonell C. Strong Res. Fdn., San Diego, Calif.) and H. Matsunaga. *J Surg Oncology* 3(4):369-378, 1971.
- 3452 THE FIBRINOLYTIC ENZYME SYSTEM IN HEPATIC CIRRHOSIS AND MALIGNANT METASTASES. (E.) Ogston, D. (Dept. Med., U. Aberdeen, Scotland), N. B. Bennett and C. M. Ogston. *J Clin Path* 24(9):822-826, 1971.
- 3453 HISTOMETRICAL GLOMERULAR STUDIES ON THE KIDNEYS IN MULTIPLE MYELOMA AND IN ACUTE MEMBRANOUS GLOMERULONEPHRITIS (LIPOID NEPHROSIS). (E.) Wehner, H. (Inst. Path. U. Tübingen, Germany), F. Feurer and I. Wehner. *Path Europ* 6(4):422-432, 1971.
- 3454 DIFFERENTIATED NEPHROBLASTOMA: SOLID, CYSTIC OR MIXED. (E.) Fowler, M. (Adelaide Children's Hosp., South Australia). *J Path* 105(3):215-218, 1971.
- 3455 PATHOLOGICAL STUDIES ON CARCINOMA OF THE GALLBLADDER: ESPECIALLY ON THE RELATIONSHIP BETWEEN DEEP CHOLECYSTIC FOSSA AND OCCURRENCE OF CARCINOMA. (E.) Kojima, K. (Ctr. Path., Welfare Federation, Nagaoka, Japan) and K. Saito. *Acta Med Biol* 19(2):151-163, 1971.
- 3456 ACUTE PROMYELOCYTIC LEUKEMIA WITH FIBRINOGEN AND FACTOR XIII DEFICIENCIES. (E.) Karaca, M. (Internal Clin. Ege U., Izmir, Turkey), N. Tartaroglu, C. Yavuzgil, T. Kabakci and A. Kocabas. *New Istanbul Contrib Clin Sci* 10(1):1-8, 1971.
- 3457 ULTRASTRUCTURE OF HUMAN AND EXPERIMENTAL EPENDYMOMAS: A COMPARATIVE STUDY. (E.) Goebel, H. H. (New York U. Med. Ctr., New York) and H. Cravioto. *J Neuropath* 31(1):54-71, 1972.
- 3458 INDUCED CHANGES IN THE RATES OF URIDINE-³H UPTAKE AND INCORPORATION DURING THE G₁ AND S PERIODS OF SYNCHRONIZED CHINESE HAMSTER CELLS. (E.) Stambrook, P. J. (U. Kentucky Med. Ctr., Lexington) and J. E. Siskin. *J Cell Biol* 52:514-525, 1972.
- 3459 THE EFFECT OF UREMIA ON PROLIFERATION KINETICS OF BASAL CELLS OF SKIN. (Ger.) Gastrup, H. J. (Path. Inst., U. Koln, Germany) and K. J. Lennartz. *Beitr Path Bd* 145(2):204-206, 1972.
- 3460 THE EFFECT OF ASCITES FLUID OF RAT ASCITES HEPATOMA ON DRUG METABOLIZING ENZYMES OF RAT LIVER MICROSOMES. (E.) Yoshida, H. (Kumamoto U. Med. Sch., Japan). *Kumamoto Med J* 24(2):55-67, 1971.
- 3461 PATHOLOGY OF COMMON SKIN TUMORS. (E.) Lever, W. F. (Tufts U. Sch. Med., Boston, Mass.). *J Surg Oncology* 3(3):235-250, 1971.
- 3462 ENZYME HISTOCHEMISTRY OF EXPERIMENTAL EMBRYO-DERIVED TERATOCARCINOMAS. (E.) Damjanov, I. (Dept. Path., U. Zagreb, Yugoslavia), D. Solter and N. Skreb. *Z Krebsforsch* 76(4):249-256, 1971.
- 3463 SYNGENETIC TRANSPLANTATION OF SKIN AT EARLY STAGES OF EXPERIMENTAL HEPATOCARCINOGENESIS. (Rus.) Korosteleva, T. A. (N. N. Petrov Res. Inst. Oncology, USSR Ministry Public Hlth., Leningrad), L. S. Potapenkova and A. S. Belokhvostov. *Vop Onkol* 17(11):55-58, 1971.
- 3464 BLOOD FLOW IN IRRADIATED MOUSE SARCOMA AS DETERMINED BY THE CLEARANCE OF XENON-133. (E.) Kallman, R. F. (Stanford U. Sch. Med., Calif.), G. L. DeNardo and M. J. Stasch. *Cancer Res* 32(3):483-490, 1972.
- 3465 EFFECT OF DL-GLYCERALDEHYDE ON MOUSE NEUROBLASTOMA CELLS IN CULTURE. (E.) Sakamoto, A. (American Med. Ctr., Denver, Colo.) and K. N. Prasad. *Cancer Res* 32(3):532-534, 1972.
- 3466 SURVIVAL OF HEMATOPOIETIC AND LYMPHOMA COLONY-FORMING CELLS *IN VIVO* FOLLOWING THE ADMINISTRATION OF A VARIETY OF ALKYLATING AGENTS. (E.) Valeriote, F. A. (Washington U. Sch. Med., St. Louis, Mo.) and S. J. Tolen. *Cancer Res* 32(3):470-476, 1972.
- 3467 MALIGNANT MIXED MÜLLERIAN TUMORS OF THE UTERUS. (E.) Williamson, E. O. (U. Louisville Sch. Med., Ky.) and W. M. Christopherson. *Cancer* 29(3):585-592, 1972.
- 3468 ULTRASTRUCTURE OF THE GRANULAR CELL MYOBLASTOMA: SO-CALLED ABRIKOSSOFF'S TUMOR. (E.) Caputo, R. (Derm. Clin., U. Milan, Italy), A. G. Bellone and R. Tagliavini. *Arch Derm Forsch* 242:127-136, 1972.
- 3469 FLOURESCENT BANDING PATTERNS OF RAT CHROMOSOMES IN NORMAL CELLS AND PRIMARY HEPATOCELLULAR CARCINOMAS. (E.) Wolman, S. R. (New York U. Sch. Med., N.Y.), T. F. Phillips and F. F. Becker. *Science* 175(4027):1267-1269, 1972.

PRIMARY MULTIPLE CANCER IN GYNECOLOGY. (Sp.)
Pepe, Fr. (No affiliation), J. J. Pedrazzi,
orenstein and C. Sforza. *Rev Soc Obst Ginec*
97):224-229, 1971.

THE SPECIFICITY OF AN INCREASE OF ALBUMIN
FRACTION ARGININE IN NEOPLASTIC DISEASES.
Farbiszewski, R. (Dept. Physiological Chem.,
Sch., Bialystok, Poland), K. Worowski and W.
zycki. *Bull Acad Pol Sci (Biol)* 19(7-8):543-
1971.

SOME BIOCHEMICAL CHANGES IN TOTAL AND
SUBCELLULAR FRACTIONS OF THE CARCINOMA-
THYROID TISSUES. (E.) Constantinescu, A.
t. Endocrinology Acad. Med. Sci., Bucharest,
nia), I. Negoescu, M. Don and C. Heltianu.
Roum Endocrinol 8(4):327-334, 1971.

QUINACRINE FLUORESCENT KARYOTYPES OF HUMAN
DIPLOID AND HETEROPOID CELL LINES. (E.)
er, O. J. (Coll. Physicians Surg. Columbia U.,
York, N.Y.), D. A. Miller, P. W. Allderdice,
Dev and M. S. Grewal. *Cytogenetics* 10(5):338-
1971.

BIOCHEMICAL CHARACTERIZATION OF MOUSE &
HUMAN MALIGNANT CELLS *IN VITRO*. (E.)
eri, V. R. (Cancer Res. Inst., Bombay, India),
Revankar, B. N. Mashelkar and K. J. Ranadive.
J Biochem Biophys 8(3):179-182, 1971.

STUDIES ON TUMOR VARIABILITY: I. OBSERVA-
TIONS ON H₁₀Z TUMOR SHORT TERM TISSUE CUL-
tures. (E.) Fadei, L. (Oncological Inst., Bucharest,
ia). *Z Krebsforsch* 77:91-97, 1972.

LIPOFUSCIN IN MALIGNANT AND NON-MALIGNANT
HUMAN PROSTATIC TISSUE. (E.) Muntzing,
Dept. Urology, U. Lund, Sweden) and T. Nilsson.
Krebsforsch 77:166-170, 1972.

CLEAR-CELL ADENOCARCINOMA ("MESONEPHROMA")
OF THE VAGINA: THREE CASES ASSOCIATED WITH
LOCAL SYNTHETIC NONSTEROID ESTROGEN THERAPY. (E.)
da, Y. (Roswell Park Memorial Inst., Buffalo,
, W. J. Hewett, J. J. Barlow and J. W. Pickren.
Cancer 29(5):1208-1214, 1972.

NEUTRAL PROTEASES CONFINED TO ONE CLASS
OF LYSOSOMES OF HUMAN POLYMORPHONUCLEAR
CYTES. (E.) Folds, J. D. (Sch. Med., U.
Carolina, Chapel Hill), I. R. H. Welsh and J.
nitznagel. *Proc Soc Exp Biol Med* 139(2):461-463,
1972.

CLINICOMORPHOLOGICAL ANALYSIS OF CLINICAL
BEHAVIOUR AND PROGNOSIS OF DIFFERENT

ANATOMICAL TYPES OF GASTRIC CARCINOMA. (E.)
Smirnov, N. M. (Prof. Petrov Res. Inst. Oncology,
Leningrad, USSR) and D. P. Berezkin. *Neoplasma* 19(1):
67-74, 1972.

3480 ISOLATION OF ACTIVE RIBOSOMAL SUBUNITS FROM
L5178Y MOUSE LYMPHOMA CELLS. (E.) Faber,
A. J. (U. Alberta Cancer Res. Unit, Canada) and T.
Tamaoki. *Arch Biochem* 149(1):289-294, 1972.

3481 DNA AND ACRIDINE ORANGE INTERACTIONS STUDIED
BY MEANS OF FLUORESCENCE. (Fr.) Fredericq,
E. (U. Liege, Belgium). *Arch Int Physiol Biochim*
74(4):832-833, 1971.

3482 ATYPICAL PHEOCHROMOCYTOMA. (Rus.)
Drampyan, F. S. (Erevan Med. Inst.,
USSR), E. G. Grigoryan and A. G. Partevyan. *Vrach*
Delo 8:108-109, 1971.

3483 CYTOLOGICAL AND CYTOCHEMICAL STUDIES OF
CANCER OF THE ORAL MUCOSA AND OF VINCENT'S
ULCEROUS NECROTIC GINGIVITIS AND STOMATITIS. (Rus.)
Popova, Yu. N. (Med. Inst. Stomatol., Moscow, USSR).
Lab Delo 10:584-587, 1971.

3484 MALIGNANT RETICULOENDOTHELIOSIS IN OTORHI-
NOLARYNGOLOGY: WITH REFERENCE TO TWO
CASES OF TEMPORAL BONE GRANULOMA. (Bul.) Boshkov,
A. N. (No affiliation). *God Zb Med Fak* 17:619-
632, 1971.

3485 CARBOHYDRATE METABOLISM IN LEUKOCYTES FROM
PATIENTS WITH CHRONIC LEUKOSIS. (Rus.)
Vereshchagina, G. V. (Ctr. Inst. Postgrad. Med.
Moscow, USSR). *Lab Delo* 8:466-469, 1971.

3486 ANGIOFIBROMA OF THE PIRIFORM FOSSA. (It.)
Buratti, C. (S. Girardo dei Tintori Hosp.,
Monza, Italy) and F. Migliavacca. *Atti Accad*
Med Lombarda 24(4):440-444, 1969.

3487 STUDIES ON TRITIATED THYMIDINE INCORPORATION
INTO DNA MOLECULES BY ELECTRON MICROSCOPIC
AUTORADIOGRAPHY. (E.) Ogura, H. (Okayama U. Med.
Sch., Japan) and T. Oda. *Acta Med Okayama* 25(1):37-
41, 1971.

3488 THE CONTENT AND DISTRIBUTION OF MUCOPOLY-
SACCHARIDES IN PANCREATIC CANCER. (Rus.)
Perzadaev, R. O. (I. P. Pavlov 1st Med. Inst.,
Leningrad, USSR). *Vop Onkol* 17(11):49-55, 1971.

3489 SKELETAL METASTASES AND MAMMARY CANCER.
(E.) Galasko, C. S. B. (Radcliffe Infirma-
ry, Oxford, England). *Ann Roy Coll Surg Engl* 50:3-
28, 1972.

- 3490 METASTASES TO BONE FROM MALIGNANT MELANOMA. (E.) Steiner, G. M. (Royal Marsden Hosp. Inst. Cancer Res., Sutton, England) and J. S. Macdonald. *Clin Radiol* 23:52-57, 1972.
- 3491 IMPAIRED SYNTHESIS OF LIVER CATALASE IN TUMOR-BEARING RATS. (E.) Kashiwagi, K. (Showa U., Cancer Inst., Tokyo, Japan), T. Tobe, T. Higashi and K. Warabioka. *Gann* 63(1):57-62, 1972.
- 3492 THE REGIONAL LYMPH NODE IN MICE BEARING TRANSPLANTED SYNGENEIC LYMPHOMA CELLS. (E.) Drewinko, B. (Dept. Clin. Path., U. Texas, Houston), M. Jurin and A. E. Howes. *Proc Soc Exp Biol Med* 140(1):339-341, 1972.
- 3493 LYSOSOMAL ENZYME CYTOCHEMISTRY IN ACUTE LEUKAEMIA. (E.) Mann, J. R. (Children's Hosp., Birmingham, England), J. S. Simpson, R. M. Munkley and J. Stuart. *J Clin Path* 24(9):831-836, 1971.
- 3494 DISTRIBUTION OF DNA REPLICATOR SITES IN MAMMALIAN NUCLEI: II. EFFECTS OF PROLONGED INHIBITION OF DNA SYNTHESIS. (E.) Ockey, C. H. (Paterson Lab., Manchester, England). *Exp Cell Res* 70(1):203-213, 1972.
- 3495 TRANSLATION OF TWO MESSENGER RNAs FROM LENS IN A CELL FREE SYSTEM FROM KREBS II ASCITES CELLS. (E.) Mathews, M. B. (MRC Lab. Molecular Biol., Cambridge, England), M. Osborn, A. J. M. Berns and H. Bloemendal. *Nature New Biol* 236(61):5-7, 1972.
- 3496 THE HISTOLOGICAL FINDINGS AFTER INTRA-ARTERIAL CYTOSTATIC PERFUSION OF ORO-FACIAL TUMOURS. (E.) Hornova, J. (J. E. Purkyne U., Brno, Czechoslovakia) and J. Bilder. *Scripta Med* 44(6):305-311, 1971.

Inst. Acad. Med. Lodz, Poland), I. Judkiewicz, E. Polkowska-Kulesza, H. Krauze-Jaworska and J. W. Kozlowski. *Pol Tyg Lek* 27(9):336-339, 1972.

3588 BEHAVIOUR *IN VITRO* OF NERVOUS AND TUMOR TISSUES CULTIVATED TOGETHER. (Ger.) Wolf, M. (Med. Enzyme Res. Assoc. Grünwald/Munich, Germany), M. H. Benitez and K. Ransberger. *Arch Geschwulstforsch* 38(3-4):232-249, 1971.

3589 TUMOR GROWTH AND LIVER REGENERATION: INVESTIGATIONS OF RATS, BEARING WALKER CARCINOSARCOMA 256. (Ger.) Wayss, K. (German Cancer Res. Ctr., Heidelberg, Germany), N. Ertl and M. Volm. *Arch Geschwulstforsch* 38(3-4):250-256, 1971.

3590 DIURNAL RHYTHM OF THE ADRENAL CORTEX FUNCTION IN CHILDREN WITH ACUTE LEUKEMIA. (Rus.) Kalashnikova, G. V. (H. I. Pirogov Med. Inst. Moscow, USSR). *Pediatrics* (12):43-45, 1971.

3591 DISTRIBUTION OF SUCCINATE-DEHYDROGENASE IN TUMOURS OF THE ASTROCYTE SERIES. (Rus.) Savich, K. V. (N. N. Burdenko Sci. Res. Inst. Neurosurg., Acad. Med. Sci. Moscow, USSR). *Op Neurokhir* (6):41-45, 1971.

3592 PULMONARY METASTASIS OF PRIMARY LUNG NEOPLASIA. (It.) Dragoni, G. (Natl. Inst. Tumor Res., Milan, Italy) and G. Viganotti. *Radiol Med* 57(2):119-130, 1971.

3593 RESOLUTION OF BETA-GLUCURONIDASE FROM EHRlich ASCITES CARCINOMA CELLS AND MOUSE BRAIN BY ISOELECTROFOCUSING IN POLYACRYLAMIDE. (Ger.) Coutelle, R. (German Acad. Sci., Berlin). *Acta Biol Med Germ* 27(4):681-691, 1971.

3594 BONE METASTASES IN THE COURSE OF UTERINE CERVIX CANCER. (Pol.) Karnicka-Mlodkowska, H. (Gdansk Acad. Med., Poland) and E. Jordan. *Ginek Pol* 63(2):225-230, 1972.

3595 LOCALIZATION OF THE ACTIVITY OF CERTAIN DEHYDROGENASES IN THE TISSUES OF UTERINE ADENOCARCINOMA. (Pol.) Skalba, P. (Silesian Acad. Med., Zabrze, Poland). *Ginek Pol* 63(2):149-155, 1972.

3596 CANCER OF THE GASTRIC STUMP. (Sp.) Parrilla, P. P. (Valencia Med. Inst., Spain), S. M., Lledo, C. C. Carbonell and J. R. del Castillo. *Med Esp* 66(393):297-302, 1971.

3597 THIAMINE CONTENT IN THE TISSUES, ACTIVITY OF TRANSKETOLASE AND DEVELOPMENT OF EXPERIMENTAL TUMORS WITH DIFFERENT THIAMINE ALLOWANCES IN THE ORGANISM. (Rus.) Diyachkova, L. V. (Inst. Nutr. USSR. Acad. Med. Sci. Moscow, USSR), Ye. M. Shamayeva, G. N. Platonova and V. B. Spirchev. *Vop Pitan* 31(2):42-47, 1972.

3598 OBSERVATIONS ON 600 ENDOMETRIAL CANCERS. (Ger.) Grube, F. O. (Erlangen-Nuremberg U., Germany) and E. Strobel. *Arch Gynaek* 211(4):558-575, 1971.

3599 PRIMARY PAPILLOMA OF THE CEREBELLOPONTINE ANGLE WITH METASTASIS TO THE CEREBRAL HEMISPHERE. (Pol.) Jagodzinski, Z. (Acad. Med. Sci. Lodz, Poland), J. Mackiewicz and W. Papierz. *Neurol Neurochir Pol* 6(22):149-152, 1972.

3600 CRANIOPHARYNGIOMA. (E.) Arseni, C. (Clin. Neurosurg., Bucharest, Rumania) and M. Maretsis. *Neurochirurgia (Stuttgart)* 15(1):25-32, 1972.

PREFACE

Carcinogenesis Abstracts is a publication of the National Cancer Institute. The journal serves as a vehicle through which current documentation of carcinogenesis research highlights are compiled, condensed, and disseminated on a regular basis. It represents an integral part of the Institute's program of fostering and supporting coordinated research into cancer etiology. Issues of *Carcinogenesis Abstracts* normally contain three-hundred-fifty abstracts and three-hundred-fifty citations (unaccompanied by corresponding abstracts). Abstracts and citations refer to the current scientific literature that describes the most significant carcinogenesis research carried on at the National Cancer Institute, other governmental agencies, and private institutions. *Carcinogenesis Abstracts* is intended to be a highly useful current awareness tool for scientists engaged in carcinogenesis research or related areas. The great number and diversity of publications relevant to carcinogenesis make imperative the availability of this service to investigators whose work requires that they keep abreast with current developments in the field.

Carcinogenesis Abstracts is normally published monthly. Volume X covers the scientific literature published from July 1971 through Dec 1972. A cumulative subject and author index for Volume X will be published shortly after the final regular issue. This journal is available free of charge to libraries and to individuals who have a professional interest in carcinogenesis. Requests for *Carcinogenesis Abstracts* from qualified individuals should include statements of their relationship to carcinogenesis research. All correspondence should be addressed as follows.

Carcinogenesis Abstracts
Etiology Area
National Cancer Institute

01 CARCINOGENICITY OF AMOSITE ASBESTOS. (E.)
Selikoff, I. J. (Mount Sinai Sch. Med., New York, N.Y.), E. C. Hammond and J. Churg. *Arch Environ Health (Chicago)* 25(3):183-186, 1972.

data exist concerning the comparative neoplastic potential of the several kinds of asbestos in man. determine whether the amosite variety is carcinogenic, the mortality experience of a group of 230 previously employed in an amosite asbestos factory in the U.S. was studied from 1960 through 1971. Total deaths were twice the expected number (5 vs 46.4 expected). Fourteen deaths were due to asbestosis when none was expected. Deaths from lung cancer and mesothelioma were also excessive (lung cancer deaths vs 2.4 expected). Thus, occupational exposure to amosite asbestos may constitute a serious cancer hazard and its continued industrial use warrants rigorous control. (15 references)

2 ADENOVIRUSES IN HUMAN CANCER. (E.)
McAllister, R. M. (U. Southern California Sch. Med., Los Angeles), R. V. Gilden and M. Green. *Cancer* 27(7):831-833, 1972.

capacity of human viruses to induce tumors in rats, mice and rabbits and their ability to transform rodent cells *in vitro* are the bases for suggesting that adenoviruses are possibly oncogenic in man. In the adenovirus/hamster-tumor system, tumor cells contain no infectious virus but induce T antigen and contain virus-specific RNA. Although a number of reports describe the isolation of adenoviruses from human cancer tissues, attempts to detect adenovirus T antigens and virus-specific antigens in tumor cells have been unsuccessful. Furthermore, adenoviruses differing in oncogenic potential do not induce tumors in cynomolgus or rhesus monkeys during a 2-7 yr observation period. The negative results obtained in serological, biochemical and histological tests suggest that adenoviruses are unlikely to be important causes of human cancer. (15 references)

CYTOGENESIS AND DIFFERENTIATION OF PRIMITIVE CENTRAL NEUROEPITHELIAL TUMORS. (E.)
Stein, L. J. (Stanford U. Sch. Med., Calif.). *Neuropath* 31(1):7-26, 1972.

potential or actual differentiating capacities of primitive neoplasms of the central nervous system are reviewed, including medulloepithelioma, cerebral glioblastoma, polar spongioblastoma, ependymoblastoma and pineal parenchymal tumors. Autoradiographic and electron microscopic evidence of morphological, biochemical and divergent differentiation is presented. Capacity of medulloepithelioma, cerebral neuroblastoma and medulloblastoma for stroma induction is also described. The phenomenon of cellular differentiation is discussed in terms of the facultative or potential genome of a cell providing a basis for effective genomes and thus a genetic basis for embryonal competence or capacity, and for patho-

logical metaplasia. The observations reported constitute a body of evidence which will enable improved diagnostic patterns to be used. (107 references)

3604 SELECTIVE REDUCTION OF TUMORIGENICITY OF TOBACCO SMOKE. II. EXPERIMENTAL APPROACHES. (E.) Hoffmann, D. (Amer. Hlth. Fdn., New York, N.Y.) and E. L. Wynder. *J Nat Cancer Inst* 48(6):1855-1868, 1972.

Recent information on the identity of carcinogens in tobacco smoke is reviewed and measures presently under investigation to reduce smoking-related tumorigenesis are described. Three types of tumorigenic agents have been identified in tobacco smoke: tumor initiators, tumor accelerators and tumor promoters. Tumor initiators in tobacco smoke tar include polynuclear aromatic hydrocarbons formed as tobacco burns. Tumor accelerators do not act as whole carcinogens, promoters or tumor initiators. However, they do accelerate the activity of carcinogens and initiators. Tumor accelerators in tobacco smoke include *trans*-4,4'-dichlorostilbene, *N*-alkyl indoles and *N*-alkyl carbazoles. Tumor promoters have been shown to reside in the weakly acidic portion of tobacco tar. *N*-alkyl-aminophenols, volatile phenols and fatty acids are among identified tumor promoters. However, most tumor promoters in tobacco smoke have not been identified. Carcinogens which have been identified in the gaseous phase of tobacco smoke include arsenic, nickel carbonyl, nitro olefins and volatile *N*-nitrosamine. The bladder carcinogens aminofluorene and β -naphthylamine are present in trace amounts in tobacco smoke. However, it is thought that the metabolism of tobacco constituents, including nicotine, rather than bladder carcinogens in smoke, is responsible for the increased incidence of bladder cancer in smokers. Among methods for reducing tumorigenicity of tobacco smoke are decreasing the amount of leaf tobacco in cigarettes while increasing the proportion of stalk and stem tobacco, altering tobacco curing procedures, altering nitrate concentrations of cigarette tobacco and manufacturing cigarettes from reconstituted tobacco sheets rather than from natural tobacco. Experiments on tumorigenicity of tobacco substitutes, including spinach and hay, are also underway. (64 references)

3605 HERPES-LIKE SIMIAN VIRUSES: RETROSPECTIVE AND PROSPECTIVE CONSIDERATIONS. (E.)
Weller, T. H. (Harvard Sch. Public Hlth., Boston, Mass.) and R. P. Strong. *J Nat Cancer Inst* 49(1):209-211, 1972.

Initial studies on poliomyelitis and the development of polio-vaccines established a basic pattern for applied virologic research that included the preferential use of old-world monkeys as experimental subjects. Subsequent work using old-world monkeys led to an accumulation of knowledge regarding simian viruses. To date, 57 serotypes of simian agents representing seven different virus families have been discovered. The use of old-world monkeys, however, introduced new occupational hazards invol-

ving infection by herpes B virus. Some lots of polio vaccine were discovered to be contaminated with SV40. In 1967, seven people died following exposure to a previously unrecognized agent affecting a shipment of African green monkeys. Recently, several genera of new-world monkeys have become available for research purposes and have been rapidly accepted by workers outside the field of classical virology. This has increased the opportunities for contact of humans with new, unknown or poorly-understood simian viruses. *Herpesvirus saimiri*, recovered from the squirrel monkey, can induce highly malignant lymphomas in other new-world primates and in animals as taxonomically distant as rabbits. The cytomegaloviruses, a host-specific group of herpes-type viruses, can produce congenital brain damage and a wide variety of clinical syndromes in man. Thus, until the hazards to man of the new oncogenic herpesviruses are defined, distribution of the new agents and of their natural hosts should be limited to laboratories equipped to handle dangerous viruses. (6 references)

- 3606 IMMUNOLOGY OF MAMMARY GLAND CANCER OF THE MOUSE. (Fr.) Hollmann, K. H. (Broussais Hosp. Paris, France). *Rev Eur Etudes Clin Biol* 16(10):969-980, 1971.

The essential etiologic agent of mouse mammary cancer is mammary tumor virus (MTV), which is usually transmitted through the mother's milk to the nursing young. Tumors then appear at 12-15 months of age and their appearance depend on various factors, especially hormonal ones. The characteristic sudden and simultaneous appearance of several tumors suggests disruption of the equilibrium in the host defense mechanism and points up the importance of immune factors in mouse mammary cancer. The MTV virion, called the "B" particle, is the main antigen for mouse mammary cancer, as has been demonstrated by the immunodiffusion technique *in vitro* and by the homograft rejection test *in vivo*. Actually, several antigens are involved, some derived from the envelope and some from the interior of the virion. Tumor-specific antigens, not associated with the virus, have also recently been demonstrated; they vary from one tumor to another, and are not present in all tumors. The immune response of the host against these viral and tumor-specific antigens depends on the integrity of the host's immune system. Particularly important factors in mouse mammary cancer are the age of the mouse at time of infection and the condition of the thymus. (56 references)

- 3607 BRONCHIOLO-ALVEOLAR CARCINOMA. A REAPPRAISAL AFTER 24 YEARS. (E.) Delarue, N. C. (Toronto General Hosp., Canada), W. Anderson, D. Sanders and J. Starr. *Cancer* 29(1):90-97, 1972.

A five-year follow-up study was made of 74 patients with bronchiolo-alveolar carcinoma treated at

Toronto General Hospital between 1948-1965. The age distribution of the patients was similar to that for lung cancer in general: 10.7% were under 40 yr, 79. between 40-70, and 9.6% over 70. Two-thirds of the cases had a history of heavy smoking. The overall three-year survival rate for the 74 patients was 34%, with 41% of the peripheral lesions surviving this period. Only one of four hilar lesions and only two of ten central scars survived three years; none of the multicentric lesions survived this period. Twenty-five of 49 patients having curative or palliative resections survived three years (52%) and 16 survived five years (34%). None of 25 patients with nonresectable or inoperable disease survived the three-year period. When the resection was a lobectomy, a five-year survival of 52% was achieved. This rate is a clear indication of the potential curability of bronchiolo-alveolar carcinoma that is recognized and treated in its early localized peripheral state. (35 references)

- 3608 ROLE OF IMMUNOLOGIC DISTURBANCE IN HUMAN ONCOGENESIS: SOME FACTS AND FANCIES. (E.) Kaplan, H. S. (Stanford U. Sch. Med., Calif.). *Brit J Cancer* 24(4):620-634, 1971.

Immunologic mechanisms in the genesis of neoplastic processes are reviewed. Recent investigations into the impairment of immunologic surveillance mechanisms permitting the outgrowth of transformed clones confirm the postulated relationship between certain deficiency states in man and the increased incidence of neoplasms. The vital role of the thymus gland in maintaining immunologic competence is discussed on the basis of steroid, antimetabolite and antilymphatic globulin activity. Evidence of the widening spectrum of congenital immunologic deficiency concomitant with oncogenesis is presented. Studies on the impairment of cell-mediated immunity in the early stages of Hodgkin's disease are summarized along with studies of the significance of prior occurrence of infectious mononucleosis in some cases of Hodgkin's disease. There is evidence that lymphoid cells of patients with infectious mononucleosis undergo sustained antigenic alteration. By inducing antigenic alterations in lymphoid cell subpopulations, EB and other noncogenic viruses may initiate sustained autoimmune lymphoproliferative responses leading ultimately to Hodgkin's disease and other forms of lymphoid neoplasia. - 3609 IMMUNOLOGICAL AND RELATED ASPECTS OF NASOPHARYNGEAL CARCINOMA. (E.) Nelson, D. (Dept. Bacteriol., U. Sydney, Australia) and M. Nelson. *Aust Radiol* 15(3):227-232, 1971.

Evidence, mainly sero-epidemiological, was examined for an association between Epstein-Barr virus (E.B.) infection and nasopharyngeal carcinoma (N.P.C.). Recent studies bearing on N.P.C. antigens and the general immunological status of N.P.C. patients were

reviewed. Patients with N.P.C. have much higher levels of antibodies to E.B.V. and its associated antigens than do appropriate controls. Tissue culture studies have also demonstrated an association between a herpes-type virus and N.P.C. Lymphoblastoid cell lines carrying herpes-type virus particles established from biopsies of N.P.C. tumors. Cell lines differ from those derived from Burkitt's lymphoma in that they carry a receptor which complexes of sheep erythrocytes and anti-sheep erythrocyte antibody IgM can become attached. Cell lines from Burkitt's lymphoma carry instead a receptor for complexes of sheep erythrocytes and anti-sheep erythrocyte antibody IgG. Sera from N.P.C. patients reacted with one or more tumor cell constituents--nuclei, membranes and/or cytoplasm. The nuclear and membrane antigens were also found on normal epithelial and lymphoid cells and the cytoplasmic antigen on all normal epithelial cells. Nuclear and membrane antigens could represent, respectively, antigens of a virus and antigens determined by that virus; however, their presence on the epithelial and lymphoid cells must be explained. There is no evidence for an immunological defect playing a part in the development of N.P.C. It is concluded that N.P.C. has a viral etiology; the virus remains to be identified. A genetic susceptibility may explain the racial distribution of N.P.C. (References)

ADENOCARCINOMA OF THE VAGINA IN YOUNG WOMEN. THE STILBESTROL-ADENOSIS-ADENOCARCINOMA OF THE VAGINA SYNDROME. (E.) Fetherston, (St. Mary's Hosp., Milwaukee, Wis.), A. S. and M. E. Speckhard. *Wisconsin Med J* 73:87-93, 1972.

histories of a patient with adenocarcinoma of the vagina and a patient with a benign vaginal adenosis are presented as evidence of a stilbestrol-adenosis-adenocarcinoma syndrome. Both patients had been subject in utero to the influence of stilbestrol administered to their mothers during pregnancy. Adenosis and adenocarcinoma were limited to the upper vagina and may have originated in Muellerian tissue sensitive to estrogen. The possibility of placental stilbestrol transfer with subsequent stimulation of receptor sites of the vaginal anlage during organogenesis is suggested. The stilbestrol may influence the developing Muellerian tissue in such a way that abnormal glandular tissue persists in the upper vagina. Pelvic examinations and close follow-up of asymptomatic young women subject to in utero stilbestrol are recommended. (16 references)

THEORY OF THE ORGANIZATION OF THE MAMMALIAN CELL AND VIRAL DNA GENOMES AND THE MECHANISM OF CARCINOGENESIS. (E.) Becker, Y. Hebrew U.-Hadassah Med. Sch., Jerusalem, Israel). *Israel J Biol Sci* 10(1):47-59, 1972.

ent theory suggests that different families of

DNA molecules are present in the mammalian cell DNA genome and that viral DNA genome resembles, in its organization, cellular DNA. The role of these molecules in the mechanism of carcinogenesis is discussed. The different families of DNA molecules in mammalian cell DNA genome are characterized by the presence or absence of poly-dG-dC or poly-dA-dT sequences; the DNA molecules with poly-dG-dC sequences are transcribed during the S phase of the mammalian cell, while the molecules with poly-dA-dT sequences are transcribed during the G₂ phase along with the DNA that contains information for ribosomal RNA. A prediction of the theory is that transformation of mammalian cells by DNA and RNA tumor viruses, chemical carcinogens and X-irradiation involves the poly-dG-dC sequences in the cellular chromosomal DNA which controls cellular DNA synthesis. Any chemical capable of affecting the poly-dG-dC sequences adjacent to cellular genes controlling DNA synthesis, in a manner that cannot be reversed by the cell, might bring about the transformation of a normal cell into a cancer cell. This possibility might also explain the spontaneous transformation of cells. (53 references)

3612 EVIDENCE FOR AN SV40-RELATED PAPOVAVIRUS INFECTION OF MAN. (E.) Shah, K. V. (Johns Hopkins U. Sch. Hyg. Public Hlth., Baltimore, Md.). *Amer J Epidemiol* 95(3):199-206, 1972.

Evidence of SV40-related papovavirus infections in man is reviewed. The populations studied include subjects exposed to SV40 contaminated poliomyelitis vaccines in the USA and elsewhere, and also inhabitants of northern India where free-living rhesus groups often live close to human communities. Nearly 20% of 12-14 yr old Maryland children who received contaminated polio vaccine had SV40 antibodies in their sera. Antibodies were also found in some elderly cancer patients who did not give a history of immunization with polio vaccines, in children born after the vaccines were cleared of SV40, and in sera collected before the introduction of monkey kidney vaccine. The highest prevalence of antibody (27%) occurred in Indian monkey handlers. Available evidence indicates that man is probably not a primary host for SV40 infection. The lack in the USA of primates other than man and the inability to detect SV40 antibodies in sera from goats, sheep, cows and buffalos from South India suggest that the existence of nonsimian hosts of SV40 are unlikely. Recently virus strains containing SV40-neutralizing antibodies of SV40 antigens were isolated from the brains of two patients with progressive multifocal leucoencephalopathy. A papovavirus (B.K. virus) bearing a minor antigenic relation to SV40 has also been isolated from the urine of a renal allograft recipient. If additional tests establish immunological identity between these viruses and SV40, then it is possible that SV40 does infect man independently of contact with monkeys or monkey products. Screening of 1700 patients, 1300 of which had cancer, provided no evidence of a relationship between SV40 infection and human cancer. However, cancers of the urogenital tract and brain and cancers in

immunosuppressed individuals show some promise for the implication of SV40 as an etiological agent. (46 references)

- 3613 EXCRETO-URINARY CANCERS OF THE URETHRA. (Fr.) Cukier, J. (Neckar Hosp., Paris, France), J. Vacant and D. Beurton. *Vie Med* 41(4):5073-5078, 1971.

Primary cancer of the urethra in males is a rare but very serious disease which most commonly occurs in patients aged 60-69 yr. About one-third of the patients with urethral cancer have a history of chronic urethritis or gonococcal disease. The precursive relations of these diseases to cancer are undoubtedly due to malpighian metaplasia from which epidermoid cancers originate. In contrast, urethral cancer in females is more common than in men, and the only condition it appears to be associated with is kraurosis vulvae. The histology, diagnosis, clinical symptoms, extension, and treatment of these tumors are discussed. (5 references)

- 3614 BLADDER CANCERS. (Fr.) Cukier, J. (Neckar Hosp., Paris, France), D. Beurton and J. Vacant. *Vie Med* 41(4):5057-5070, 1971.

Certain chemicals, chronic infections, mechanical irritation, and urinary schistosomiasis are often associated with bladder cancer. Although aniline and benzidine were the first bladder carcinogens discovered, β -naphthylamine, 4-aminobiphenyl, and tryptophan metabolites appear to be more dangerous. For this reason, chemical workers who handle these substances should be followed closely. Unidentified carcinogens are present in urine from patients with epithelial tumors of the bladder. When injected into the bladders of animals, this urine induces epithelial tumors in 50% of the animals. Although *Schistosoma* eggs were found in 75 biopsies from 96 Egyptian patients with bladder cancer, this may not be significant since almost the entire population is infested with *Schistosoma*. Biopsy and clinical findings, the prognosis, diagnosis, and surgical treatment and radiotherapy are considered for malignant epithelial and nonepithelial tumors of the bladder. (No references)

- 3615 CANCER VIRUS THEORIES: FOCUS OF RESEARCH DEBATE. (E.) Culliton, B. J. (No Affiliation). *Science* 177(4043):44-47, 1972.

Three models currently dominate the field of viral oncogenesis in humans. The provirus hypothesis, introduced in the early 1960's, states that an RNA tumor virus infects a cell, which then incorporates the genetic information contained in the viral RNA into its own DNA and thereby acquires the capacity to produce an oncogenic virus and become transformed into a neoplastic cell. The viral genetic information is located at a single site on one chromosome.

The integration takes place using a viral reverse transcriptase which makes a DNA copy of the viral RNA. According to the oncogene hypothesis, put forward in 1969, infection of cells by C-type RNA viruses occurred millions of years ago. Every cell now contains an oncogene, a region of DNA that is normally repressed. Derepression of the oncogene by another virus, chemicals, or radiation results in production of a "transforming protein" which causes the cell to become malignant even though no viruses are produced. The provirus hypothesis, similar to the oncogene model, evolved in 1970 as a logical extension of the discovery of RNA-dependent DNA polymerase. This hypothesis holds that cancer viruses arise from proviruses--segments of genetic information randomly brought together through a variety of genetic events. The reverse transcriptase is also present in normal cells where it plays a role in differentiation. Recent evidence supports one or more of these models. Attempts to isolate a whole cancer virus from human tissues has resulted in a number of "candidate" viruses, including C-type and B-type. Molecular hybridization experiments have suggested that C-type virus information is present in human leukemias, lymphomas and sarcomas. A reverse transcriptase has been found in many leukemia patients and is associated with a high molecular wt RNA that is homologous to Rauscher leukemia virus RNA. The oncogene hypothesis has received support from experiments in which C-type viruses were induced in normal, supposedly virus-free cells. The ability of susceptible cell strains to be infected by their own virus is also consistent with the oncogene model since the oncogene would be derepressed in this state. The provirus model is supported by the finding of reverse transcriptase activity in normal embryo cells and in normal PHA-stimulated lymphocytes. (No references)

- 3616 HEALTH HAZARDS OF ASBESTOS. (E.) Gilson, J. C. (Llandough Hosp., Penarth, England). *Composites* 3(2):57-59, 1972.

Inhalation of asbestos dust, which has been recognized as an occupational hazard for over 50 yr, causes fibrosis of lung tissues (asbestosis), especially the respiratory bronchioles and visceral pleura, resulting in reductions in inspiratory capacity, tissue compliance and oxygen perfusion. Asbestos workers have an increased risk of developing lung cancers, including bronchial carcinoma and mesothelioma. During the last ten yr there has been a real increase in the incidence of mesothelioma in persons exposed to asbestos. Mesotheliomas are characterized by a long interval (20 to 50 yr) between first exposure to asbestos dust and the detection of cancer, with cigarette smoking apparently playing no part in the etiology. Asbestos dust has also been shown to cause formation of asbestos corns on the fingers, but no cancers of the skin relatable to asbestos have been reported. Risk from asbestos is limited to inhalation of fibers 5-100 μ m long. Although asbestosis and bronchial cancers can be caused by all types of commercially used asbestos (amosite, anthophyllite, chrysotile, and crocidolite), risk of developing these tumors

is greatest with crocidolite and lowest with chrysotile. Risk is lowest in mining and increases along the manufacturing process as exposure to dust increases. The risk of asbestosis and bronchial cancer also appears to be related to the degree of exposure to asbestos; evidence for a dose-response relationship is less clear for mesothelioma. (15 references)

- 3617 THE FATE OF CARCINOGENIC HYDROCARBONS IN THE LUNG. (Ger.) Brockhaus, A. (Duesseldorf U., West Germany), R. Tomingas, W. Dehnen, F. Pott and E. G. Beck. *Prax Pneumol* 25(9):519-526, 1971.

The particle size of polycyclic hydrocarbons and the extent to which they are deposited in human lungs were investigated in experiments in rats, using a mixture of benzpyrene and dust (injected into the lungs) from various inhabited areas. The benzpyrene content in the animal lungs decreased quite rapidly with time. An injection of a suspension of 200 µg of benzpyrene mixture caused a rapid increase in the blood level of benzpyrene (in the first hr), followed by a slow decrease. An enzymatic degradation of benzpyrene in the lung was therefore postulated. *In vitro* studies demonstrated alveolar macrophages in guinea pig lungs, immediately and three hr following incubation with the benzpyrene mixture. Thus, it was established that the benzpyrene enters the lungs together with the dust particles; in the lungs, the dust is separated from the benzpyrene, which is metabolized in the lungs or transported to the liver. The rapid destruction of the benzpyrene in the lungs of experimental animals explains why it is difficult to develop lung carcinoma in animal experiments. Other hydrocarbons, as well as smoke and dust, contribute to the complexity of the effects in man. Animal experiments have shown that benzpyrene stays for a longer interval of time in lungs that have been damaged before benzpyrene exposure. (9 references)

- 3618 EXPERIMENTAL TRANSPLACENTAL BLASTOMOGENESIS AS A MEANS FOR THE STUDY OF TUMOR ETIOLOGY AND PATHOGENESIS IN CHILDREN. (Rus.) Hapalkov, N. P. (Petrov Res. Inst. Onkol., Leningrad, USSR). *Vopr Onkol* 17(8):3-15, 1971.

Published experimental data on embryonal responses to nitroso compounds during the fetal development are summarized. Embryotoxic and teratogenic effects of the following highly blastomogenic nitroso com-

pounds were studied in 1300 pregnant rats: nitroso-dimethyl-, -diethyl-, -dipropyl-, and -dibutylamines; nitroso-methyl-, and ethylanilines; nitroso-methyl-, -ethyl-, -propyl-, and dimethylureas; and nitroso-methylurethane. Dialkylnitrosamines in various doses had no teratogenic or embryotoxic effects. Strong embryotoxic and teratogenic effects were exhibited by nitrosoalkylureas, especially in the first and second weeks of embryogenesis. Nitrosomethylurea showed a high incidence of various neoplasms in the last third of the embryogenesis period. Nitrosoethylurea caused tumors of the nervous system. Nitroso-methylurethane (10 mg) had a teratogenic effect ($91 \pm 4.0\%$) only when it was administered intraplacentally, and not i.p. or i.v. Nitrosodiethylamine caused multiple neoplasms in pre- and postnatal periods. Nitrosomethylurea, when combined with nitrosodiethylamine, showed a stronger transplacental effect, causing lung adenocarcinomas more intensively than methylurea alone. The character of effects (lethal, teratogenic, carcinogenic) depended on the stage of embryogenesis, the doses of the substances, and the species of animal. (56 references)

- 3619 NASOPHARYNGEAL CARCINOMA IN NON-CHINESE POPULATIONS WITH SPECIAL REFERENCE TO SOUTH-EAST ASIA AND AFRICA. (E.) Muir, C. S. (Int. Agency Res. Cancer, Lyons, France). *Int J Cancer* 8:351-363, 1971.

Age-adjusted morbidity rates/100,000/annum for nasopharyngeal carcinoma (NPC) in overseas Chinese, indigenous South East Asian populations, African populations, and migrant groups in Hawaii and Israel were reviewed in relation to the possibility of an unknown environmental factor acting on genetically susceptible populations. For the overseas Chinese, the rates are 10 to 20/100,000/annum for males and 5 to 10 for females. NPC is also fairly common in non-Chinese mongoloid groups in South East Asia. The data for Algeria, Tunisia, and the Sudan strongly suggest a moderate elevation of risk in these countries. NPC does not appear unduly common in Kenya or Uganda but there are differences between ethnic groups in these countries which may be related to environmental factors. In Hawaii, NPC incidence is raised for all ethnic groups, the rate (7.8) for male Hawaiians approaching that for male Chinese (10.4). In Israel, the incidence is higher in the Arab population and in Jews born in Africa or Asia than in Israel-born Jews or Jews born in America or Europe. The trend for NPC to be commoner in South East Asian groups with admixture of Chinese blood is exemplified by NPC incidence in Singapore, where the rates for male and female Chinese are 20.2 and 9.0, resp., while those for the mongoloid Malays are 5.8 and 2.0, resp. By contrast, the rates for the caucasoid Indians and Pakistanis are 0.2 and 0. It is unlikely that these differences are artefactual. (49 references)

- 3620 PUBLIC HEALTH HAZARDS FROM ENVIRONMENTAL CHEMICAL CARCINOGENS, MUTAGENS AND TERATOGENS. (E.) Hueper, W. C. (Ft. Myers, Fla.). *Health Phys* 21(5):689-707, 1971

Environmental chemical cancer hazards form together with radiation cancer hazards the principal segments of the human environmental spectrum of carcinogenic risks. The cancer hazards from both types of carcinogenic agents have been rising during the past 75 yr because of the growing contamination of the human environment with products and wastes of modern industry. This development is responsible for the moderate to marked increases in frequency of certain cancers in many industrialized countries and for the shifts in age and sex distribution of certain cancers in general or circumscribed population groups. Since carcinogenic effects on cells are largely irreversible and thus persistent and cumulative when repeated, exposure to even small doses of carcinogens sustained over long periods in a carcinogenically polluted environment create definite cancer risks. The concept of a "safe" dose for carcinogens is without scientific basis, is deceptive and, if legally adopted, represents a potentially highly dangerous public health policy. While protecting special economic and professional interests, its application tends to raise gradually and insidiously the level of carcinogenic contamination of the human environment. There does not exist moreover a reliable method or procedure for determining and defining a "safe" dose. All avoidable environmental carcinogens therefore should be eliminated and prevented from entering the human environment. All unavoidable carcinogenic risks should be reduced to the lowest possible minimum and the exposed individuals should be kept under life-long medical surveillance for the detection of precancerous and early cancerous lesions which might result from such contacts. (99 references)

- 3621 AFLATOXINS: POTENT FOOD POISONS AND CARCINOGENIC COMPOUNDS. (E.) Elmund, G. K. (Colorado St. U., Fort Collins), T. C. Brewster and A. T. Tu. *J Chem Education* 49(6):398-399, 1972.

Aflatoxins are produced by the fungus, *Aspergillus flavus*. Although numerous foods can support growth of the fungus, the most common substrates are grains, coconuts and oil seeds. Aflatoxins have a pentacyclic structure and are classified as highly substituted coumarins. Of the eight confirmed structures, aflatoxin B₁ is the most toxic, carcinogenic and prevalent. Present evidence indicates that the aflatoxins are synthesized from acetate precursors. Feeding of aflatoxins to vertebrates primarily causes liver damage and especially proliferation of bile duct cells. Aflatoxins are primarily retained in the liver and initially suppress protein synthesis in, and reduce RNA content of, the liver cells. It has been reported that injection s.c. with 2 µg of a mixture of B₁ and G₁ produced tumors in five of six rats at the site of injection; when

aflatoxin was administered to rats over a period of nine weeks, the incidence of liver tumors was 100%. In addition to the liver, aflatoxins have been shown to induce neoplasms in stomach, kidneys, lungs, salivary glands, mesenchymal tissue, brain, lymphatics, skin, pituitary, adrenal cortex, mammary glands, testis and the uterus of rats. Aflatoxins or their metabolites bind to DNA and affect DNA replication, transcription into RNA, and subsequent translation of the messenger RNA into protein. (19 references)

- 3644 EFFECT OF TUMOR PROMOTERS ON CELL KINETICS IN MOUSE EPIDERMIS. (E.) Frankfurt, O. S. (Inst. Chem. Physics, Moscow, USSR) and E. Raitcheva. *J Nat Cancer Inst* 49(1):131-137, 1972.

The tumor promoters Tween-60 and croton oil were applied on the skin of normal control C3HA inbred female mice and of mice pretreated at the same site one month before by a single topical injection of 7,12-dimethylbenz(a)anthracene (DMBA). The proliferative response of the treated epidermis was estimated from autoradiographs of skin sections taken after i.p. injection of ^3H -thymidine. The number of cells synthesizing DNA in the basal layer increased 12 hr after application of the tumor promoters and was highly elevated after 72 hr. DNA-synthesizing cells also appeared among mature cells. The labeling index (% of cells labeled) for basal cells in DMBA-treated epidermis was significantly higher than in controls 12-16 hr after application of the tumor promoters. During the period of active proliferation, the mitotic cycle, as estimated by the method of labeled mitoses, was 10 hr both in normal and DMBA-treated epidermis (eight times shorter than normal, untreated epidermis). All phases of the cell cycle were shortened, especially G_1 . Cell maturation, as measured by transition of labeled cells from the basal layer into the layer of spinous cells, was accelerated in the epidermis stimulated by the tumor promoters. The number of cells per mm length of epidermis increased by 48 hr after application of tumor promoters. The increase was due to an increase in the number of mature cells only and appeared to be more pronounced in DMBA-treated skin. It is hypothesized that the action of tumor promoters on DMBA-treated epidermis leads to the selection of cells with a shortened G_1 phase, which is possibly associated with a weakened response to the factors regulating cell proliferation.

- 3645 THE SUGAR CONTENT AND THE pH OF THE SMOKE OF CIGARETTE, CIGAR AND PIPE TOBACCOS IN RELATION TO LUNG CANCER. (E.) Elson, L. A. (Inst. Cancer Res., Sutton, England), T. E. Betts and R. D. Passey. *Int J Cancer* 9(3):666-675, 1972.

Over 150 brands of cigarettes from more than 30 countries were used for estimation of tobacco sugar content and for determination of smoke pH. The results were compared with similar estimates from cigar and pipe tobaccos. Sugar content of cigarette tobacco was related to smoke pH. An increase in sugar content from below 1% to about 8% decreased the pH from 8-9 to about 5. Increasing the sugar content from 8-20% decreased the pH by less than one unit. The smoke from cigarettes with a high sugar content (containing a large proportion of flue-cured tobacco) showed a progressive increase in acidity during the course of smoking, whereas that of cigarettes with low sugar content (mainly air-cured tobacco) showed a progressive decrease in acidity. Filters had no significant effect on the direction of pH changes of the smoke. Cigar tobacco, associated with a lower incidence of lung cancer than cigarette tobacco, gave

a smoke with a progressive decrease in acidity. The mean pH of smoke for all tobaccos was greater when the tobacco was smoked in a pipe than when smoked in the form of a cigarette. Rats exposed to nicotine vapors at alkaline pH values showed greater pharmacological effects and more severe signs of nicotine toxicity than rats exposed to nicotine aerosols at acid pH values. The lower lung incidence in cigar and pipe smokes is possibly related to the fact that nicotine is more readily absorbed in the form of the free base (at alkaline pH) than in the form of a stable salt (at acid pH). The incidence of lung cancer in cigarette smokers may be reduced by raising the pH of the smoke to a "safer" level by suitable additives such as urea or guanidine salts.

- 3646 MUTATION AND TRANSFORMATION OF CULTURED MAMMALIAN CELLS BY N-ACETOXY-N-2-FLUORENYL-ACETAMIDE. (E.) Huberman, E. (Natl. Cancer Inst., Bethesda, Md.), P. J. Donovan and J. A. DiPaolo. *J Nat Cancer Inst* 48(3):837-840, 1972.

N-2-fluorenylacetamide (FAA) and its metabolic derivatives, N-hydroxy-N-2-fluorenylacetamide (N-hydroxy-FAA) and N-acetoxy-N-2-fluorenylacetamide (N-acetoxy-FAA), were studied in two cell systems: Chinese hamster for toxicity and mutagenicity and Syrian hamster for toxicity and transformation. Cytotoxicity (ratio of cloning efficiency of treated and control cells), mutagenicity (8-azaguanine-resistant colonies/ 10^5 cells) and transformation frequency (ratio of colonies exhibiting crisscross pattern to surviving treated colonies) increased with concentration and degree of reactivity of the derivative FAA. In both cell systems, N-acetoxy-FAA was the most cytotoxic compound and FAA the least toxic. N-acetoxy-FAA was also highly mutagenic to the Chinese Hamster cells and produced the greatest frequency of transformation in Syrian hamster cells. N-hydroxy-FAA produced a low frequency of transformed or drug-resistant colonies only at high concentrations. FAA was nonmutagenic and had a very weak transforming activity at all doses tested. These results suggest a positive correlation between mutagenicity and transformation.

- 3647 DIMETHYLCARBAMYL CHLORIDE, A MULTIPOTENTIAL CARCINOGEN. (E.) Van Duuren, B. L. (New York U. Med. Ctr., N.Y.), B. M. Goldschmidt, C. Katz and I. Seidman. *J Nat Cancer Inst* 48(5):1539-1541, 1972.

Dimethylcarbamyl chloride (DCC), a urethan-related derivative of carbamic acid used in the manufacture of herbicides, pesticides and anthelmintics, was tested for carcinogenicity in female ICR/Ha Swiss mice by application to skin (2 mg, three times weekly) and by s.c. injection (5 mg, once weekly). After one yr, 68% of the animals treated by skin application had tumors; of these 46% were papillomas and 22% were carcinomas. S.c. injection produced a 72% incidence of local sarcomas. A low incidence of papillary tumors of the lung

was observed at autopsy in the animals given DCC by topical application (8% incidence) and by s.c. injection (4% incidence). No lung tumors were seen in the control groups. It is suggested that DCC is a direct-acting acylating agent whose active form is its cation and that it may constitute a potential occupational hazard.

- 3648 TRACE ELEMENTS THAT ACT TO INHIBIT NEOPLASTIC GROWTH. (E.) Pories, W. J. (Case Western Reserve U. Sch. Med., Cleveland, Ohio), E. G. Mansour and W. H. Strain. *Ann NY Acad Sci* 199:265-273, 1972.

Several trace elements have been reported to inhibit neoplastic growth by a number of mechanisms. Arsenic has been shown to decrease significantly the incidence of adenomas and carcinomas of the lung in mice. Several reports suggest that copper inhibits chemically induced carcinogenesis and that it potentiates the anticancer effects of various alkylating agents. Iodine has proven so far to have the most practical application to anti-tumor technology. In small amounts it prevents goiter and in larger amounts, the growth of tumor. Platinum compounds have the ability to stop cell division and have been reported to act synergistically with alkylating agents. Experiments have suggested that platinum may have a broad antitumor spectrum. Selenium is able to inhibit chemically induced carcinogenesis in rats. In addition, human cancer death rates are apparently higher in areas with low selenium levels. Zinc, which is essential for normal proliferative processes, also plays an important role in tumor growth. The survival of Walker 256 carcinosarcoma, Lewis lung tumor and leukemia-bearing rats and mice fed a zinc-deficient diet was significantly increased and the growth of tumors was decreased compared with that of the controls. Radioactive zinc is localized preferentially in various mouse cancers, possibly due to a relatively slower turnover compared with normal body tissues, and this fact has provided one successful approach to antitumor therapy in animals. Although the role of zinc in human cancers has not been explored, low serum levels have been reported in leukemia, Hodgkins disease, bronchial carcinomas and a variety of other tumors.

- 3649 EFFECT OF AFLATOXIN ON COMPLEMENT ACTIVITY IN GUINEA PIGS. (E.) Thurston, J. R. (Veterinary Sci. Res. Div., U.S. Dept. Agriculture, Ames, Iowa), J. L. Richard, S. J. Cysewski, A. C. Pier and C. K. Graham. *Proc Soc Exp Biol Med* 139(1):300-303, 1972.

Eleven groups of guinea pigs were dosed once daily with partially purified aflatoxin in measured amounts per os for 20 days. Blood samples were obtained from each animal prior to treatment and on day 21; complement titrations were done within 48 hr after collection. All animals were sacrificed after the

second blood sampling and histological examination carried out on liver tissue. A daily dose of aflatoxin equivalent to 0.03 mg or greater of fraction B₁ resulted in significant depression of complement activity associated with changes in the liver. A daily intake equivalent to 0.015 mg or greater B₁ caused a significant reduction in weight, showing the general condition of guinea pigs was more responsive to aflatoxin than either complement activity or liver change. Considerable individual variations in complement titers, weights and liver changes were noted among the guinea pigs.

- 3650 EXCRETION OF AFLATOXIN BY FROGS AFTER IMPLANTATION WITH *ASPERGILLUS FLAVUS*. (E.)

Brewster, T. C. (Dept. Microbiol., Colorado State U., Fort Collins) and D. W. Grant. *J Infectious Dis* 125(1):66-68, 1972.

Results of 20 experiments designed to determine if aflatoxins are formed *in vivo* in *Rana pipiens* implanted with *Aspergillus flavus* are reported. Frogs implanted with viable mycelia of a toxigenic isolate of *A. flavus* excreted 50% more aflatoxin than control animals bearing autoclaved implants. The ratio of aflatoxin B to G in excretions from frogs implanted with live mycelia was approximately 1:2, while for controls it was close to 1:1. In both live and autoclaved mycelia, the ratio was the same before implantation. The elevated amounts of aflatoxin G excreted by frogs with live implants seemed to demonstrate *in vivo* formation. Experiments with ¹⁴C glucose provided evidence that partial or total synthesis of aflatoxin occurred during the parasitic existence of *A. flavus*. These findings suggest that *A. flavus* retains its ability to produce aflatoxin in frogs with simulated aspergillosis.

- 3651 LYMPHOMAS IN THE WISTAR RAT AFTER INTRA-PLEURAL INOCULATION OF SILICA. (E.)

Wagner, M. M. F. (Llandough Hosp., Penarth, Wales) and J. C. Wagner. *J Nat Cancer Inst* 49(1):81-91, 1972.

Standard and specific pathogen-free (SPF) Wistar rats received a single i.p. injection of alkaline-washed crystalline silica (<5μ diameter), and the subsequent development and distribution of silicotic nodules and tumors was studied. The distribution of nodules was the same in standard and SPF rats. Macroscopically, they were limited to the pleural cavity and were seen throughout the mediastinum, on the outer pericardial surface, surrounding the aorta and esophagus, and on the pleural surface of the diaphragm. Silica crystals were observed microscopically in the liver and spleen. Apart from those animals which developed malignancies, 21 standard and 30 SPF rats developed granulomas. Most tumors in both groups occurred between 300 and 1000 days after silica injection. Thirty nine of 96 SPF rats and 31 of 94 standard rats developed reticuloendothelial

tumors, most of which were composed of malignant histocytes. Five tumors among the SPF rats were malignant lymphomas. Spindle cell sarcomas were seen in both the standard and SPF groups. Malignant tumors were observed in the mediastinum, pericardium, diaphragm, lungs, liver and spleen. Early malignant change often occurred near silicotic nodules. Thymic involvement was never seen. The tumors occurring after silica inoculation differed histologically from those reported to occur after i.p. inoculation of asbestos.

- 3652 AIRCRAFT ENGINES AS A SOURCE OF CARCINOGENIC POLLUTION OF THE ENVIRONMENT (BENZO (a)PYRENE STUDIES). (E.) Shabad, L. M. (Inst. Exp. Clin. Oncology USSR Acad. Med. Sci., Moscow) and G. A. Smirnov. *Atmos Environ* 6:153-164, 1972.

Benzo(a)pyrene (BP) concentrations in soot and exhaust gases from turbojet and piston aircraft and in soil, vegetation and snow near airports were determined by spectrofluorescent techniques. The amount of BP emitted by the aircraft depended on engine working regime and the character of fuel combustion. Soot from a piston engine contained 250 µg/kg BP and that from a jet engine 350 µg/kg. BP concentrations in jet exhaust gases were 2-4 mg/min. Levels of BP in the atmosphere, soil, vegetation and snow ranged from 0.28 µg/kg to 182 µg/kg. The carcinogenicity of aircraft soot containing 0.1% BP was established in experiments with hybrid F₁ mice. Four groups of mice received applications of test materials three times a week in the following series: Group I (33 mice) treated with turbojet soot; Group II (33 mice) treated with piston engine soot; Group III (34 mice) treated with BP extract in benzol; and Controls (20 mice) treated with benzol alone. Tumors developed in all mice except controls 11-13 wk after onset of treatment. Nine months after the beginning of the experiment the surviving animals (29 in each test group and all controls) were sacrificed and their tissues examined. All mice except controls had epithelial tumors and the tumors were malignant in all but three animals. To control the possible action of carcinogenic aviation exhausts on man, consideration should be given to improving the efficiency of fuel combustion in aircraft engines.

- 3653 CARCINOGEN DIMETHYLNITROSAMINE PRODUCED *IN VIVO* FROM NITRITE AND AMINOPYRINE. (E.) Lijinsky, W. (U. Nebraska Med. Ctr., Omaha) and M. Greenblatt. *Nature New Biol* 236(67):177-178, 1972.

The *in vivo* production of dimethylnitrosamine (DMN) was studied in male MRC (Wistar-derived) rats. Groups of rats were given 35 mg of aminopyrine, 40 mg of sodium nitrite or aminopyrine plus sodium nitrite by gastric intubation. After 68 hr the livers of rats receiving aminopyrine or nitrite alone showed no changes, but the livers of rats

fed aminopyrine plus nitrite all showed severe centrilobular liver necrosis typical of the effect of DMN. Animals treated for three consecutive days with aminopyrine plus nitrite died one hr after the last feeding. On autopsy, the livers were swollen and dark red. Microscopically, blood ascites and severe liver necrosis was seen. Serum SGPT levels, an index of liver necrosis, were increased two- to four-fold in rats receiving the combined treatment. No significant hepatic alterations were noted in animals receiving aminopyrine or nitrite alone. These results indicate that a significant amount of DMN was formed *in vivo* in rats receiving aminopyrine plus nitrite. The lack of a necrotic liver response in animals fed nitrite plus dimethylamine indicates that the formation of DMN from aminopyrine and nitrite was not due to nitrosation of dimethylamine produced from aminopyrine by hydrolysis. These results suggest that the ingestion by humans of aminopyrine when nitrite is present in the stomach may constitute a hazard.

- 3654 THE HISTOCHEMICAL DEMONSTRATION OF POLYADENYLIC ACID HYDROLASES IN RAT LIVER DURING AZO DYE CARCINOGENESIS. (E.) Daoust, R. (Dept. Anatomy, U. Montreal, Canada). *J Histochem Cytochem* 20(7):536-541, 1972.

Films of polyadenylic acid (poly A) were exposed to liver sections from 4-dimethylaminoazobenzene (DAB)-fed male albino Wistar rats in order to determine whether the nucleases acting on these films, like the RNase previously reported, were depressed during carcinogenesis. Normal liver parenchyma gave a positive reaction for poly A hydrolases which was particularly intense in periportal areas. Livers from animals fed the basal control diet (without DAB) showed a similar distribution of enzyme activity but were generally more active than normal livers. In DAB-fed rats, the nodules of hepatic tissue gave intense reactions while the trabeculae of bile ducts and connective tissue, as well as the necrotic areas, were negative. The formation of hyperbasophilic foci at later stages of DAB feeding was accompanied by a loss of poly A hydrolase activity. The hepatomas, which were apparently derived from such foci, showed weak or negligible activity. Thus, the change in RNases, as previously reported, and in poly A hydrolases occurred at different stages of the carcinogenic process. The loss of RNase activity preceded the neoplastic transformation while the decrease in the activity of poly A hydrolases was closely associated with tumor formation; however, the induced tumors were deficient in both types of nuclease activity.

- 3655 THE EFFECT OF VARYING THE LENGTH OF THE NURSING PERIOD ON THE POSTPARTUM GROWTH OF CHEMICALLY INDUCED RAT MAMMARY TUMORS. (E.) McCormick, G. M., II (U. Tennessee Med. Units, Memphis). *Cancer Res* 32:1574-1576, 1972.

The effect of varying the length of the nursing period on the regression of 7,12-dimethylbenz(a)-anthracene (DMBA)-induced rat mammary carcinomas was studied. Virgin female Sprague-Dawley rats received 20 mg DMBA by gastric intubation. Eighteen days after DMBA feeding, the rats were allowed to breed. On the first day postpartum, all litters were adjusted to six pups, and the rats were divided into three groups which nursed 7, 14 and 21 days, resp. All rats developed single or multiple palpable mammary tumors during their pregnancy. The rate of tumor regression was inversely related to the duration of the nursing period. Six of 13 tumors regressed in animals which nursed for 21 days, while 10 of 14 tumors had regressed by the 21st day postpartum in animals nursing for 14 days and 13 of 15 had regressed in the animals which nursed for only seven days. In all instances, the remainder of the tumors which did not regress increased in size. When animals bearing multiple tumors nursed for only seven days, all tumors regressed. No regression was noted in multiple tumor-bearing animals nursing for 14 or 21 days. No tumors in any of the groups regressed during the first seven days. New tumors appeared in all groups following parturition, with the time of tumor appearance apparently related to the length of the nursing period. While two tumors appeared during the 21-day nursing period, no tumors appeared during the first 21 postpartum days in animals which nursed for seven or 14 days. These results further strengthen the concept that maintenance of growth of chemically induced mammary rat tumors during the postpartum period depends on the continual presence of the nursing stimulus.

- 3656 CELL FUNCTION: ITS IMPORTANCE IN CHEMICAL CARCINOGENESIS. (E.) Becker, F. F. (New York U. Sch. Med., New York). *Fed Proc* 30(6):1736-1741, 1971.

Cell function in relation to chemically produced neoplasms is reviewed with emphasis on experimental findings in the fields of hepatocarcinogenesis and plasma cell tumors. A hypothetical model of carcinogenesis is derived in which extreme functional demand interacts with chronic cell proliferation in a milieu of appropriate genetic susceptibility to produce malignant alteration. Hepatic nodules produced by ingestion of N-2-fluorenylacetamide (2-FAA) were studied as preneoplastic nodules. Immune electrophoresis radioautography showed clear suppression of protein synthesis in early nodules; levels of albumin and complement were greatly reduced or albumin was totally absent. Haptoglobulin was also frequently absent. Restoration toward the pattern of normal livers was seen in later nodules. Approximately 10% of the cells in early nodules had breaks or gaps in their chromosomes, while the chromosomes of later nodules were intact. Inbred BALB/c mice injected i.p. with mineral oil had a high incidence of functioning plasma cell tumors. The tumors showed three stages of development: 1) the initial response was formation of granulomatous structures

with normal-appearing plasma cells; 2) later abnormal plasma cells appeared in the granulomas, producing abnormal-type proteins within the tumor which were undetectable in the peripheral blood; and 3) the terminal stage was the proliferation and spread of the myeloma cells with their unique protein detectable in the peripheral blood. In germ-free BALB/c mice, the same procedure produced lymphoreticular sarcomas instead of plasma cell tumors. The hypothesis advanced emphasizes that although loss of cell function may be secondary to tumor progression and relatively unimportant in this sequence, an intense, prolonged functional demand may govern the carcinogenic evolution of selected tissues.

- 3657 MUTATIONS INDUCED IN *HAEMOPHILUS INFLUENZAE* BY TRANSFORMATION WITH NITROSOGUANIDINE-TREATED DNA. (E.) Kimball, R. F. (Oak Ridge Natl. Lab., Tenn.) and J. K. Setlow. *Mutat Res* 14(2):137-146, 1972.

DNA treated with *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG) was used to induce mutations in untreated *Haemophilus influenzae*. Two strains of bacteria were used: Rd (wild type) and Rd (DB112), a UV-sensitive excisionless strain obtained from transformation of Rd with DB112 DNA. Both strains were exposed to MNNG and tested for resistance to four drugs. The frequencies for mutation to kanamycin and viomycin resistance were one to two times higher than those to novobiocin and erythromycin resistance. Highly competent (63% transformation to streptomycin resistance) and exponentially growing cultures were exposed simultaneously to 1.9 mM MNNG for 3, 6, and 9 min, grown to A₆₇₅ of 0.8, frozen and tested for resistance to 0.8 µg/ml novobiocin. No clear difference existed between the induced mutation frequencies in the two cultures. When Rd (DB112) was the recipient no definite evidence for induced mutation at any locus was found. Experimental results showed that *H. influenzae* can be induced by incorporation of MNNG-treated DNA into the genome. Proof of mutation, although at a rather low level, was found for the two loci which are quite close to the streptomycin marker used in selection of transformants. The level of mutation when transforming DNA was treated with MNNG was low compared with mutation of whole cells under similar conditions.

- 3658 BIOCHEMICAL STUDY OF THE PASSAGE OF 3-METHYLCHOLANTHRENE, A CARCINOGEN, THROUGH THE PLACENTA IN MICE. (Fr.) Guibert, D. (Nat. Inst. Applied Sci., Lyon, France), B. Duperray, H. Pacheco, L. Tomatis and V. Turusov. *Therapie* 26(5):1027-1038, 1971.

The permeability of the placenta of mice to 3-methylcholanthrene (MCA), the distribution of MCA in mouse tissues, changes in MCA levels with time in the fetus, and the quantity of MCA metabolites in the fetus were studied. On the 17th day of

gestation, OF mice were given a total of 10 mg MCA in olive oil through an esophageal sound in three equal doses at six-hr intervals or single doses of 1 or 3.3 mg. Within 3-34 hr after the last dose was given, mice were anesthetized and the fetuses were removed and dissected, taking care that fetal tissues were not contaminated with blood from the mother. Tissues to be studied were extracted continuously with benzene, and MCA was determined quantitatively by thin-layer chromatography, gas chromatography, and radioactive labeling with ^{14}C -MCA. All operations were performed in the dark to prevent photochemical degradation. Offspring were found to contain about 1/1000 of the dose of nonmetabolized MCA administered to the mother. In both mothers and offspring the largest amounts of nonmetabolized MCA were found in the thymus, lungs, and liver. Less MCA was found in the offspring of mothers given 10 mg MCA than in those given smaller doses. This is accounted for by the less complete intestinal absorption of the last two doses of MCA. Determinations of MCA in the blood showed that six hr after administration of the last dose, 50% of MCA in the blood of mothers was nonmetabolized, while only 10% was nonmetabolized in the blood of the offspring.

- 3659 EFFECT OF CARCINOGENS ON DNA. ACTION OF 7-BROMOMETHYLBENZ(a)ANTHRACENE. (E.) Michelson, A. M. (Inst. Biol. Physico-Chem., Paris, France) and F. Pochon. *Biochimie* 54(1):17-24, 1972.

Reactions of 7-bromomethylbenz(a)anthracene (BMBA) with DNA, hybrid DNA-RNA and reovirus RNA-RNA, and DNA complexes with other molecules were investigated with regard to the nature of double helices and the products of cross-linking. The percentage of substitution in modified DNAs was determined by UV absorption methods. In the reaction of BMBA with DNA (*Micrococcus lysodeikticus*), an increase in salt concentration of the reaction mixture increased the extent of binding of the carcinogen. Thermally denatured DNA reacted with BMBA to a lesser degree than native DNA, with cross-linking by the DMBA almost disappearing. In contrast to DNA-DNA, hybrid DNA-RNA and reovirus RNA-RNA showed low reactivity with BMBA; the low reactions can be explained by differences in helical geometry of these polynucleotides. The experimental results indicate that the large groove of DNA is an important factor in the DNA-BMBA reaction. Covalent fixation of BMBA to DNA inhibited complex formation with polylysine, with a probable conformational change of the DNA occurring. No inhibition of actinomycin binding was observed with modified DNA compared with unmodified DNA. Cross-linking of DNA strands occurred upon reaction with BMBA; a large excess of BMBA produced a considerable increase in cross-linking. Irradiation of DNA-methylbenzanthracene at 365 nm in aqueous buffer at 5°C produced decreased resolution of the carcinogen absorption bands, partial degradation of the DNA, a 90% decrease in intensity of fluorescence, and an increase in the proportion of cross-linking.

- 3660 ENZYMATIC METABOLISM OF CYCLOPHOSPHAMIDE AND NICOTINE AND PRODUCTION OF A TOXIC CYCLOPHOSPHAMIDE METABOLITE. (E.) Hill, D. L. (Kettering-Meyer Lab., Southern Res. Inst., Birmingham, Ala.), W. R. Laster, Jr. and R. F. Struck. *Cancer Res* 32(4):658-665, 1972.

The enzymes involved in the conversion of cyclophosphamide to its major excretory metabolites were characterized; the metabolism of nicotine was studied as a model for cyclophosphamide conversion. Standard reaction mixtures for cyclophosphamide and nicotine oxidation were prepared containing liver microsomes from DBA/2 mice and TPNH. Cyclophosphamide was converted by mouse liver microsomes into two metabolites (A and C). Metabolite C was present at 15 to 20% of Metabolite A. A and C were converted into a secondary metabolite (B) by an enzyme in the soluble portion of mouse liver. Nicotine was likewise converted into two products (M and N); addition of the supernatant fraction to this system quantitatively converted Metabolite M to Metabolite O but had no effect on Metabolite N. The K_m for oxidation of cyclophosphamide (formation of Metabolite A) was 0.5 mM; carbon monoxide, nicotine, atropine, ephedrine, apomorphine, cocaine, tremorine, phenobarbital, cytochrome c, 2-diethylaminoethyl-2,2-diphenylvalerate and testosterone inhibit the reaction. The enzyme of the supernatant fraction responsible for conversion of cyclophosphamide Metabolites A and C to Metabolite B and for conversion of nicotine Metabolite M to O was selectively inhibited by aldehydes. The supernatant fraction could be replaced by purified rabbit liver aldehyde oxidase. Only liver and lung tissue homogenates could oxidize cyclophosphamide; lung tissue could not convert A to B. Lung homogenates catalyzed the formation of M from nicotine. The initial products of cyclophosphamide oxidation were toxic to tumor cells in *in vitro* tests. For inhibition of clone formation, the products were more than 300 times as effective as cyclophosphamide and about five times as toxic as Metabolite B. Metabolite A was identified as aldophosphamide; Metabolite B was identified as 2-carboxyethyl N,N-bis-(2-chloroethyl) phosphorodiamidate (carboxyphosphamide).

- 3661 SOME FACTORS DETERMINING THE SITE OF TUMORS AND RESISTANCE OF THE RAT STOMACH TO CARCINOGENIC HYDROCARBONS ENTERING THE STOMACH VIA THE DIGESTIVE SYSTEM. (Rus.) Arkhipov, G. N. (Inst. Nutr., Moscow, USSR). *Vestn Akad Med Nauk SSSR* 27(2): 27-30, 1972.

Experiments were carried out with three groups (32 in each group) of hybrid female rats. Group I was made up of intact animals. Methylcholanthrene (MA) in olive oil (0.05 mg/0.1 ml) was administered to Group II by catheter in the esophagus twice daily. Group III received the same carcinogen, but were fasted the day before administration of MA (0.1 mg/0.2 ml). MA was administered six times/wk for seven months to Group II and III. The animals were killed 14 months after the beginning of the experiment and were examined for tumors. Seven rats in Group I, three in Group II, and nine in Group III died before

the end of experiment. Tumors were induced in various organs and tissues, including the liver and mediastinum (2/Group III) and forestomach (3/Group II), while no tumors were observed in the gastric mucosa. Experiments on other rats showed that large amounts of spontaneous gastric secretion and special contractions of the fasted stomach were factors accelerating the evacuation of MA into the intestine, thereby inhibiting the tumor growth in the stomach, including the mucosa. This explains the occurrence of tumors in the forestomach in Group II and not in Group III. Tumors were not seen in the glandular stomach in either group.

3662 EVALUATION OF THE CARCINOGENIC ACTIVITY OF SOME ANTINEOPLASTIC AND IMMUNODEPRESSIVE AGENTS IN NEWBORN SWISS MICE. (It.) Brambilla, G. (Inst. Pharmacol., U. Genoa, Italy), C. E. Caraceni, M. Cavanna and S. Parodi. *Boll Soc Ital Biol Sper* 47(14):418-422, 1971.

Azathioprine (Az; 10 and 40 mg/kg/day), methotrexate (MTX; 0.275 and 0.550 mg/kg/day), 5-fluorouracil (FU; 8.4 and 14.0 mg/kg/day), and L-asparaginase (LA; 2500 I.U./kg/day) were injected i.p. into male and female random-bred Swiss mice. LA treatment began 24 hr after birth, while treatment with Az, MTX, and FU began 48-72 hr after birth. All agents were administered for four consecutive days. Moribund mice were sacrificed, and survivors were sacrificed after 6-7 months; all animals were autopsied. Lymphogenous leukemia developed in 1/119 and pulmonary adenomas in 10/119 controls. Only the larger dose of Az caused a significant increase in lymphogenous leukemia (4/20 rats), which was characterized by leukemic infiltration of the spleen, lymph nodes, liver, kidneys, and lungs. An increased incidence of pulmonary adenomas, which was not statistically significant, was observed in rats given 8.4 mg/kg/day FU. Neither MTX nor LA had any carcinogenic activity. A relationship between sex and carcinogenic activity was found with LA: adenomas developed in 7/23 males and in only 1/25 females. The absence of carcinogenic activity with MTX, FU, and LA may be due to the short duration of treatment. These findings do not rule out the possibility that these compounds may be carcinogenic when administered for longer periods.

3663 CONDITION OF SOME ENDOCRINE ORGANS IN PATIENTS WITH UTERINE CANCER. (Rus.) Slepov, M. I. (V. I. Lenin Inst. Postgrad. Med., Kazan, USSR). *Akush Ginekol* 47(9):42-46, 1971.

Urinary estrogens, function of the adrenal cortex and thyroid, and some liver function tests were investigated in 45 women, aged 43-72 yr, with stage I and II uterine cancer. Associated diseases included obesity (25/45), hypertension (20/45), diabetes (11/45), and hormonally-active ovarian

tumors (2/45). Although a few patients excreted abnormally large quantities of total estrogens (17.4-21.0 µg/day), which may be associated with obesity, there was no significant difference between excretion of total estrogens, estrone, and estriol in menopausal patients with uterine cancer and in normal women in menopause; urinary estradiol levels were significantly increased in cancer patients. Excretion of both total and free 17-hydroxyketosteroids varied within wide limits, but the means did not differ significantly from normal values; 17-ketosteroid excretion was significantly lower than in the control group. Serum sodium levels were normal, and serum potassium levels were in the upper normal range. ¹³¹I-uptake tests, performed on 20 patients with uterine cancer, were normal in 11 cases; six patients had hyperthyroidism and three had hypothyroidism. Basal metabolism was increased in 9/20 patients. Although total serum protein values were normal, albumin levels were reduced and all globulin fractions, particularly α₂- and α-globulins, were increased. The hippuric acid excretion test showed that liver detoxification was abnormal in more than half of the patients. These abnormalities in serum proteins and liver detoxification suggest that one of the reasons for hormone imbalance in patients with uterine cancer is disturbances in liver function. This is an important etiological factor in the development of hormone-dependent tumors.

3664 VASCULARIZATION AND TUMOR GROWTH DURING CHEMICAL CARCINOGENESIS IN THE HAMSTER CHEEK POUCH. STUDIES ON VASCULAR INJECTION AND GRAPHIC OR PLASTIC RECONSTITUTION METHODS. (Fr.) Delarue, J. (Dept. Path. Anat., Paris, France), J. Mignot, T. Caulet, J. Diebold, J. P. Camilleri, M. Reynes and J. Barge. *C R Soc Biol (Paris)* 165(5):998-1000, 1971.

The cheek pouch in adult hamsters was painted three times a week with a 0.5% solution of 9,10-dimethyl-1,2-benzanthracene (DMBA) in mineral oil. Intraepithelial carcinomas *in situ* developed eight weeks after treatment was begun. Examination of thick slices after intravascular injection of India ink showed that these circumscribed vascular nodules were provided with clusters of 6-15 capillary loops which were closely associated with elongated epidermal ridges. Graphic reconstruction of one of these lesions showed that the thick covering rested on four capillary loops, three of which were abnormal, with irregularities in their courses, angulations, and varicosities. Drainage was provided by a venule; the capillary loops formed from a precapillary sinus arteriole; and deformations in the capillary loops were not associated with proliferation. Within 90-160 days after institution of DMBA treatment these vascular nodules had become tumors consisting of sessile or pedunculate polypoid masses with clusters of distended capillaries. These tumors were made up of lobes, and changes in the vascular network involved all of the various tumor lobes. A plastic reconstruction of an invasive polypoid tumor showed that the vascular network

consisted of three groups of clearly defined loops. Each of these groups was made up of 6-10 principle loops and was fed *via* a precapillary arteriole; a large venous trunk reached deep into the sub-epithelium. The presence of three elementary units in these tumors could be accounted for either by subdivision of a primary unit or by the meeting of adjacent units. Although the mechanism involved in development of these tumors could not be determined from these findings, the asynchronous development of vascular clusters in different lobules of the same tumor suggests that adjacent angions coalesce.

- 3665 CHEMICAL INDUCTION OF FOCUS-FORMING VIRUS FROM NONPRODUCER CELLS TRANSFORMED BY MURINE SARCOMA VIRUS. (E.) Aaronson, S. A. (Natl. Cancer Inst., Bethesda, Md). *Proc Nat Acad Sci USA* 68(12):3069-3072, 1971.

Several nonproducer, viral antigen-negative cell lines cloned from murine sarcoma virus (MSV)-transformed cultures were induced to produce focus-forming virus by 5-bromodeoxyuridine (BrdU). Host ranges and serologic characteristics of the induced focus-forming viruses were similar to those of the endogenous helper virus and were independent of the MSV used originally to transform the cells. The induced virus was not able to replicate as a single, infectious virus. These results indicate that genetic information for both MSV and helper murine leukemia virus was present in nonproducer rat and mouse cells transformed by MSV. Several other chemicals also induced virus in nonproducer cells but at much lower titers than BrdU. The fact that virus could not be induced by some strongly mutagenic agents implies that the inducer effect is specific and that induction is not due merely to nonspecific cell toxicity.

- 3666 DIFFERENTIAL INACTIVATION OF TRANSFORMING DNA *IN VITRO* AND *IN VIVO* BY 4-HYDROXYAMINO-QUINOLINE 1-OXIDE. (E.) Ishii, Y. (Fac. Med., Osaka U., Japan) and S. Kondo. *Mutat Res* 13(3): 193-198, 1971.

An Hcr⁻ strain, deficient for the DNA pyrimidine dimer excision-repair mechanism, and an Hcr⁺ strain of *Bacillus subtilis* were compared for susceptibility to the carcinogen 4-hydroxyaminoquinoline 1-oxide (4HAQO). Both Hcr⁻ and Hcr⁺ cells showed the same sensitivity to inhibition of colony-forming ability by 4HAQO, 4-nitroquinoline 1-oxide (4NQO), and UV irradiation. No difference was observed *in vitro* between transforming activities of DNA assayed on Hcr⁻ or Hcr⁺ cells. However, *in vivo* residual transforming activity of 4HAQO-treated Hcr⁻ cells was greater on Hcr⁺ cells than on Hcr⁻ cells. These results indicate that (1) damage induced by 4HAQO is similar to that induced by 4NQO, with both types reparable by the excision-repair mechanism; and (2) DNA damage induced by 4HAQO *in vivo* but not

in vitro is reparable by the repair mechanism. It is hypothesized that DNA damage induced by 4HAQO and 4NQO might be effected by a metabolic product common to both chemicals.

- 3667 THE ACTION OF VITAMIN B₁₅ ON THE INDUCTION OF RAT MAMMARY TUMORS WITH 9,10-DIMETHYL-1,2-BENZANTHRACENE. (Rus.) Beskrovnnii, A. M. (Kharkov Res. Inst. Endocrinol. and Horm. Chem., USSR). *Vop Onkol* 17(7):78-79, 1971.

Vitamin "B₁₅" was administered to rats in an attempt to decrease liver damage from 9,10-dimethyl-1,2-benzanthracene (DMBA) during mammary tumor induction. Female Wistar rats received three 10 mg oral doses of DMBA at 10-12 day-intervals; doses of 10 mg/day vitamin "B₁₅" were also given orally to one group for two months. Mammary tumors were observed in 95.2% of the rats who survived in the group treated only with DMBA; the latent period was 36.6 ± 14.9 days. Tumors occurred in 73% of the group treated with both DMBA and vitamin "B₁₅", the average latent period was 52.1 ± 19.4 days. Vitamin "B₁₅" did not reduce the hepatotoxic action of the carcinogen, but it did reduce tumor frequency and increase the latent periods significantly. Apparently, vitamin "B₁₅" reduces the carcinogenic action of DMBA considerably.

- 3668 POSSIBLE ROLE OF RIBOFLAVIN DEFICIENCY IN EPITHELIAL NEOPLASIA. III. INDUCTION OF MICROSOMAL ARYL HYDROCARBON HYDROXYLASE. (E.) Chan, F. C. (Amer. Hlth. Fdn., New York, N.Y.), T. Okamoto and E. L. Wynder. *J Nat Cancer Inst* 48(5):1341-1345, 1972.

Female Swiss ICR/Ha mice maintained on a riboflavin (B₂)-deficient diet for four wk had decreased activity of aryl hydrocarbon hydroxylase (AHH) in the skin and liver, as determined by a fluorometric *in vitro* assay, when compared with mice on a B₂-supplemented diet. Upon injection of riboflavin to deficient mice, or upon feeding of a normal diet, AHH activity of skin increased above that in mice fed the control diet. Application of 7,12-dimethylbenz(a)-anthracene (DMBA) topically to deficient mice increased the induced AHH activity of skin to a higher level than that of control mice. However, induction of hepatic AHH was retarded in deficient mice receiving i.p. riboflavin injections and DMBA topically.

- 3669 INFILTRATING DUCT CARCINOMA OF THE MAMMARY GLAND OF A RHESUS MONKEY AFTER ADMINISTRATION OF AN ORAL CONTRACEPTIVE: A PRELIMINARY REPORT. (E.) Kirschstein, R. L. (Natl. Cancer Inst., Bethesda, Md.), A. S. Rabson and G. W. Rusten. *J Nat Cancer Inst* 48(2):551-556, 1972.

Six mature (six- to eight-years-old) female rhesus monkeys originally imported from India and fully quarantined were given daily doses of the oral

contraceptive Enovid (1 mg/day) in orange juice. Eighteen months after the start of the experiment, one animal went into respiratory distress and died. Autopsy revealed tumor masses in the left mammary region, in the axillary and internal mammary lymph nodes and in the lungs and liver. The primary mass was identified histologically as an infiltrating duct mammary adenocarcinoma. No pathologic changes were seen in the uterus, ovaries or tubes. The remaining five monkeys continued to receive the drug and after two yr showed no clinical evidence of disease. The extreme rarity of such tumors in untreated monkeys suggests that the carcinoma was induced by Enovid; however, the possibility of spontaneous origin can not be excluded.

- 3670 CARCINOGENICITY OF DIETHYLNITROSAMINE IN *MYSTROMYS ALBICAUDATUS* (AFRICAN WHITE-TAILED RAT). Yamamoto, R. S. (Nat'l. Cancer Inst., Bethesda, Md.), R. Kroes and J. J. Weisburger. *Proc Soc Exp Biol Med* 140(3):890-892, 1972.

Male and female weanling African white-tail rats received diethylnitrosamine (50,100/or 200 ppm) in their drinking water. When death appeared imminent, the animals were killed and autopsied and their organ sections examined by light microscopy. The liver and stomach showed the greatest involvement and both sexes were equally affected. No lesions were observed in controls. All three dosage levels produced well differentiated hepatomas, bile duct adenomas and carcinomas and some gastric squamous cell carcinomas with a latent period of 22 to 42 wk. Multiple hepatomas in the same animal were not uncommon. In a number of cases liver cirrhosis was present. Although this species tolerated relatively high doses of diethylnitrosamine, tumors developed after a longer latent period than in other laboratory rodent species used for bioassay of chemical carcinogens. These results suggest that white-tailed rats are not as suitable for bioassay of chemical carcinogens as currently used rodent species.

- 3671 STRUCTURE AND ACTIVITY IN CHEMICAL CARCINOGENESIS: STUDIES OF VARIOUSLY SUBSTITUTED 7-BROMOMETHYLBENZ[a]ANTHRACENES. (E.) Dipple, A. (Chester Beatty Res. Inst., London, England) and T. A. Slade. *Europ J Cancer* 7(5):473-476, 1971.

Four 7-bromomethylbenz(a)anthracene (BMBA) derivatives were synthesized and tested for their ability to initiate papilloma formation following topical application to female Swiss S mice. The four compounds (1-methyl-BMBA, 6-fluoro-BMBA, 4-bromo-BMBA and 4-chloro-BMBA) were each applied once. Beginning two wk after application of initiator, 10 µg of the carcinogen 12-myristoylphorbol-13-acetate was applied to the same site twice a week for 25 total applications. The incidence of papilloma formation was not as high as that previously reported for 7-bromomethyl-12-methylbenz(a)anthracene (4.1 papillomas

per mouse). 6-Fluoro-BMBA, 1-methyl-BMBA and the parent compound produced an incidence of 1.2 papillomas per mouse. The 4-chloro- and 4-bromo-derivatives were least active (1 papilloma per mouse). The chemical reactivities of these compounds were studied by observing the degree of color produced with time on reaction with 4-(p-nitrobenzyl) pyridine. All compounds, except the 6-fluoro derivative, showed a correlation between the tendency to react in chemical assay according to first order kinetics and the ability to initiate papillomas in mouse skin.

- 3672 THE BINDING OF POLYCYCLIC AROMATIC HYDROCARBONS TO THE DNA, RNA, AND PROTEINS OF TRANSFORMABLE CELLS IN CULTURE. (E.) Kuroki, T. (U. Wisconsin Med. Sch., Madison) and C. Heidelberger. *Cancer Res* 31:2168-2176, 1971.

Normal, transformed and revertant lines of C3H mouse prostate and C3H and Syrian hamster embryonic fibroblast cells were incubated with ³H-labeled polycyclic aromatic hydrocarbons (1 µg/ml) and the extent of binding to cellular DNA, RNA and protein fractions was measured. The extent of binding in the embryonic cells was very similar to that previously found with mouse skin *in vivo*. Chemically and spontaneously transformed cells bound five to ten times less hydrocarbon than did the parental non-transformed prostate cells, although less malignant variants obtained from highly malignant clones bound the hydrocarbons to two-thirds the extent of the nontransformed cells. The distribution of bound carcinogen among the three cellular constituents differed markedly for the individual hydrocarbons. Benzo(a)pyrene (BP) bound preferentially to proteins, while 7,12-dimethylbenz(a)anthracene (DMBA) bound primarily to nucleic acids. The weakly carcinogenic dibenz(a,h)anthracene (DBA) showed the second highest affinity for protein. BP and 3-methylcholanthrene bound to RNA with specific activities about one-half that of DMBA, and to DNA with specific activities about one-fourth that of DMBA. In all cells, the extent of binding of the weakly carcinogenic dibenz(a,c)anthracene to all macromolecules was greater than that of the isomeric and more carcinogenic DBA. There was no significant difference in the binding of hydrocarbons to exponentially growing and contact inhibited cells. This binding was stable and persisted up to five wk when there was no cell growth. Approximately 15% of the bound carcinogen was lost during one cell division in replicating cultures.

- 3673 STRUCTURE-ACTIVITY RELATIONSHIPS IN TOXICITY AND CARCINOGENICITY OF AFLATOXINS AND ANALOGS. (E.) Wogan, G. N. (Dept. Nutr. Food Sci., Massachusetts Inst. Technol., Cambridge), G. S. Edwards and P. M. Newberne. *Cancer Res* 31:1936-1942, 1971.

A study was conducted to determine the toxicity and carcinogenicity of a series of aflatoxins and aflatoxin analogs in rats and ducklings. When ad-

ministered as a single dose by gastric intubation, all four aflatoxins (B_1 , G_1 , B_2 and G_2) were lethal to ducklings. Only aflatoxins B_1 and G_1 were lethal under these conditions to rats. Aflatoxins B_2 and G_2 , tetrahydrodeoxy B_1 and three synthetic compounds containing the fused coumarin-cyclopentene systems of the aflatoxin B molecule were all nontoxic at doses 200 times greater than the effective level of aflatoxin B_1 . Aflatoxins B_1 and G_1 induced hepatocellular carcinomas when given intragastrically in high doses to rats. When given intragastrically or by i.p. injection using a multiple dose regimen, aflatoxin B_1 was more carcinogenic than aflatoxin B_2 . In a similar manner, multiple s.c. injections of aflatoxin B_1 induced sarcomas in all animals tested. Aflatoxin B_2 was noncarcinogenic under these conditions. Neither tetrahydrodeoxyaflatoxin B_1 nor any of the three synthetic compounds showed evidence of carcinogenic activity. Collectively, these results indicate that the furofuran moiety of the aflatoxin structure is essential for toxic and carcinogenic activity. Also, the presence of the double bond in the terminal furan ring is an important determinant of potency. Differences in potency of aflatoxins B_1 and G_1 illustrate the importance of the substituents on the lactone portion of the molecule.

- 3674 REACTION OF ALKYLATING MUTAGENS AND CARCINOGENS WITH NUCLEIC ACIDS: N-3 OF GUANINE AS A SITE OF ALKYLATION BY *N*-METHYL-*N*-NITROSOUREA AND DIMETHYL SULPHATE. (E.) Lawley, P. D. (Chester Beatty Res. Inst., Chalfont St. Giles, England), D. J. Orr and S. A. Shah. *Chem Biol Interact* 4:431-434, 1971/72.

The methylation of salmon sperm DNA by S_N2 and S_N1 type alkylating agents (represented by dimethyl sulfate and *N*-methyl-*N*-nitrosourea, resp.) was studied *in vitro* at neutral pH. Methylated bases were isolated from alkylated DNA hydrolysates and were identified by chromatography or UV absorbance spectroscopy using authentic methylated bases as standards. Incubation of salmon sperm DNA with *N*-methyl-*N*-nitrosourea produced a small quantity of 3-methylguanine in addition to 7-methyladenine, 7-methylguanine, 0⁶-methylguanine, 3-methyladenine and 1-methyladenine. Parallel experiments with dimethyl sulfate or methyl methanesulfonate gave similar results, except that an additional peak of 1,7-dimethylguanine was seen and no 0⁶-methylguanine was found. The formation of 3-methylguanine, a potentially miscoding base, provides another possible mechanism for the weakly mutagenic S_N2 alkylating agents.

- 3675 THE *IN VITRO* INTERACTION OF A METABOLITE OF *N*-ACETYL-4-AMINOBIIPHENYL WITH RAT LIVER MITOCHONDRIA. (E.) Hadler, H. I. (Dept. Chem. Biochem., Southern Illinois U., Carbondale) and B. G. Daniel. *Cancer Res* 32(5):1037-1041, 1972.

N-hydroxy-*N*-acetyl-4-aminobiphenyl (N-OH-AABIP) (30-

300 μ M), a metabolite of *N*-acetyl-4-aminobiphenyl, alone or in combination with showdomycin (300 μ M), was studied for its ability to induce an ATP-energized rat mitochondrial volume change by measuring the decrease in absorbance at 520 nm by spectrophotometry. Neither the thiol reagent, showdomycin, nor N-HO-AABIP alone produced a change in mitochondrial volume. N-HO-AABIP (300 μ M) and showdomycin (300 μ M) together induced marked mitochondrial swelling which could be inhibited by the further addition of oligomycin (0.33 μ g/ml). A very modest enhancement in mitochondrial swelling occurred when the pH was raised from 7.4 to 7.8. Mitochondrial volume change was dependent on the concentration of N-HO-AABIP. Showdomycin could be replaced by the classical thiol reagent NEMI (30 μ M). The parent carcinogen, AABIP, either alone or in combination with showdomycin did not induce mitochondrial volume change. Analysis of mitochondrial respiration by oxygen electrode showed that it was inhibited by N-OH-AABIP whether or not respiration had been uncoupled or had been stimulated by the addition of ADP. These results paralleled earlier observations, based on the same assay system, that *N*-hydroxy-*N*-acetyl-2-aminofluorene exposed a mitochondrial thiol group which participated in the process of oxidative phosphorylation while its parent compound did not. The ability to expose this thiol group may be related to the ability of the carcinogen to exert its effect.

- 3676 MECHANISMS OF MESOTHELIOMA INDUCTION WITH ASBESTOS AND FIBROUS GLASS. (E.) Stanton, M. F. (Nat'l. Cancer Inst., Bethesda, Md.) and C. Wrench. *J Nat Cancer Inst* 48(3):797-821, 1972.

In experiments with 1200 rats, samples of asbestos, fibrous glass, silica and metal particles were implanted in pleura of 11-16 wk old rats. Mesothelioma induction was observed over two yr. Of seven forms of asbestos given, amosite at the maximum dose (40 mg) was the first to produce a fatal mesothelioma (after 53 wk). Standard crocidolite, partially pulverized crocidolite, hand-milled and ball-milled crocidolite produced similar mesothelioma incidences (58-75%). A comparison of tumor induction by an excessively milled, partially pulverized crocidolite with submicroscopic fibrils with tumor induction by standard crocidolite showed that the smaller fibrils were associated with a reduced tumor incidence (20-32%). Mesothelioma incidence correlated with the number of glass or asbestos microfibers present in lesions. Nickel-chrome steel particles produced no mesotheliomas. Silica spheres of submicroscopic size induced one mesothelioma in 48 rats. Nickel particles induced two rare tumors, pituitary adenoma and kidney carcinoma. An intact fibrous glass vehicle did not produce tumors. However, when fibrous glass was reduced to short fibrous fragments (mean length = 5 μ , mean diameter = 0.06-3 μ) it caused small but significant numbers of mesotheliomas (eight in 54 rats). It is concluded that the carcinogenicity of asbestos and fibrous glass is related to the structural shape of these materials, and not to their physicochemical properties.

3677 NEOPLASTIC TRANSFORMATION AND CHROMOSOMAL ABERRATIONS INDUCED BY *N*-METHYL-*N'*-NITRO-*N*-NITROSOGUANIDINE IN HAMSTER LUNG CELLS IN TISSUE CULTURE. (E.) Inui, N. (Nat'l. Cancer Ctr. Res. Inst., Tokyo, Japan) and T. Sugimura. *J Nat Cancer Inst* 48(5):1409-1417, 1972.

Cultured hamster lung fibroblasts were treated with 6.8×10^{-5} or 6.8×10^{-6} M *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG) for 24 hr. After removal of MNNG, cells in the group given 6.8×10^{-5} M showed pyknosis of nuclei, cell necrosis and cytoplasmic disintegration. By 27-47 days, disordered arrangements of fusiform cells were seen and transformed foci appeared in which cells piled up to form dense felt-like layers. A criss-cross pattern of cells was seen in transformed cell foci. Transformed cells grew continuously in culture for more than 200 days. MNNG-transformed cells showed changes in chromosome numbers at 167 days after MNNG; modal chromosome numbers showed a variation between 36 and 121. Monosomies and trisomies were also seen in transformed cells. Transformed cells acquired chromosome modes of 46 soon after transformation, and the previous chromosomal changes did not recur. No marker chromosomes were seen in MNNG-transformed cells. Cells transformed by 6.8×10^{-5} M MNNG produced fibrosarcomas in a hamster inoculated with cells 160 days after MNNG transformation. Untreated hamster lung cells and cells given 6.8×10^{-6} M MNNG were not tumorigenic.

3678 THE ROLE OF ARL HYDROCARBON HYDROXYLASE IN 7,12-DIMETHYLBENZ(a)ANTHRACENE SKIN TUMORIGENESIS: ON THE MECHANISM OF 7,8-BENZOFLAVONE INHIBITION OF TUMORIGENESIS. (E.) Kinoshita, N. (Nat'l. Cancer Inst., Bethesda, Md.) and H. V. Gelboin. *Cancer Res* 32:1329-1339, 1972.

Aryl hydrocarbon hydroxylase (AHH) induction by topical application of 100 nmoles each of benz(a)anthracene (BA), 7,12-dimethylbenz(a)anthracene (DMBA) and 7,8-benzoflavone (7,8-BF) was observed in skin homogenates of NIH Swiss mice. BA showed the highest AHH induction; 7,8-BF was not an inducer. 7,8-BF at 10^{-4} M inhibited AHH in skin by 73-88%. Both BA and 7,8-BF inhibited the removal of 14 C-DMBA from mouse skin, indicating that the reported inhibition of DMBA skin tumorigenesis by 7,8-BF did not result from a more rapid rate of removal of the carcinogen from skin. However, 7,8-BF, applied simultaneously with DMBA to mouse skin, caused a diminution of the amount of DMBA bound to DNA, RNA and protein by 71, 52 and 51%, resp. 7,8-BF may, therefore, inhibit DMBA skin tumorigenesis by reducing the amount of carcinogen bound to macromolecules. In tests of tumorigenesis inhibition, mice were painted once with DMBA together with BA or 7,8-BF and followed up with weekly croton oil applications. BA and 7,8-BF inhibited DMBA tumorigenesis by 66 and 80%, resp., at ten wk after DMBA application. By wk 16, suppression of tumorigenesis by 7,8-BF was still in effect, while suppression by BA was no longer evident. 7,8-BF was also a potent inhibitor of

DMBA skin tumorigenesis when the carcinogen was applied repeatedly. 7,8-BF applied 12 hr before or 12 hr after DMBA did not inhibit tumorigenesis. It was concluded that DMBA requires metabolic activation by AHH for its carcinogenic effect. However, the levels of AHH and DMBA tumorigenesis vary in different mouse strains, indicating that DMBA metabolite formation profiles differ in genetically different mice, or that AHH activation is necessary but not sufficient for DMBA tumorigenesis.

3679 THE SHORT-TERM EFFECTS OF 4-NITROQUINOLINE 1-OXIDE ON THE IMMUNE RESPONSE IN MICE. (E.) Phillips, J. M. (Dept. Cancer Studies, U. Birmingham, England). *Int J Cancer* 9(1):39-47, 1972.

(C57BL x IF)₁ mice were given s.c. injections of 4-nitroquinoline 1-oxide (NQO) 24 hr prior to the injection of sheep red blood cells (SRBC). Four days after SRBC, the mice were killed, spleens were removed and antibody-forming cells in the spleen were counted by a hemolytic plaque technique ("localized hemolysis in gel assay"). NQO at 0.5 and 1.0 mg significantly depressed the number of plaque-forming cells (PFC) formed in mouse spleens in response to SRBC. When the non-carcinogenic analogs of NQO, 4-chloroquinoline 1-oxide and 4-nitropyridine 1-oxide, were given to mice in place of NQO 24 hr before SRBC, no effect on PFC response in spleen cells was seen. When NQO was given at various times before and after SRBC, it was found that PFC number in spleen cells was most depressed when NQO was given two days after SRBC. To determine whether NQO-induced immunodepression resulted from NQO acting specifically on bone marrow-derived or thymus-derived cells, normal bone marrow and thymus cells were injected along with spleen cells from NQO-treated mice into irradiated recipients. The results indicated that bone marrow cells were most affected by NQO, thymus cells remaining unaffected. No depression of cell-mediated immunity by NQO was found in tests of skin allograft rejection or in graft-versus-host reactions in NQO-treated mice. Furthermore, NQO did not appear to alter the time of appearance of 19S or 7S antibody response in mice, indicating that NQO-induced immunodepression was not caused by a delay in antibody production.

3680 ON THE PERSISTENCE OF TUMOUR INITIATION AND THE ACCELERATION OF TUMOUR PROGRESSION IN MOUSE SKIN TUMORIGENESIS. (E.) Roe, F. J. C. (Chester Beatty Res. Inst., London, England), R. L. Carter, B. C. V. Mitchley, R. Peto and E. Hecker. *Int J Cancer* 9(2):264-273, 1972.

The hypothesis that the effects of tumor initiation by 7,12-dimethylbenz(a)anthracene (DMBA) applied to mouse skin persist unchanged for long periods was tested using 12-O-tetradecanoyl-phorbol-13-acetate (TPA) as a tumor promoting agent. Urethane was administered i.p. to see if it favored development of malignant skin tumors in mice bearing benign

tumors as a result of treatment with DMBA and TPA. Female Swiss mice exposed twice weekly to 3.125 µg TPA for 15 weeks developed multiple papillomas when treatment was started three weeks after tumor initiation with 100 µg DMBA, but very few when the interval was 50 weeks. All tumors developing up to 20 weeks after treatment with DMBA and/or TPA were benign. Administration of urethane i.p. increased the risk of malignant skin tumor development in mice previously exposed to DMBA and TPA as compared with i.p. injections of distilled water. The possibility that the effect of urethane on the incidence of malignant tumor was related to its general toxicity rather than to its carcinogenicity is discussed.

- 3681 PROLIFERATIVE ENDOMETRIAL RESPONSE TO THECA-GRANULOSA CELL TUMORS. (E.) Gusberg, S. B. (Mount Sinai Sch. Med., New York, N.Y.) and P. Kardon. *Trans Amer Gynec Soc* 94:184-194, 1971.

A total of 115 patients with thecoma, granulosa cell tumor or theca-granulosa cell tumor of the ovary were examined for carcinoma or its precursors in the endometrium. It was assumed that the endometria of patients with feminizing ovarian tumors such as theca-granulosa cell tumors would be subject to continuous endogenous estrogen stimulation. It was found that 64.3% of patients harbored endometria with proliferative changes more advanced in malignant potential than cystic glandular hyperplasia. Adenocarcinoma was seen in 21% of patients, carcinoma *in situ* in 4.3% and adenomatous hyperplasia in 39%. The prevalence of cancer and its precursors was 46.75% in premenopausal patients and 70.8% in postmenopausal patients.

- 3682 γ-GLUTAMYL TRANSPEPTIDASE IN TRANSPLANTABLE, CHEMICALLY INDUCED RAT HEPATOMAS AND "SPONTANEOUS" MOUSE HEPATOMAS. (E.) Fiala, S. (VA Hosp., San Fernando, Calif.), A. E. Fiala and B. Dixon. *J Nat Cancer Inst* 48(5):1393-1401, 1972.

Four transplantable rat hepatomas, induced by chemical carcinogens including 3'-methyl-4-dimethylaminoazobenzene and N-2-fluorenylacetamide, were homogenized, centrifuged and subjected to polarographic and colorimetric assays for γ-glutamyl transpeptidase (glutathionase). The assays measured cysteinylglycine and L-cysteine, which are produced by glutathionase. High levels of glutathionase were seen in all hepatomas, but not in normal adult rat liver. Hepatoma extracts incubated for 60 min showed higher amounts of L-cysteine than unincubated extracts, indicating that L-cysteine was liberated by enzyme from some maternal compound. Glutathionase levels in fetal and normal neonatal rat liver were comparable to levels in hepatomas. The distribution of glutathionase among hepatoma fractions was as follows: 28% in nuclei; 27% in mitochondria; 45% in microsomes. Supernatants had no enzyme activity. Glutathionase activity was high in neonatal C3H x Y mouse liver and low in adult mouse and rat liver. Three of four spontaneous mouse hepatomas, however,

showed low enzyme levels comparable to levels in normal adult mouse and rat livers.

- 3683 THE FORMATION OF VARIANTS WITH A REVERSION OF PROPERTIES OF TRANSFORMED CELLS: VII. CHROMOSOME NUMBERS AND RE-REVERSION IN SUBTETRAPLOID VARIANTS. (E.) Hitotsumachi, S. (Weizmann Inst. Sci., Rehoveth, Israel), R. Schaki, B. Padeh, Z. Rabinowitz and L. Sachs. *Int J Cancer* 10:9-13, 1972.

Three variants, 1-1, 2T-1 and 3T-1, isolated from hamster cells transformed by polyoma virus were studied for saturation density, cloning efficiency in soft agar and liquid medium, percent of colonies formed at 41°C and tumorigenicity after s.c. inoculation into adult hamsters. Variant 1-1 was isolated from hamster embryo cells transformed *in vitro* by virus, while 2T-1 and 3T-1 were obtained from polyoma virus-induced tumors. The three variants were studied at three and 33 wk after clone isolation. At three wk, variant 1-1 showed reversion of both *in vitro* properties of transformed cells and reversion of ability to produce tumors. At 33 wk after isolation, 1-1 showed a considerable degree of reversion of the *in vitro* transformed properties and of ability to produce tumors. Reversion of tumorigenicity was not as complete in 2T-1 and 3T-1 variants at three wk after isolation as it was in 1-1 cells. Both variants 2T-1 and 3T-1, however, showed a considerable degree of re-reversion between three and 33 wk after isolation. All three variants were subtetraploid initially, and all three showed an increase in chromosome numbers between three and 33 wk after clone isolation.

- 3684 RECONSTITUTED TOBACCO--SMOKING AND HEALTH POSSIBILITIES. (E.) Halter, H. M. (AMF Inc., Richmond, Va.) and T. I. Ito. *J Nat Cancer Inst* 48(6):1869-1883, 1972.

Tumor initiation and promotion experiments were performed on the skin of female Ha/ICR mice using tars from machine-smoked cigarettes made of natural tobacco or of reconstituted tobacco sheet. In initiation experiments, mice were painted topically with tar from natural tobacco and reconstituted tobacco cigarettes; in promotion experiments, tar painting followed tumor induction by 7,12-dimethylbenz(a)-anthracene. Tars from reconstituted sheets produced fewer tumors than tar from natural tobacco cigarettes. Reconstituted tobacco tar and natural tobacco tar did not differ significantly as tumor promoters. Tar from reconstituted tobacco sheets processed using a nonaqueous solvent produced fewer tumors than either natural tobacco tar or tar from reconstituted sheet tobacco processed with an aqueous solvent. The nonaqueous solvent sheet tobacco tar, however, was a better tumor promoter than natural tobacco tar. Tar from special low-density reconstituted tobacco sheets produced fewer tumors, and was a poorer tumor promoter, than natural tobacco tar. Studies performed at the Cigarette Institute of Hamburg, Germany, indicate that some reconstituted

tobacco sheet types are superior to others in reducing tumorigenicity of tobacco tar.

- 3685 HISTOGENESIS OF SQUAMOUS METAPLASIA IN THE HAMSTER TRACHEAL EPITHELIUM CAUSED BY VITAMIN A DEFICIENCY OR BENZO(a)PYRENE-FERRIC OXIDE. (E.) Harris, C. C. (Nat'l. Cancer Inst., Bethesda, Md.), M. B. Sporn, D. G. Kaufman, J. M. Smith, F. E. Jackson and U. Saffiotti. *J Nat Cancer Inst* 48(3):743-761, 1972.

Male hamsters were given intratracheal instillations of 5 mg benzo(a)pyrene (BP) with ferric oxide as a carrier dust; another group of hamsters was maintained on a vitamin A-deficient diet. The development of metaplastic lesions in tracheas was observed. BP and ferric oxide and vitamin A deficiency caused similar squamous metaplastic lesions without cellular atypism in tracheal epithelium. In vitamin A-deficient hamsters, squamous cells developed from basal cells. In animals given BP and ferric oxide, epithelial hyperplasia appeared as squamous metaplasia with or without cellular atypism. Differentiated ciliated and mucous cells were replaced by pleomorphic cells. BP and ferric oxide, but not vitamin A deficiency, were associated with enlarged nucleoli, discontinuous basement membranes and electron-dense granules in neoplastic cells.

- 3686 EFFECTS OF PYRAN COPOLYMER ON ONCOGENIC VIRUS INFECTIONS IN IMMUNOSUPPRESSED HOSTS. (E.) Hirsch, M. S. (Harvard Med. Sch., Boston, Mass.), P. H. Black, M. L. Wood and A. P. Monaco. *J Immunol* 108(5):1312-1318, 1972.

Female CBA mice were immunosuppressed by thymectomy, injected with antilymphocyte serum, inoculated with pyran copolymer (125 mg/kg) and inoculated with polyoma virus preparation (2.5×10^6 TCID₅₀). Controls were immunosuppressed and virus-inoculated, but were not given pyran. By 470 days after virus, tumors, including sarcomas and adenocarcinomas, had developed in sites including breasts, parotid glands and bones of 19 of 21 immunosuppressed mice given virus but not pyran. Only two of 21 immunosuppressed and pyran-treated mice developed tumors by day 470. In other experiments, C3H/HeJ and A/He mice were immunosuppressed as above and given pyran (25 mg/kg) before inoculation with Rauscher leukemia virus. Controls were as above. Pyran prevented the development of Rauscher virus-induced erythroblastic splenomegaly. By two yr after virus, erythroblastic leukemia had developed in all of 68 mice infected with virus and immunosuppressed but not given pyran. Only three of seven pyran-treated mice had developed leukemia. The mechanisms of protection by pyran appeared to be secondary to macrophage activation and enhanced phagocytosis.

- 3687 TUMOR PROMOTERS IN TOBACCO AND CIGARETTE-SMOKE CONDENSATE. (E.) Bock, F. G. (Roswell Park Mem. Inst., Buffalo, N. Y.). *J Nat Cancer Inst* 48(6):1849-1853, 1972.

Studies on topical tumor initiation and promotion on mouse skin by fractions of extracts of unburned tobacco (TE) and cigarette smoke condensate (CSC) are reported. In tumor promotion experiments, mice were painted with 7,12-dimethylbenz(a)anthracene before painting with test tumor promoters. Crude TE contained at least two agents which acted together to promote tumorigenesis. One TE fraction of low molecular wt (<1200) was soluble in water, methanol and 1:1 methanol-benzene. Another, high molecular wt TE fraction (>1200) was water soluble but was not soluble in methanol. The high molecular wt TE fraction, being insoluble in organic solvents, probably could not persist in tobacco smoke. The low molecular wt TE fraction may persist in tobacco smoke. CSC contained at least five fractions exhibiting tumor-promoting activity, including the weakly polar materials fraction (WPN) containing polynuclear aromatic hydrocarbons, the weak acids fraction (WA) and the most polar neutral materials fraction (MPN). The WPN fraction was a complete carcinogen; the WA and MPN fractions were only tumor promoters. The remaining two fractions were not adequately tested for complete carcinogenic activity. The WA and WPN fractions were strongly synergistic as promoters. MPN, although active alone, did not add to the tumor-promoting activity of WA or WPN, or the two combined.

- 3688 EARLY STAGE IN THE METABOLISM OF AMINOAZO DYES IN THE LIVER OF RATS. (E.) Du Plooy, M. (South African Coun. Sci. Indust. Res., Pretoria) and J. Dijkstra. *Chem-Biol Interact* 4(3):163-173, 1971/72.

Male rats were given 25 mg *N,N*-dimethylaminoazobenzene (DAB)/100 g body wt by stomach tube and were also dosed with ³⁵S-methionine and ³⁵S-sulphate. The rats were killed after DAB administration and their livers were homogenized and the homogenates centrifuged. Early metabolites of DAB in liver were separated from unchanged DAB by thin-layer chromatography of centrifuge supernatants. The maximum concentration of early metabolites of DAB was found four hr after dosing with DAB. These metabolites had the same properties as the "early metabolites" of 3'-methyl-*N,N*-dimethylaminoazobenzene in that 75% of the dye extractable with trichloroacetic acid (TCA) was not soluble in ethyl ether. Dyes could also be extracted from liver by ethanol. The ethanol extract of DAB-dosed liver was fractionated into six components by paper electrophoresis. Ninety percent of TCA-soluble metabolites of DAB could be accounted for as the ethereal sulfates of 4'-hydroxy-*N*-monomethylaminoazobenzene and 4'-hydroxy-*N*-acetylaminoazobenzene. Besides these two major components, four minor components in the early metabolites of DAB were also sulphated.

- 3689 INHIBITION OF CARCINOGENIC AND TOXIC EFFECTS OF POLYCYCLIC HYDROCARBONS BY PHENOLIC ANTI-OXIDANTS AND ETHOXYQUIN. (E.) Wattenberg, L. W. (U. Minnesota Med. Sch., Minneapolis). *J Nat Cancer Inst* 48(5):1425-1430, 1972.

Female Ha/ICR mice were fed benzo(a) pyrene or 7,12-dimethylbenz(a)anthracene (DMBA) together with the antioxidants butylated hydroxyanisole (BHA), butylated hydroxytoluene (BHT), ethoxyquin or alpha-tocopherol. The development of tumors of the forestomach was observed. BHA, BHT and ethoxyquin decreased the number of mice with tumors and the number of tumors/mouse. Alpha-tocopherol had no significant effect on tumorigenesis. BHA also decreased the lethality of dietary DMBA (0.2 mg daily for 28 or 35 days). In related experiments, DMBA was given by oral intubation to female Sprague-Dawley rats pretreated with test antioxidants, and the production of mammary tumors was observed. Eighty percent of rats given DMBA but no antioxidant developed mammary tumors; in rats given BHA, BHT or ethoxyquin, tumor incidence was 39, 28 and 12%, resp. Alpha-tocopherol did not significantly depress DMBA mammary tumorigenesis. Ha/ICR mice were also treated topically with antioxidants and later with DMBA at the same site. Only BHA at high doses inhibited DMBA epidermal tumorigenesis, and the inhibition by BHA was not statistically significant. BHA, BHT and ethoxyquin, but not alpha-tocopherol, prevented adrenal necrosis in rats given 30 mg DMBA by oral intubation.

3690 ASCORBATE-NITRITE REACTION: POSSIBLE MEANS OF BLOCKING THE FORMATION OF CARCINOGENIC N-NITROSO COMPOUNDS. (E.) Mirvish, S. S. (Eppler Inst. Res. Cancer, Omaha, Nebr.), L. Wallcave, M. Eagen and P. Shubik. *Science* 177(4043):65-68, 1972.

Oxytetracycline, morpholine, piperazine, *N*-methylaniline, methylurea or dimethylamine were reacted with nitrous acid, and the formation of carcinogenic *N*-nitroso compounds (e.g., dimethylnitrosamine) by the nitrosation of the various compounds was observed in the presence or absence of ascorbic acid. Nitrosation of morpholine and piperazine was blocked by more than 98% by ascorbic acid. Blocking by ascorbic acid was only partial for *N*-methylaniline, but was fairly complete for methylurea and oxytetracycline. Ascorbic acid blocked nitrosation of dimethylamine at pH 3 and 4, but at pH 2 there was little effect, and at pH 1 ascorbic acid enhanced nitrosation. Urea was less effective as a blocking agent than ascorbic acid. Ammonium sulfamate was more effective than ascorbic acid at pH 1 and 2, but was relatively ineffective at pH 3 and 4. Ascorbic acid, it was concluded, might inhibit formation of carcinogenic *N*-nitroso compounds *in vivo*.

3691 LEUKEMIA INDUCED BY 7,8,12-TRIMETHYLBENZ(a)-ANTHRACENE IN RATS. II. CHANGES IN BONE MARROW. (E.) Bird, C. (Ben May Lab. Cancer Res., U. Chicago, Illinois). *J Nat Cancer Inst* 48(2):429-439, 1972.

Pulse doses of a 0.5% lipid emulsion of 7,8,12-trimethylbenz(a)anthracene (TMBA) were injected i.v. at 10-day intervals into random-bred male L-E rats. After initial severe hypoplasia of bone marrow, leukemia developed in high numbers, with involve-

ment of bone marrow, liver, spleen, lymph nodes and adrenal glands. The thymus, however, was rarely implicated. A characteristic osteopathy developed in leukemic rats. In long bones, bone marrow adjacent to the metaphysis was sclerosed and often contained irregular trabeculae of new woven bone, whereas the cortex of the shaft was usually thickened. After repeated TMBA treatment, the "physiological anemia" of weanling rats failed to regress, and this was ascribed to the severe reduction of erythropoiesis in the hypoplastic bone marrow. Alkaline and acid phosphatase, lactate dehydrogenase (LDH) and malate dehydrogenase (MDH) activities were determined by spectrophotometric techniques in bone marrow homogenates of control and leukemic rats. In bone marrow of normal rats, activity of LDH was 1.55 ± 0.29 times that of MDH. In leukemic rats, a significant increase in activity ($28 \pm 11\%$) was observed only in the case of LDH; MDH activity was unchanged. Both acid and alkaline phosphatase activity was increased slightly in leukemic rats, compared with controls; however, the relative proportion of activities was unchanged. In hypoplastic bone marrow, LDH and acid phosphatase activities were significantly reduced, but reduction in alkaline phosphatase activity was associated only with the most severe grades of marrow hypoplasia.

3692 HYDRAZINE, METHYLHYDRAZINE AND METHYLHYDRAZINE SULFATE CARCINOGENESIS IN SWISS MICE: FAILURE OF AMMONIUM HYDROXIDE TO INTERFERE IN THE DEVELOPMENT OF TUMORS. (E.) Toth, B. (U. Nebraska Coll. Med., Omaha). *Int J Cancer* 9(1):109-118, 1972.

Randomly bred Swiss mice were given hydrazine (H, 0.001% solution), methylhydrazine (MH, 0.01%), methylhydrazine sulfate (MHS, 0.001%) or ammonium hydroxide (AH, 0.3, 0.2 or 0.1%) in drinking water for life. In addition, C3H mice were given AH (0.1%) in drinking water for life. Tumor development was observed. Lung tumors developed in 54% of 27 females and in 48% of 24 males in mice given H. This represented a significant increase over tumor incidence in mice not given H. Malignant lymphomas and breast tumors were also seen in H-treated mice. Forty-six percent of 23 females and 46% of 23 males given MHS developed lung tumors, also a significant increase in lung tumor incidence for the MHS-treated group. Lung tumor incidence in female and male MH-treated mice was 24% and 22% resp. MH evidently enhanced the development of lung tumors by shortening their latent period in treated mice. AH in Swiss and C3H mice was without carcinogenic effect. However, 60% of C3H mice given AH developed breast tumors, indicating that AH does not inhibit the development of breast tumors which are characteristic of that strain.

3693 EFFECT OF SMOKING ON THE SURVIVAL OF PATIENTS WITH LUNG CANCER. (E.) Linden G. (California State Dept. Public Hlth.), J. E. Dunn, Jr., P. H. Hom and M. Mann. *Cancer* 30(2):325-328, 1972.

The histories of 460 male patients with lung cancer, on whom smoking information had been obtained prior to diagnosis of the disease, were studied to determine whether or not a relationship exists between cigarette smoking and length of survival. No significant differences in the survival rates among patients in the various smoking categories were observed and the stage of the disease at the time of diagnosis was found to be the main factor in determining the length of survival. Patients who smoked two or more packs of cigarettes per day had the largest percentage of squamous cell carcinomas, the highest percentage of localized cases (22%) and the best survival. The latter two findings either could be due to the fact that squamous cell carcinoma has a lower metastatic potential than adenocarcinoma, which was more prevalent in lighter smokers, or could be because the presence of respiratory symptoms caused the heavy smokers to seek medical care earlier.

- 3694 TUMORIGENICITY AND AGGLUTINATION BY CONCAVALIN A OF CHINESE HAMSTER CELLS AND THEIR HYBRIDS. (E.) De Micco, Ph. (Res. Unit I.N.S.E.R.M., Marseilles, France) and M. Berebbi. *Int J Cancer* 10(2):249-253, 1972.

The agglutinability of two Chinese hamster cell strains differing in tumorigenic ability was studied *in vitro* with concanavalin A. The DC-3F strain, which produced tumors in 100% of animals following inoculation into the cheek pouch, showed a high degree of agglutinability. The nontumorigenic DC-3F/ADX/Aza strain had a low degree of agglutinability. A hybrid strain, HyC, obtained by fusion of these two lines, was 78% tumorigenic and showed a degree of agglutinability which was intermediate between those of the DC-3F and DC-3F/ADX/Aza strains. A number of sublines cloned from the HyC hybrid line exhibited agglutinabilities which increased in relation to their tumorigenicity. Tumors resulting from inoculation to these clonal lines into hamster cheek pouches showed agglutinabilities which were, in general, much higher than those of the inocula.

- 3695 ULTRASTRUCTURAL CHANGES IN NUCLEI AND NUCLEOLI OF RAT LIVER CELLS TREATED WITH HEPATOCARCINOGENS. (E.) Sugihara, R. (Nara Med. U., Japan), Y. Hiasa and N. Ito. *Gann* 63(4):419-426, 1972.

Male Wistar rats were fed a diet containing 0.12% 3'-methyl-4-(dimethylamino)azobenzene, 0.05% N-2-fluorenylacetamide, or 0.5% DL-ethionine. The liver nodules and carcinomas which developed were studied by electron microscopy and their ultrastructures were compared with that of normal liver tissue from controls. Tumors developing from all three carcinogens were histologically similar. The cells of the hepatic cell carcinomas could be classified into three groups based on their nuclear structure: (1) cells with a structure similar to that of hyper-

plastic nodular cells, (2) cells with an intermediate structure, and (3) cells with the typical characteristics of cancer cells. The carcinoma cells which resembled nodular cells seemed to be derived from the nodular cells. These hepatocarcinoma cells contained small chromatin particles on the inner layer of the nuclear envelope (perinuclear chromatin) and in the peripheral part of the nucleolus (nucleolus-associated chromatin), in contrast to nodular cell nuclei in which all the chromatin fibrils were loose and dispersed in the nucleoplasm. The nodular-type carcinoma cells had round nucleoli with reticular nucleolonemas in contrast to nodular cells in which the nucleolonemas were deformed and contained an increased quantity of granular material.

- 3696 EXPERIMENTAL CANCER OF THE LUNG IN RABBITS INDUCED BY CHEMICAL CARCINOGENS. (E.) Hirao, F. (Osaka U. Med. Sch., Japan), T. Fujisawa, E. Tsubura and Y. Yamamura. *Cancer Res* 32(6):1209-1217, 1972.

The carcinogenic activities of 3-methylcholanthrene (MCA) and 4-nitroquinoline 1-oxide (NQO) were studied in male and female 50- and 100-day-old rabbits. In the first experiment, one group of animals received intrabronchial instillations every seven to ten days of a mixture of 40 mg MCA and 0.4 mg NQO suspended in rabbit plasma. The second group of rabbits received intrabronchial instillations of 40 mg MCA alone in distilled water. Altogether, lung cancer was induced in 80 of 173 rabbits that received more than four doses of carcinogens and survived for more than 30 days. Half were squamous cell carcinoma and one-quarter were adenocarcinoma. The remainder consisted of mixed squamous cell and adenocarcinoma, pleomorphic carcinoma, undifferentiated cell carcinoma and sarcoma. Metastases to other organs (paratracheal lymph nodes, kidneys, mediastinum and chest wall, diaphragm and collateral lung) occurred in 55 cases. The total doses of carcinogens required for 50% incidence of lung cancer were 1000 ± 100 mg MCA and 10 ± 1 mg NQO in group one, and 1330 ± 100 mg MCA in group two. In a second experiment, the superficial bronchial mucosa of adult rabbits was swabbed every one or two days with a solution of 10% MCA in Tween 60. Only two of the 65 rabbits that survived for over 60 days developed lung cancer. One was a pleomorphic and the other a poorly differentiated squamous cell carcinoma.

- 3697 THE INDUCTION OF ATP ENERGIZED MITOCHONDRIAL VOLUME CHANGES BY SHOWDOMYCIN WHEN COMBINED WITH 4',8'-DIHYDROXY-1,2,5,6-DIBENZ-9,10-ANTHRAQUINONE, A METABOLITE OF THE CARCINOGENIC POLYNUCLEAR HYDROCARBON DIBENZ(A,H) ANTHRACENE. (E.) Hadler, H. I. (Dept. Chem., Southern Illinois U., Carbondale), B. G. Daniel, J. Demetrius and R. C. Pratt. *J Antibiot* 24(12):835-845, 1971.

4',8'-dihydroxy-1,2,5,6-dibenz-9,10-anthraquinone

(DI-OH-DBAQ), and hydroxy quinone metabolite of dibenz(a,h)anthracene (DBA), was added to reaction mixtures containing mitochondrial protein prepared from rat liver; in some cases, showdomycin and/or DBA itself were included in reaction mixtures. ATP-energized mitochondrial volume changes were observed. Neither 3 μ M DI-OH-DBAQ nor 300 μ M showdomycin by themselves induced ATP-energized mitochondrial volume changes. However, DI-OH-DBAQ combined with showdomycin did induce an ATP-energized mitochondrial volume change. Oligomycin inhibited the effect induced by the two agents. The volume change induced by 300 μ M showdomycin was enhanced when the concentration of DI-OH-DBAQ was increased from 600 nM to 6 μ M. DBA (6 μ M) failed to induce an ATP-energized mitochondrial volume change when combined with showdomycin. The gramicidin-induced ATP-energized mitochondrial volume changes was progressively inhibited by increasing concentrations of DI-OH-DBAQ. The inhibition of the gramicidin system by DI-OH-DBAQ was relieved by further addition of showdomycin.

- 3698 STATISTICAL ANALYSIS OF THE BIOASSAY OF CONTINUOUS CARCINOGENS. (E.) Peto, R. (Regius Dept. Med., Oxford U., England), P. N. Lee and W. S. Paige. *Brit J Cancer* 26(4):258-261, 1972.

In an experiment consisting of the continuous application of various carcinogenic regimens to a pure strain of experimental animals for a long period, the cancer incidence rates so caused may be studied and compared by the fit of an appropriate class of statistical distributions. Two main families of distributions have appeared in the literature: the lognormal and the Weibull. Of these two, the Weibull distribution, which assumes a "latent period" for tumor development following application of carcinogen and which predicts that the age-specific cancer incidence rate rises as a power of time since first risk, is preferred. The Weibull distribution is suggested by human cancer incidence patterns and is predicted by most theoretical carcinogenesis models. The lognormal distribution is not physically plausible since it has a very eccentric hazard function. The rate-determining parameter for the Weibull distribution is much easier to compute than that for the lognormal distribution. Finally, the rate-determining parameter for the Weibull distribution depends only on the type and dose of carcinogen used and not on the administration regimen.

- 3699 THE CARCINOGENICITY OF TWO DIAZADIBENZOPYRENES. (E.) Zajdela, F. (Radium Inst., Orsay, France), N. P. Buu-Hoi, P. Jacquignon and M. Dufour. *Brit J Cancer* 26(4):262-264, 1972.

1,12-Diazadibenzo(a,i)pyrene (I), 4,11-diazadibenzo(a,h)pyrene (II), and 4,12-diazadibenzo(g,p)chrysene (III) were tested for carcinogenicity by s.c. injection into Swiss mice once a month for three months. The diaza counterpart (I) of dibenzo(a,i)pyrene was

considerably less active than its parent compound, yielding a 39% tumor incidence with a mean latency period of 154 days. However, the diaza counterpart (II) of dibenzo(a,h)pyrene was as active as the parent compound, producing a 93% tumor incidence with a latency period of 175 days. These results indicate that the introduction of two nitrogen atoms into the skeleton of carcinogenic dibenzopyrenes does not suppress their tumorigenic potency as long as the two K-regions remain intact. In contrast, compound III, which was devoid of meso-phenanthrenic region, had no carcinogenic activity.

- 3700 EXPERIMENTAL NEURINOMA IN TISSUE CULTURE. (E.) Cravioto, H. (New York U. Sch. Med. N.Y.), L. Palekar, E. Weiss and K. Bennett. *Acta Neuropath* 21:154-164, 1972.

Fifteen malignant peripheral nerve tumors produced in the offspring of pregnant inbred BD-IX and random-bred CGE rats that received a single i.v. injection of ethylnitrosourea (20 mg/kg body wt) were cultured *in vitro* and were studied with phase contrast optics including time-lapse cinematography. Three cell types were observed in cultures grown in Rose chambers. The most common type was spindle-shaped with a prominent nucleus and nucleolus and slender tapering cell processes. This type most closely resembled Schwann cells and it was therefore concluded that the experimental tumors were Schwann cell tumors. The second cell type was pyramidal-shaped. These cells had a prominent nucleus and exhibited a much lower mitotic activity than the spindle-shaped cells. The third cell type, which was kite-shaped (fibroblast), had the lowest mitotic rate. The predominant cell type in long term cultures maintained in plastic flasks was polygonal-shaped. These cells were subcultured and eventually became established lines. Transplantation of such cells into isologous hosts produced tumors which were similar in structure to the original tumors from which the cultures were established.

- 3701 INDUCTION OF HEMANGIOMATOUS LESIONS WITH DIMETHYLNITROSOAMINE: INFLUENCE OF ROUTE OF ADMINISTRATION AND STRAIN OF MICE. (E.) Kuwahara, A. (Sch. Med., Tokushima U., Japan), H. Otsuka and A. Nagamatsu. *Gann* 63(4):499-502, 1972.

A study was conducted to determine the incidence and localization of benign and malignant hemangiomatous tumors in male and female adult DDD, BALB/c, and SJL/J mice after administration of dimethylnitrosamine (DMN) by different routes. Animals received weekly s.c. or i.p. injections of 0.15 mg DMN or received 100 ppm DMN in the diet. Animals receiving s.c. or i.p. DMN injections showed an equally high incidence (64%) of hemangiomatous lesions which were mainly located in retroperitoneal soft tissue and in abdominal adipose tissue. Of the 91 tumors, 75 were diagnosed as hemangioendothelial sarcomas. The incidence of hemangiomatous tumors was 22.5% in

animals which received DMN orally. The incidence and distribution of the tumors did not for the most part depend on the strain of mouse. Hemangio-matous liver lesions developed most frequently in animals which received s.c. DMN, followed in order by oral and i.p. DMN administration. The few animals which developed spleen and kidney tumors were all DDD strain. A high incidence of epithelial adenomas and carcinomas of the lung was found in all groups irrespective of strain or route of administration. The incidence of soft tissue sarcomas was slightly higher after s.c. than after i.p. injection of DMN.

the tumors and the re-established cell lines contained virus-specific murine leukemia virus CF antigens, and electron microscopy revealed the presence of large numbers of C-type particles.

3704 CARCINOGENIC NITROSAMINES FORMED BY DRUG/NITRITE INTERACTIONS. (E.) Lijinsky, W. (Eppley Inst. Cancer Res., Omaha, Neb.), E. Conrad and R. Van de Bogart. *Nature* 239(5368): 165-167, 1972.

The formation of nitrosamine products, under varying conditions, from the interaction of nitrite with six tertiary nitrogen compounds was studied. Reactions were carried out *in vitro* for four hr at 37 C pH3.5-5.5. The nitrosamine products were extracted and identified by mass spectrometry or infrared spectrometry. All compounds tested gave measurable yields of nitrosamines. Two of the tertiary amines, oxytetracycline and aminopyrene, gave high yields of dimethylnitrosamine (DMN). The production of DMN from aminopyrene occurred over a wide range of pH with no dependence on nitrite concentration, whereas DMN production from oxytetracycline showed a marked dependence on pH (optimum at pH3) and nitrite concentration (maximum at low molar ratios). The dialkylamides (nikethamide, piperline and disulphiram) gave lower yields of diethylnitrosamine and nitrosopiperidine than did the two tertiary amines. These reactions were optimal at pH3. Tolazamide (a substituted urea and dialkylhydrazine) was rapidly converted to the potent liver carcinogen N-nitrosohexamethyleneimine.

3702 INTRANUCLEAR DISTRIBUTION OF THE INDUCING METAL IN PRIMARY RHABDOMYOSARCOMATA INDUCED IN THE RAT BY NICKEL, COBALT AND CADMIUM. (E.) Webb, M. (Strangeways Res. Lab., Cambridge, England), J. C. Heath and T. Hopkins. *Brit J Cancer* 26(4):274-278, 1972.

The binding of metal ions to subcellular fractions of rhabdomyosarcomas induced in rats by i.m. implantation of powdered metallic nickel, cobalt and cadmium was studied. The cell-bound cations were identified by atomic absorption spectrophotometry. Of the total amount of metal recovered in all fractions, 53% of the Ni^{++} , 52% of the Co^{++} and 72% of the Cd^{++} were recovered in the nucleoli. The remainder of each cation was distributed approximately equally between the chromatin and nuclear sap. Most of the nucleolus-associated metal ion, in each case, was bound to RNA.

3703 TRANSFORMATION OF MOUSE CELLS INFECTED WITH AKR LEUKAEMIA VIRUS INDUCED BY SMOG EXTRACTS. (E.) Rhim, J. S. (Microbiol. Assoc., Bethesda, Md.), H. Y. Cho, L. Rabstein, R. J. Gordon, R. J. Bryan, M. B. Gardner and R. J. Huebner. *Nature* 239(5367):103-107, 1972.

Three samples of city smog extracts collected at a location in central Los Angeles were studied for their ability to transform AKR leukemia virus-infected and uninfected mouse embryo (NIH-ME) cells *in vitro*. Chromatographic and UV spectrometric analysis revealed the presence of benz(a)-anthracene and chrysene in each of the extracts. Cell cultures were exposed for seven days to different concentrations of the smog extracts after which time they were subcultured into medium extract. After 14 to 21 days, the AKR leukemia virus-infected cells were transformed by smog concentrations up to 10 μ g/ml. Higher concentrations were lethal. After four subcultures, the transformed cells completely replaced the original fibroblast-like monolayers and were established as continuous lines. Either smog extract-treated uninfected cells nor untreated infected cells showed signs of transformation. S.c. inoculation of cells from two of the transformed lines produced sarcomas at the inoculation site in NIH Swiss mice, with an average latent period of five days. Cells from some of the sarcomas were re-established in tissue culture. Both

3705 MODIFICATION OF RIBONUCLEIC ACID BY CHEMICAL CARCINOGENS. IV. CIRCULAR DICHROISM AND PROTON MAGNETIC RESONANCE STUDIES OF OLIGONUCLEOTIDES MODIFIED WITH N-2-ACETYLAMINOFLUORENE. (E.) Nelson, J. H. (Coll. Physicians Surg., Columbia U., New York, N.Y.), D. Grunberger, C. R. Cantor and I. B. Weinstein. *J Mol Biol* 62(2):331-346, 1971.

Circular dichroism (CD), proton magnetic resonance (PMR) spectroscopy and computer generated molecular models were used to analyze N-2-acetylaminofluorene (AAF)-induced conformational changes of various synthetic mono- and oligonucleotides. Specific covalent attachment of AAF to the C-8 position of guanosine residues resulted in the appearance of a relatively intense negative band at 229 nm as determined by CD spectroscopy. This band was attributed to optical activity introduced into fluorene by its covalent linkage to guanosine. CD spectra were also changed by introduction of AAF into the guanosine residues of A-G, G-A, U-G and G-U. The changes suggested that AAF was possibly also interacting with the dinucleotide constituents other than guanosine. CD analysis of the interaction of AAF with trinucleotides indicated that, in some cases, bases two-removed from guanosine could influence AAF-guanosine interaction. Results obtained from proton magnetic resonance spectroscopic analysis of AAF-oligonucleotide interaction supported those from CD spectroscopy, suggesting

rotation of guanine around the glycosidic linkage and intramolecular stacking of fluorene with the adjacent base. Computer analysis based on the spectroscopic results indicated that severe steric hindrance between AAF and ribose would occur unless guanosine changed its orientation with respect to the glycosidic bond. It was suggested that similar conformational changes may result at localized sites of AAF binding to naturally occurring nucleic acids.

- 3706 UPTAKE OF $^{63}\text{Ni}^{2+}$ FROM ITS COMPLEXES WITH PROTEINS AND OTHER LIGANDS BY MOUSE DERMAL FIBROBLASTS *IN VITRO*. (E.) Webb, M. (Strangeways Res. Lab., Cambridge, England) and S. M. Weinzierl. *Brit J Cancer* 26(4):292-298, 1972.

Incubation of Ni^{2+} with horse serum or rat muscle homogenate results in binding of the metal to both large (proteins) and small (diffusable) molecular wt compounds. The uptake of $^{63}\text{Ni}^{2+}$ from these complexes into the C57S/IP line of mouse dermal fibroblasts was studied. Autoradiographic analysis showed that stationary cells incorporated $^{63}\text{Ni}^{2+}$ and that they did not concentrate the cation at any particular site. Fractionation of cells grown in medium containing the $^{63}\text{Ni}^{2+}$ complexes indicated that 60-70% of the incorporated $^{63}\text{Ni}^{2+}$ was associated with the nuclear and cell-sap fractions, with 50% of the nucleus-associated radioactivity being bound to the nucleolus. Twenty to 25% of the $^{63}\text{Ni}^{2+}$ was found in the mitochondrial fraction and 10% was associated with the microsomal fraction.

- 3707 CARCINOGENICITY EXAMINATION OF SOME EDIBLE PLANTS. (E.) Hirono, I. (Gifu U. Sch. Med., Japan), C. Shibuya, M. Shimizu, K. Fushimi, H. Mori and T. Miwa. *Gann* 63(3):383-386, 1972.

One hundred and thirty-five ACI rats were fed pellets containing preparations of food plants eaten by the Japanese; feeding periods ranged from 7-337 days. *Artemisia*, horsetail fern, osmund frond and a commercial preparation of osmund frond, and ginkgo nut kernels were among edible plants tested. The only tumors developed by test rats were a pituitary adenoma in an *artemisia*-fed rat, a glioma in an osmund frond-fed rat, and a mammary fibroadenoma in a rat fed a commercial preparation of dried osmund frond.

- 3708 CARCINOGENESIS AND ALKYLATION OF RAT LIVER NUCLEIC ACIDS BY NITROSOMETHYLUREA AND NITROSOETHYLUREA ADMINISTERED BY INTRAPORTAL INJECTION. (E.) Lijinsky, W. (U. Nebraska Med. Ctr., Omaha), H. Garcia, L. Keefer, J. Loo and A. E. Ross. *Cancer Res* 32(5):893-897, 1972.

Groups of 20 male and female 10-to-12-wk-old MRC rats received 5 ml 0.9% NaCl solution containing

either 10 mg nitrosomethylurea (NMU) or 30 mg nitrosoethylurea (NEU) injected into the hepatic portal vein. A control group of 20 rats received intraportal injections of NaCl solution only. The alkylation of nucleic acid guanine was studied in groups of similarly treated rats except that NMU- d_3 and NEU- d_3 were used instead of unlabeled material. The animals were killed five hr after the operation and the livers were removed. The nucleic acids were hydrolyzed and chromatographed on Dowex 50(H^+) columns. Material eluting in the 7-alkylguanine (7-methylguanine, 7-MG and 7-ethylguanine, 7-EG) fraction was further purified by paper chromatography and 7-MG and 7-EG quantities were determined by mass spectrometry. Electron microscopic studies were performed on liver from five hr postoperation rats. Histologic examination of organs from NMU- and NEU-treated and from control rats revealed that almost every animal treated with either NMU (12 rats) or NEU (13 rats), and surviving beyond the 40th week, developed one or more tumors. A variety of tumors was seen in many different organs of treated rats and the incidence was considerably higher than in controls (6 rats). Electron and light microscopic examination of liver sections of NMU- and NEU- treated and control rats revealed only minor alterations related to a minor degree of cellular damage. Mass spectroscopic analysis of DNA from treated rats showed no detectable alkylation of DNA. However, d_3 -labeled 7-MG was present in RNA of NMU-treated rats. No 7-EG was detected in RNA from NEU-treated animals. This difference in ability to alkylate nucleic acids could not be correlated with the similar tumorigenic activity of NMU and NEU. The identification of methyl- d_3 -guanine as the base formed from NMU- d_3 showed that diazomethane was not an intermediate in nucleic acid alkylation by NMU.

- 3709 BINDING OF K-REGION EPOXIDES AND OTHER DERIVATIVES OF BENZ(a)ANTHRACENE AND DIBENZ(a,h)ANTHRACENE TO DNA, RNA, AND PROTEINS OF TRANSFORMABLE CELLS. (E.) Kuroki, T. (McArdle Lab. Cancer Res., U. Wisconsin, Madison), E. Huberman, H. Marquardt, J. K. Selkirk, C. Heidelberger, P. L. Grover and P. Sims. *Chem-Biol Interact* 4(6):389-397, 1971/72.

Hamster embryo cells and C3H mouse prostate cells, both transformable by carcinogenic hydrocarbons and K-region epoxides, mutable hamster cells and C3H mouse prostate tumor cells were treated with benz(a)-anthracene (BA) or dibenz(a,h)anthracene (DBA) or their K-region epoxides, *cis*-dihydrodiols or phenols. Binding of these agents to DNA, RNA and protein of test cells was observed. The K-region epoxide of BA was bound to DNA, RNA and protein of hamster embryo cells to a much greater extent than was BA itself or the corresponding *cis*-dihydrodiol or phenol. At three hr, the epoxide was bound to DNA and RNA 20-25 times more, and to proteins 60 times more, than BA. The BA phenol was bound extensively to RNA and proteins, but not to DNA, with specific activities about one half those seen with the BA epoxide; the *cis*-dihydrodiol was bound less than

BA itself. Maximum binding of the BA epoxide to hamster embryo cell macromolecules was seen at three hr. The K-region epoxide of DBA was bound to RNA and proteins to a greater extent than other derivatives, but was bound to DNA to a slight extent only. The extent of binding of all compounds to macromolecules of transformable mouse prostate cells was less than to hamster embryo cells, and binding to mouse tumor cells was much less than to hamster embryo cells.

3710 RELATIONSHIPS BETWEEN COVALENT BINDING OF 3'-METHYL-4-DIMETHYLAMINOAZOBENZENE TO LIVER PROTEIN AND INCREASES IN THE LEVEL OF HEPATIC AMP DEAMINASE. (E.) Smith, L. D. (Samuel Roberts Noble Fdn., Inc., Ardmore, Okla.), L. Holman and D. E. Kizer. *Chem-Biol Interact* 4(6):311-320, 1971/72.

Female rats were given 3'-methyl-4-dimethylaminoazobenzene (3'-Me-DAB) in diet (0.06%) or as an intra-abdominal injection (250 mg/kg body wt). Five days after injection, or after four wk of carcinogen feeding, rats were killed, livers were removed, and the binding of 3'-Me-DAB to the 105,000 x g liver supernatant proteins was investigated. 3'-Me-DAB metabolites were bound to supernatant proteins. When supernatant proteins were put through a procedure for purifying AMP deaminase, 3'-Me-DAB metabolites continued to bind to purified proteins. Application of the purification procedure, which increased AMP deaminase activity nine-fold, caused a three-fold enrichment of total azo-dye-protein conjugates, but did not cause enrichment of polar azo proteins. Evidently, some azo-proteins were lost during AMP deaminase purification. In a second experiment, mice were injected with 3'-Me-DAB-ring-¹⁴C and killed five days later. An aliquot of the 105,000 x g liver supernatant which contained the radioactive bound azo dye was subjected to sucrose gradient centrifugation. When gradients were fractionated and analyzed for AMP deaminase and radioactive bound azo dye, most radioactivity was associated with proteins of lower molecular wt than AMP deaminase. When aliquots of the 105,000 x g liver supernatant, which had undergone the AMP deaminase purification procedure, were reacted with antisera specific for AMP deaminase, or subjected to polyacrylamide disc gel electrophoresis, ¹⁴C-azo dye-protein conjugates were readily distinguishable from AMP deaminase proteins. Electrophoresis yielded one AMP deaminase fraction which was free of radioactive label from 3'-Me-DAB. AMP deaminase and the main azo proteins were thought to be distinct. It was concluded that interactions between 3'-Me-DAB and AMP deaminase do not occur, and do not explain the increase of this enzyme in precancerous rat liver.

3711 HEMANGIOENDOTHELIAL SARCOMAS OF THE LIVER IN RATS INDUCED BY DIETHYLNITROSAMINE. (E.) Hadjiolov, D. (Oncol. Res. Inst., Sofia, Bulgaria). *Neoplasma* 19(2):111-114, 1972.

Male Wistar rats were given 1 mg/rat/day of diethyl-

nitrosamine in drinking water, for a total dose of 134 mg/rat. After 22 wk of carcinogen feeding, diethylnitrosamine was discontinued and ten wk later rats were killed and liver tumors were examined. Twenty-three of 25 rats had developed liver tumors; there were nine hemangioendothelial sarcomas. These hemangioendothelial sarcomas showed primitive vascular spaces lined by bizarre tumor cells. Of particular interest for elucidation of the histogenesis of angioblastoma were large areas of tumor parenchyma in which the spongiocymal tumor tissue was replaced by solid cellular clusters consisting of a single type of tumor cell. These tumors appeared to originate from undifferentiated mesenchymal elements possessing specific potentialities for differentiation and formation of primitive vascular spaces.

3712 THE CONVERSION OF THE CARCINOGEN N-HYDROXY-2-FLUORENYL-ACETAMIDE TO o-AMIDOPHENOLS BY RAT LIVER *IN VITRO*: SUBSTRATE SPECIFICITY AND MECHANISM OF THE REACTION. (E.) Gutmann, H. R. (VA Hosp., Minneapolis, Minn.) and R. R. Erickson. *J Biol Chem* 247(3):660-666, 1972.

Previous work demonstrated that the carcinogenic arylhydroxamic acid N-hydroxy-2-fluorenylacetamide (N-hydroxy-2-FAA) was metabolized to the o-amidophenols, 1-hydroxy-2-FAA and 3-hydroxy-2-FAA by an inducible enzyme system associated with the microsomes of rat liver. The present experiments were conducted to define the stereochemistry and mechanism of this reaction. A 600xg supernatant fraction from a liver homogenate of male Holtzman albino rats pretreated with 3-methylcholanthrene, which served as the enzyme source, was incubated with ¹⁴C-labeled substrates and the radioactive reaction products were purified and identified by paper or thin-layer chromatography. Examination of the substrate specificity of the enzymatic rearrangement suggested that the reaction was restricted to arylhydroxamic acids in which the nitrogen was linked to an aromatic system capable of extended conjugation. Determinations of the isotope content of 1-hydroxy- and 3-hydroxy-2-FAA isolated after incubation of the induced enzyme with N-hydroxy-2-FAA, labeled with ¹⁸O in the hydroxy group, indicated that the hydroxyl group was transferred *in toto* from the nitrogen to the carbon atoms of the aromatic system located in a position ortho to the nitrogen. The data are compatible with an intramolecular rearrangement rather than with a previously suggested intermolecular mechanism involving addition of hydroxyl groups from the medium to the resonance forms of an amidonium ion.

3713 TYPE C RNA TUMOR VIRUSES AS DETERMINANTS OF CHEMICAL CARCINOGENESIS: EFFECTS OF SEQUENCE OF TREATMENT. (E.) Price, P. J. (Microbiol. Assoc., Bethesda, Md.), W. A. Suk and A. E. Freeman. *Science* 177(4053):1003-1004, 1972.

The relationship between viral infection and

transformation by chemical carcinogenesis was studied. Fischer rat embryo cell cultures were infected with Rauscher murine leukemia virus (RLV) and at timed intervals following infection, were treated with 3-methylcholanthrene (3MC). Treatment of cells with 0.1, 0.5, or 1.0 $\mu\text{g/ml}$ 3MC at two hr, one wk, two wk, or three wk after infection resulted in the appearance of transformed cell foci in the fourth to sixth subcultures. The transformation was dependent on the presence of virus at the time of 3MC treatment. Transformation was not seen in untreated controls, in cultures given RLV or 3MC alone, or in cultures treated first with 3MC and inoculated with RLV following removal of the carcinogen.

- 3714 CHANGE IN ACID PHOSPHATASE DURING AZO-DYE CARCINOGENESIS. (E.) Kaneko, A. (Sapporo Med. Coll., Japan), K. Dempo and T. Onoe. *Gann* 63(1):41-48, 1972.

Changes of acid phosphatase activity in the liver of male Wistar rats during feeding of 0.06% 3'-methyl-4-(dimethylamino)azobenzene (3'-Me-DAB) for 13 wk were determined. Liver tissue and hepatocyte homogenates were chromatographed on DEAE-cellulose, and acid phosphatase activity was measured using β -glycerophosphate (bGP) and phenyl phosphate (PhP) as substrates. Three liver fractions were examined: a soluble fraction, a protein fraction (Fraction I) which was not adsorbed by the DEAE-cellulose column and a second protein fraction (Fraction II). Three types of acid phosphatase, tentatively designated as A, B and C were found; both A and B types existed in the hepatocyte while type C was mainly derived from Fraction II. Type B was found in adult liver and type A in immature liver. In addition, types A and B were detected in Fraction I and type C in Fraction II. Types A and C had higher PhP/bGP activity ratios than type B. Acid phosphatase activity with bGP decreased markedly within four wk after dye feeding but that with PhP showed only a slight decrease. In the 4-8 wk phase, an activity peak at the sixth wk corresponded to the period of increase of small hepatocytes; a rise in the PhP/bGP value was seen at this time. After 9 wk of dye feeding, most of the small regenerated hepatocytes grew to adult size and the PhP/bGP ratio was higher than in previous weeks. Acid phosphatase activity returned to nearly level after 12 wk of dye feeding and then 8 wk of normal diet; however, the PhP/bGP ratio was still slightly higher than normal. The hepatocytes renewed during the dye feeding differed from regenerated hepatocytes after partial hepatectomy; the ratio of acid phosphate activity was elevated in the former and normal in the latter.

3725 CHANGE IN VOLUME OF IRRADIATED HUMAN METASTASES: INVESTIGATION OF REPAIR OF SUBLETHAL DAMAGE AND TUMOUR REPOPULATION. (E.)

Malaise, E. P. (Inst. Gustave Roussy, Villejuif, France), A. Charbit, N. Chavaudra, P. F. Combes, J. Douchez and M. Tubiana. *Brit J Cancer* 26(1): 43-52, 1972.

Twenty-one patients with multiple pulmonary tumor metastases were exposed to Cobalt 60 irradiation, one lung of each patient receiving a single dose of 1000 rad and the other lung two doses of 500 rad separated by a three-hour interval. Tumors usually decreased in size after irradiation. The time taken by a tumor after irradiation to reach a volume equal to half its pre-irradiation volume ("half-regression time") was measured. In metastases exposed to one 1000 rad irradiation, the half-regression time was 14 days; in metastases exposed to two 500 rad irradiations, the half-regression time was 15.5 days. Growth rates of metastases recurring after irradiation were always more rapid than growth rates before irradiation; the regrowth doubling time (i.e., time taken by a tumor to double its size) of metastases averaged five times shorter than the initial, pre-irradiation doubling time. Growth rates of metastases before irradiation correlated significantly with the rate of decrease in tumor volume after irradiation; the rate of decrease was slower when tumor doubling time before irradiation was longer. For seven patients the simultaneous influence of 1000 rad and 500 rad twice was followed through the regrowth of ten metastases. The extrapolation number, n , of the survival curve of metastases cells was calculated for these patients by comparing in each patient the effects of the two types of exposure. The extrapolation number, n , is equal to the value of S_1/S_2 , where S_1 is the proportion of cells surviving an irradiation dose D and S_2 is the proportion of cells surviving an irradiation a dose $2D$. Values for n were not very high; six of seven n values fell between 0.8 and 2.1.

3726 CYTOLOGIC ASPECT OF RF RADIATION IN THE MONKEY. (E.) Prince, J. E. (USAF Sch.

Aerospace Med., Brooks Air Force Base, Texas), L. H. Mori, J. W. Frazer and J. C. Mitchell. *Aerospace Med* 43(7):759-761, 1972.

A circulating lymphocytoid (high nucleus-to-cytoplasm ratio) cell having a high mitotic potential was obtained from the blood of monkeys (Macaca mulatta) 71 hr after whole body exposure to 10.5, 19.7 or 26.6 MHz electromagnetic radiation for 30 min at a power density of 1.32 W/cm². Mitotic potential, estimated by the degree of response to phytohemagglutinin stimulation *in vitro*, was 7 to 11 times greater in lymphocytoid cells from the radiation-exposed animals than in cells from the same animals before exposure. These results indicate that electromagnetic radiation is able to transform certain races of lymphocytoid cells into blood-borne cells of high mitotic potential.

3727 REDUCED INCIDENCE OF X-RAY INDUCED LEUKEMIA AFTER TREATMENT WITH ANTI-LYMPHOCYTE SERUM.

(E.) Balner, H. (Radiobiological Inst. TNO, Rijswijk, Netherlands). *Rev Europe Etudes Clin Biol* 16(10):981-986, 1971.

The influence of antilymphocyte serum (ALS) on the development of X-ray induced leukemia in mice was investigated. Two types of antisera of about equal immunosuppressive potency were used, one raised in rabbits, the other in a horse. Lymphomas were induced with four doses of 150 R total body irradiation, given at weekly intervals; ALS treatment was started the week thereafter and continued for three months (0.5 or 1.0 ml per week, i.p.). Horse ALS did not affect incidence and latency periods of lymphomas but mice treated with rabbit sera failed to develop lymphomas. This unexpected result might be attributed to the presence of antibodies to murine leukemia virus in the rabbit ALS (for which preliminary evidence has been obtained). Alternatively, the rabbit ALS could have had a more pronounced cytotoxic effect than the horse serum on developing lymphoid tumor cells. As in previous experiments, prolonged ALS treatment did not affect incidence and latency periods of malignancies other than lymphomas.

3728 LATE-APPEARING (RADIATION-INDUCED) CARCINOMA: CARCINOMAS OF POSTCRICOID AND HYPOPHARYNGEAL REGIONS FOLLOWING SUCCESSFUL IRRADIATION THERAPY FOR LARYNGEAL CARCINOMA. (E.) Schindel, J. (U. Tel Aviv Med. Sch., Petah Tikva, Israel) and I. M. Castoriano. *Arch Otolaryng* 95(3):205-210, 1972.

Five cases of carcinoma in the postcricoid and hypopharyngeal regions following therapeutic irradiation of the laryngeal region are reported. Patients were all males, and ranged in age from 59-75 yrs. In all cases, carcinoma of one or both vocal cords was treated by irradiation; total radiation doses ranged from 4000 to 6480 rads. Postcricoid or hypopharyngeal carcinomas appeared between 7 and 12 yr after radiation, and were thought to have been caused by radiation.

3729 EFFECTS OF RADIATION ON SPECIFIC CELLULAR IMMUNITIES: BESNOITIOSIS AND A HERPESVIRUS INFECTION OF HAMSTERS. (E.) Frenkel, J. K. (U. Kansas Sch. Med., Kansas City) and H. R. Wilson. *J Infect Dis* 125(3):216-230, 1972.

Hamsters were exposed to gamma irradiation [$LD_{50} = 900-925$ röntgens (r)] before or after s.c. inoculation with *Besnoitia jellisoni*; sulfadiazine in drinking water was given beginning on the day of *Besnoitia* injection to protect against *Besnoitia* infection. Hamsters given 100-300 r survived *Besnoitia* infection, but a third of those given 400 r and all of those giving 500-800 r succumbed to besnoitiosis. The antibody response to *Besnoitia* was delayed or inhibited.

ited in hamsters given 400 or 500 r. Irradiation with 600 r, the maximally immunosuppressive dose, 22 days before to 28 days after infection impaired immunity to *Besnoitia*. However, antibody production was markedly impaired only by 600 r given four or 24 hr after *Besnoitia*. Relapse occurred in 33% of immune hamsters given radiation doses accumulating to 900 r or more. Relapse occurred in all irradiated hamsters treated with cortisone. Adoptive transfer of immunity to *Besnoitia* by means of immune donor cells was studied in normal and irradiated hamsters. Syngeneic immune cells protected most recipients against infection whether or not recipients had been irradiated; allogeneic immune cells protected only irradiated recipients. Allogeneic immune cells protected against infection when recipients were given 0 r but not 800-1000 r; 300-600 r partially facilitated protection. Lymphoid cells of donors given 0 or 100 r showed diminution or abolition of the capacity to transfer adoptive immunity to recipients. either 100 nor 1600 r released demonstrable cell immunity factors into plasma or serum of hamsters given these radiation doses. Irradiation did not effect transfer of immunity to hamsters later challenged with listeriosis or equine rhinopneumonitis.

3730 VITAMIN A AND THE RADIATION RESPONSE OF EXPERIMENTAL TUMORS: AN IMMUNE-MEDIATED EFFECT. (E.) Tannock, I. F. (M. D. Anderson Hosp. Tumor Inst., Houston, Texas), H. D. Suit and N. Marshall. *J Nat Cancer Inst* 48(3):731-741, 1972.

The TCD₅₀ values (i.e., the mean radiation dose yielding local tumor control in 50% of irradiated animals) were established for a transplanted fibrosarcoma in irradiated normal C3H/Bu mice, in irradiated mice actively sensitized to the fibrosarcoma by injections of lethally irradiated fibrosarcoma cells and in irradiated mice immunosuppressed by 0 rads whole-body irradiation. The fibrosarcoma was strongly antigenic in C3H/He mice. The effect of vitamin A injections on TCD₅₀ were observed. Vitamin A had no effect on TCD₅₀ of the fibrosarcoma in immunosuppressed mice, but caused a reduction of 0 rads (15-20% reduction) in the TCD₅₀ of tumors growing in normal mice. The TCD₅₀ for the fibrosarcoma in mice sensitized to their tumor before tumor transplantation was slightly higher than the TCD₅₀ of the tumor in normals. Vitamin A led to a 25% reduction in TCD₅₀ in sensitized mice. Vitamin A had no effect on the TCD₅₀ of a mammary carcinoma which was only weakly antigenic in C3H/He mice. The effect of vitamin A on the radiation response of two normal tissues was observed. Vitamin A did not affect the epilation response to radiation in skin cells or the regeneration response of irradiated intestinal crypt cells. Further, vitamin A did not affect the TD₅₀ (i.e., mean number of tumor cells required to generate tumors in 50% of mice) in a suspension of viable fibrosarcoma cells was injected into neonatal mice. However, injection of vitamin A into mice which had received an inoculum of mixed viable and lethally irradiated tumor cells led to a significantly higher TD₅₀ value than was seen in mice not given vitamin A.

3731 RADIATION-INDUCED DNA SYNTHESIS IN NUCLEI OF HEN ERYTHROCYTES REACTIVATED IN HETEROKARYONS. (E.) Darzynkiewicz, Z. (Boston Biomed. Res. Inst., Mass.). *Expt Cell Res* 69:477-481, 1972.

A study to determine if avian erythrocytes are able to effect DNA repair and whether this ability is altered during nuclear reactivation in heterokaryons is reported. Chicken embryo erythrocytes, whether non-irradiated or UV light-irradiated, incorporated negligible amounts of ³H-TdR into the nuclei. The presence of tritium in the cells - revealed by "dry" autoradiography - indicated that the precursor can penetrate the cells but is not incorporated into macromolecules. Erythrocyte nuclei reactivated in HeLa cells incorporated less ³H-TdR after UV light irradiation than nuclei reactivated in fibroblasts. Assuming that UV light-induced ³H-TdR incorporation reflects DNA repair replication, chicken embryo erythrocytes could not repair DNA. However, the ability to repair DNA was rapidly restored following reactivation of erythrocyte nuclei in the cytoplasm of rat or HeLa cells. The results indicate that cytoplasmic factors are significant in reactivation of dormant nuclei in heterokaryons, i.e., the enzymes that repair DNA may migrate from the active to the reactivated nuclei via the cytoplasm of the heterokaryon.

3732 THE ROLE OF MUTATIONS IN LIVER TUMOR INDUCTION IN MICE. (E.) Curtis, H. J. (Brookhaven Natl. Lab., Upton, N.Y.) and J. Tilley. *Radiat Res* 50(3):539-542, 1972.

Female LAF₁ mice were given whole-body neutron irradiation at ten wk of age; at 12 and 14 wk of age, mice were given 0.005 ml/g body wt CCl₄. In groups of mice given 0, 27.1, 64.0, 81.5 and 128 rads neutron radiation, resp., liver tumors developed in 10.0, 19.4, 33.3, 58.8 and 60.5% of cases, resp. It had been thought that the tumor induction process in this system proceeds in at least two steps, a mutation followed by a stimulus for cell division. The linear relation between tumor induction and neutron dose suggests that only one mutation is involved in the first step.

3733 TUMOR GROWTH IN ALLOGENEIC MICE BEARING A LUCITE CYLINDER. (E.) Saal, F. (Inst. Hematology Res., Buenos Aires, Argentina), M. E. M. Colmerauer, R. C. Braylan and C. D. Pasqualini. *J Nat Cancer Inst* 49(2):451-458, 1972.

3736 OSTEOGENIC SARCOMA OF HEAD AND NECK INDUCED BY RADIATION THERAPY. (E.) Arlen, M. (Mem. Hosp.-Sloan-Kettering Cancer Ctr., New York, N.Y.), I. C. Shah, N. Higinbotham and A. J. Huvos. *New York J Med* 72:929-934, 1972.

VIRAL CARCINOGENESIS

3737 ISOLATION OF A HERPES-LIKE VIRUS FROM LYMPHOSARCOMATOUS CATTLE. (E.)

Van Der Maaten, M. J. (Nat'l. Animal Dis. Lab., U.S. Dept. Agriculture, Ames, Iowa) and A. D. Boothe. *Arch Gesamte Virusforsch* 37:85-96, 1972.

Apparently identical herpes-like viruses were isolated from two lymphosarcomatous cows in a "multiple-incidence-lymphosarcoma" herd. The isolates induced syncytium formation in bovine embryonic spleen cultures, but electron microscopic studies and indirect immunofluorescence tests indicated that they were structurally and antigenically unrelated to a bovine syncytial virus previously isolated and described by others. The isolates also showed no antigenic relation to infectious bovine rhinotracheitis virus and pseudorabies virus. Inoculation of the isolates into guinea pigs, mice, hamsters, rabbits and calves failed to induce any pathogenicity; however, the herpes-like virus was reisolated from three inoculated calves. The herpes-like virus may be related to the bovine herpes mamillitis and Allerton viruses. There was no evidence directly associating the virus with the lymphoid neoplasms found in the cattle from which it was isolated.

3738 FACTOR-DEPENDENT BINDING OF RAUSCHER LEUKEMIA VIRUS RNA TO RIBOSOMES. (E.)

Lang, C. S. (Dept. Biol., U. Texas, Houston), R. Naso and R. B. Arlinghaus. *Biochem Biophys Res Commun* 47(6):1290-1298, 1972.

³H-labeled Rauscher leukemia virus (RLV) RNA was able to bind to structures which sedimented in sucrose gradients as dimeric through pentameric polyribosomes when incubated in a cell-free amino acid incorporation system derived from RLV-infected JLS-9 cells. The binding of RLV-RNA to ribosomes required the presence of a high-salt wash fraction obtained from JLS-V5 polyribosomes. A decrease in ³H-labeled RLV RNA in the polysome fractions beginning after an incubation period of 30 min paralleled a decrease in incorporation of ¹⁴C-amino acids into polyribosome-associated protein. Addition of aurintricarboxylic acid (ATA, 10⁻⁴ M) caused dissociation of ³H-labeled RLV RNA from the reformed polyribosome complex. The RLV RNA-polyribosome structures were also sensitive to EDTA and RNase treatment.

3739 CAMPTOTHECIN: MECHANISM OF INHIBITION OF ADENOVIRUS FORMATION. (E.) Horwitz, M.

(Albert Einstein Coll. Med., New York, N.Y.) and C. Brayton. *Virology* 48(3):690-698, 1972.

The mechanism of inhibition of adenovirus type 2 formation by the antineoplastic agent camptothecin was studied in infected HeLa cells. Virus formation was measured by the extent of ¹⁴C-thymidine incorporation into mature virions purified on CsCl gradients. Addition of camptothecin, at concentrations greater than 3.3x10⁻⁸ M, immediately following

virus adsorption completely inhibited the formation of adenovirus 12. The inhibition of morphogenesis was paralleled by an inhibition of ¹⁴C-thymidine incorporation into viral DNA purified on alkaline sucrose gradients. Pulse label experiments with ¹⁴C-valine and ¹⁴C-threonine showed that under conditions in which viral DNA synthesis was inhibited by camptothecin, protein synthesis was unaffected. Polyacrylamide gel electrophoresis indicated that all proteins made in the control culture were synthesized in the presence of the drug. These findings suggest that camptothecin acted directly upon DNA and did not inhibit its synthesis as a result of an inhibition of protein synthesis. Alkaline sucrose gradient centrifugation demonstrated that camptothecin could degrade prelabeled viral DNA from infected cells. No detectable degradation of DNA to acid soluble nucleotides was noted, and removal of the drug resulted in repair of intracellular DNA within 10-15 min. *De novo* synthesis of viral DNA also resumed at a reduced rate after removal of camptothecin from the incubation medium.

3740 YELLOW FEVER VACCINATION, AVIAN LEUKOSIS VIRUS, AND CANCER RISK IN MAN. (E.)

Waters, T. D. (U. Oklahoma Med. Ctr., Oklahoma City), P. S. Anderson, Jr., G. W. Beebe and R. W. Miller. *Science* 177(4043):76-77, 1972.

Veterans Administration death certificates of 2659 white males who died of cancer during the periods 1950-1954 or 1959-1963 were compared with those of a matched group of controls to determine whether immunization during World War II with vaccine against yellow fever played a role in cancer induction. Such vaccines, which were produced from chick embryos, were almost certainly contaminated with oncogenic avian leukosis-sarcoma viruses. Comparison of cases and controls according to history of vaccination, type of cancer, social history and medical history indicated that there was no association between yellow fever vaccination and cancer. Comparison of the two groups on the basis of date of death suggested that yellow fever vaccination had not influenced the risk of subsequent cancer. These results indicate that the avian leukosis-sarcoma viruses do not induce cancer in man.

3741 STUDIES OF SV40 DNA. III. DIFFERENCES IN DNA FROM VARIOUS STRAINS OF SV40. (E.)

Nathans, D. (Johns Hopkins U. Sch. Med., Baltimore, Md.) and K. J. Danna. *J Molec Biol* 64(2):515-518, 1972.

The DNA of different SV40 strains was analyzed by digestion with restriction endonuclease from *Hemophilus influenzae* followed by separation of the resulting DNA fragments on polyacrylamide gels. As previously reported, DNA from small plaque SV40 yielded 11 fragments (A through K) ranging from a molecular wt of 6.5x10⁵ daltons (A) to 7.4x10⁴ daltons (K). The same pattern was obtained from

digests of DNA from three different small plaque SV40 stocks whether the DNA was prepared from purified complete virions or from infected cells. "Fingerprints" from large plaque SV40 differed from those of small plaque virus in that the former had two well-separated fragments instead of a poorly resolved E + F peak. In the minute plaque DNA digest, fragment C was absent or considerably decreased and a new, smaller fragment migrating between F and G was present. The electrophoretic pattern of DNA fragments from SV68 was identical to that of minute plaque virus even though SV68 has a small-plaque phenotype. These specific differences may be due simply to the presence of small deletions in the DNA of some strains and their absence in others.

- 3742 REVERSE TRANSCRIPTASE, RNA TUMOUR VIRUS TRANSFORMATION AND DERIVATIVES OF RIFAMYCIN SV. (E.) Ting, R. C. (Bionetics Res. Labs., Bethesda, Md.), S. S. Yang and R. C. Gallo. *Nature New Biol* 236(67):163-166, 1972.

The effect of rifamycin derivatives on focus-forming ability and reverse transcriptase activity of murine sarcoma virus (MSV) and Rauscher leukemia virus (RLV) was studied. Normal rat kidney cell cultures were used as indicator cells in focus-forming assays. The rifamycin derivatives were divided into three classes based on their ability to inhibit viral reverse transcriptase. RLV or MSV were preincubated with inhibitors (100 µg/ml, 30 min) and washed virus lysates were assayed for reverse transcriptase activity. The ability of the rifamycin derivatives to inhibit reverse transcriptase correlated well with the degree of prevention of focus formation. No such correlation between loss of infectivity and inhibition of enzyme activity was observed with rifamycin-treated nononcogenic RNA viruses possessing an RNA-dependent RNA polymerase. These results suggest that reverse transcriptase is necessary for transformation by RNA tumor viruses.

- 3743 PROTEINS OF HELPER-DEPENDENT RSV. (E.) Scheele, C. M. (Public Hlth. Res. Inst. City New York, Inc., N.Y.) and H. Hanafusa. *Virology* 45(2):401-410, 1971.

Electrophoretic analysis of purified avian leukosis and sarcoma viruses is described. The viruses were cultured in chick cells containing or lacking a genetic element termed cell-associated helper factor (chf) which complements Bryan strain Rous sarcoma virus (RSV) with envelope structures. Differences in protein components of infectious and noninfectious RSV and avian leukosis virus in the presence and absence of chf were determined on the basis of viral glycoprotein structure. RAV-2, RAV-60 and SR-RSV each contained at least seven proteins, one of which was a major glycoprotein with low electrophoretic mobility. Bryan RSV differed

from SR-RSV and the avian leukosis viruses primarily in possessing multiple glycoproteins of low electrophoretic mobility. The heterogeneity of the carbohydrate-labeled material varied according to the growth of Bryan RSV in chf positive and chf negative cells. In the absence of chf, a major slowly migrating glycoprotein was missing from Bryan RSV. This observation supports the hypothesis that the failure of Bryan RSV to produce infectious progeny is due to its inability to synthesize antigenic component(s) of the viral envelope.

- 3744 EPSTEIN-BARR VIRUS ANTIBODY LEVELS IN CHILDREN FROM THE WEST NILE DISTRICT OF UGANDA. REPORT OF A FIELD STUDY. (E.) Kafuko, G. W. (East African Virus Res. Inst., Entebbe, Uganda), B. G. Kirya, B. E. Henderson, G. M. R. Munube, P. M. Tukey, N. E. Day, G. Henle, W. Henle, R. H. Morrow, M. C. Pike, P. G. Smith and E. H. Williams. *Lancet* (7753):706-709, 1972.

A pilot study to test the feasibility of a long-term cohort investigation into the relationship of Epstein-Barr (EB) virus to Burkitt's lymphoma was undertaken in the West Nile District of Uganda, where Burkitt's lymphoma is endemic. Antibodies to EB virus were assessed by the indirect immunofluorescence method using sera obtained in an initial study (November 1968) from 1122 children aged 15 and under. In both males and females, the proportion of positive titers was highest (90%) in the two to three yr age group and declined gradually for each additional yr of age to 75% at age 15. High titers were more common among young females than young males. The percentage of females with high titers, however, declined rapidly with age, and became comparable to that of males after age eight. In contrast, the proportion of high titers in boys between two and 13 yr was almost constant. Six months after the initial survey, a resurvey was conducted and 97% of the original registrants were still available. Eighteen months after the initial serum collection, a second collection was made from 447 children. Ten of the 378 (2.6%) initially positive children had negative titers at the second survey. Such reversion was most common in those who had had initially low titers. Twenty-two of 69 (32%) who had negative titers in the first survey had become positive. The antibody titers in the 378 initially positive children showed considerable stability with 57% remaining unchanged and 90% changing by not more than one dilution. Children aged three or under tended to have greater lability of titers. Thirty-nine of the 447 (8.7%) children had persistently high titers. Both labile and persistently high titers were independent of sex or age. Although there was geographical variation in the proportion of children with EB virus antibodies consistent with a recent epidemic of EB virus, the pattern of variation bore no apparent relationship to the time-space clustering of Burkitt's lymphoma previously reported in the West Nile.

- 3745 VIRAL RNA SUBUNITS IN CELLS TRANSFORMED BY RNA TUMOR VIRUSES. (E.) Tsuchida, N. (Saint Louis U. Sch. Med., Mo.), M. S. Robin and M. Green. *Science* 176(4042):1418-1420, 1972.

The size of the virus-specific RNA species present in cells transformed by murine sarcoma virus (MSV) was studied to determine the relation between the intracellular viral RNA and the 70S genome of RNA tumor viruses. The amount of virus-specific RNA was measured by the hybridization of 70S viral RNA with a ³H-DNA product prepared with purified MSV reverse transcriptase. Virus-specific RNA was detected in MSV-producing transformed rat and mouse cells and in "cryptic" nonvirus-producing transformed hamster cells and nonvirus-producing leukemic mouse spleen cells. From half-saturation curves it was estimated that the cryptic, nonvirus-producing transformed hamster and mouse cells contained only 1/15 the amount of virus-specific RNA as did the transformed virus-producing rat and mouse cells. Virus-specific RNA from the virus-producing cells sedimented in two distinct peaks (35S and 20S) in sucrose gradients. The cryptic nonvirus-producing hamster cells, however, contained only 35S virus-specific RNA. The 35S and 20S viral RNA species may serve either as precursors to the 70S viral RNA genome or as mRNAs in viral protein synthesis. The absence of 20S RNA in the nonvirus-producing hamster cells indicates that this RNA species may not be necessary for maintenance of transformed state.

- 3746 CHARACTERIZATION OF THE GROWTH OF HERPES SIMPLEX VIRUS IN HUMAN LYMPHOID CELLS. (E.) Mizrahi, A. (Roswell Park Memorial Inst., Buffalo, N.Y.), J. R. Mitchen, H. W. von Heyden, J. Minowada and G. E. Moore. *Appl Microbiol* 23(1):145-154, 1972.

Herpes simplex virus was grown in a six-liter suspended culture of an atypical permanent human lymphoid cell line, Roswell Park Memorial Institute no. 8226. The kinetics of virus replication virus replication were established by counting viruses by electron microscopy, plaque formation, and tissue culture infectivity. Levels of DNA polymerase activity were followed during the course of infection. The highest virus yields (10-15 PFU/cell) resulted when the RPMI 1701 medium supplemented with 1-2% fetal bovine serum, when pH was 6.7-7.0, and multiplicity of inoculum was 0.1. The total cells in the culture decreased slightly and an initial viability of 90% was reduced to 20% by 48 hr after the virus infection. DNA-dependent polymerase activity in cultures with high viability remained almost constant for 48 hr, but the enzyme activity decreased as the percentage of dead cells in the culture increased. After 24 and 48 hr crystalline virus patterns were observed in the nuclei of some cells. Most of the virus particles were hexagonal and none had an external envelope. In most mature particles a core of nucleic acid was present. Apparently the virus particles were enveloped as they passed

through the outer membrane of the nucleus since all virus-like particles in the cytoplasm and attached to the cell membrane had envelopes. The results indicate that HSV can replicate in human lymphoid cell lines without stimulation and that HSV infection is progressive although it is not synchronous.

- 3747 INCIDENCE OF HERPESVIRUS ANTIBODY AMONG LEUKEMIC AND NASOPHARYNGEAL CARCINOMA PATIENTS. (E.) Feorino, P. (U.S. Dept. Hlth., Education, Welfare, Atlanta, Ga.), E. L. Palmer and M. L. Martin. *Proc Soc Exp Biol Med* 139(3):913-915, 1972.

Sixty sera from patients with leukemia, 22 sera from patients with nasopharyngeal carcinoma (NPC), and 82 sera from controls were screened for antibodies to type 1 and 2 Herpes Simplex virus (HSV), varicella virus, cytomegalovirus and Epstein Barr virus (EBV). Complement fixation and fluorescent antibody titers to the herpes virus group in sera from leukemic patients were similar to those in their controls. However, patients with NPC had higher titers against HSV type 1, EBV, and varicella virus than their controls. These findings indicate that NPC patients are more susceptible to HSV infections. It is also possible that a latent HSV infection reactivated during NPC illness produces an antibody response to HSV and, in some cases, a concomitant response to varicella virus.

- 3748 SURFACE CHANGES OF HUMAN CELLS PRODUCTIVELY INFECTED WITH HUMAN ADENOVIRUSES. (E.) Salzberg, S. (Saint Louis U. Sch. Med., Mo.) and H. J. Raskas. *Virology* 48(3):631-637, 1972.

Surface membrane changes were detected in human embryonic kidney (HEK) cells productively infected with various human adenoviruses as an increased agglutination in the presence of concanavalin A (Con A). A significant increase in the agglutination of HEK cells by Con A was seen following infection with a group C adenovirus (type 2). The increase was detected as early as five hr after infection and reached a maximum after 40 hr. Viral DNA synthesis, or events dependent upon viral DNA synthesis, was necessary for this effect as treatment of cells with cytosine arabinoside from 8 to 18 hr post-infection (time of maximum viral DNA replication) considerably reduced the extent of agglutination. Infection of HEK cells with a group A adenovirus (type 12), an oncogenic strain, failed to increase agglutinability. However, two adenovirus 12 cytotidal mutants, which have lost the ability to transform permissive cells, did increase the agglutination of infected HEK cells. This result indicated that the ability to produce surface change during productive infection was not necessarily related to the oncogenicity of the virus.

- 3749 CUTANEOUS PAPILLOMAS ON AN OPOSSUM. (E.) Koller, L. D. (Natl. Inst. Environment Hlth. Sci., Research Triangle Park, N.C.). *J Nat Cancer Inst* 49(1):309-313, 1972.

Cutaneous papillomas developed on the left front leg and leg of a one-year-old opossum born and raised in captivity. A small papillomatous cluster was also found on the left ear. The papillomas began to regress six months after their initial appearance and had almost disappeared by one yr. The papillomatous projections had a hyperplastic stratified squamous epithelium and a connective tissue base and core composed primarily of collagen. Virus particles similar to those of the papova group and approximately 50 mμ in diameter were observed in electron micrographs of negatively stained suspensions of disrupted papilloma tissues. Virus-containing suspensions from the opossum wart and from human papillomas failed to produce papillomas in other opossums when inoculated intradermally or rubbed into scarified skin. Precipitation lines did not form in agar gel when the virus-containing suspension was diffused against serum from the tumor-bearing opossum. The possibility that the opossum papillomas originated from exposure to papillomas on the hand of an animal caretaker could not be excluded.

- 3750 SPONTANEOUS TRANSFORMATION OF HUMAN BRAIN CELLS GROWN *IN VITRO* AND DESCRIPTION OF ASSOCIATED VIRUS PARTICLES. (E.) Hooks, J. (Natl. Inst. Neurological Dis. Stroke, Bethesda, Md.), C. J. Gibbs, Jr., H. Choppra, M. Lewis and D. C. Gajdusek. *Science* 176(4042):1420-1422, 1972.

Brain cell cultures originating from a biopsy specimen from a patient with Creutzfeldt-Jakob disease underwent spontaneous transformation. After 60 days, foci of morphologically altered cells began to appear in primary cultures. These cells were epithelial in appearance; they grew rapidly and displayed loss of contact inhibition. Chromosome studies on two subcultures established that the cells were of human origin with a modal chromosome number of 75. One large acrocentric and one or two minute marker chromosomes were observed. Virus particles morphologically similar to known oncogenic RNA virus were observed in various stages of development in the cytoplasm, budding from the plasma membrane and in the extracellular spaces. The viruses closely resembled the Mason-Pfizer monkey virus and visna and foamy viruses. Attempts to infect various cultures of human, monkey and chimpanzee origin were unsuccessful. Radioimmune precipitation assays indicated that transformed cells did not contain group-specific antigen characteristic of the RNA tumor viruses. Transformed cells showed no fluorescence with conjugated antisera prepared against SV40 and polyoma T antigens.

- 3751 MORPHOLOGY OF THYMIC GRAFTS EXPOSED TO LYMPHOMAGENIC VIRUS. (E.) Hays, E. F.

(U. California Sch. Med., Los Angeles). *J Surg Oncol* 3(5):517-523, 1971.

Syngeneic thymic grafts in 48 AKR mice were exposed *in vitro* to lymphomagenic virus, grafted subcutaneously or under the kidney capsule and biopsied at intervals. At biopsy all but three grafts had the microscopic appearance of a normal thymus, yet 47 underwent subsequent transformation to lymphoma. Eight of nine remnant grafts developed lymphoma 71-81 days after grafting, while all 39 intact grafts were transformed after 52-180 days. In two of three intact grafts with lymphoma at biopsy, the lymphoma cells were localized in the cortex. Five lymphomas developed in 21 nonvirus-exposed grafts after a prolonged latent period. Neonatal thymic remnants exposed *in vitro* to virus also had a high incidence of lymphoma compared to nonvirus-exposed remnants. Again no specific prelymphomatous changes preceded initial lymphoma development in the thymic cortex. The effect of exposure to lymphomagenic virus on regeneration of syngeneic thymic epithelial reticular cell grafts was also studied. All grafts regenerated to normal thymus morphology with a characteristic sequence of cellular events. These results imply a direct transformation of cells in the thymic cortex by lymphomagenic virus independent of preceding structural organization. The presence of the virus in epithelial reticular cell grafts does not impair the ability of the cell to recruit precursors of thymic cortical lymphocytes from the host and direct their maturation.

- 3752 THE DEVELOPMENT OF CV-1 CELLS RESISTANT TO SV 40. (E.) Hahn, E. C. (German Cancer Res. Ctr., Heidelberg). *Arch Gesamte Virusforsch* 37:34-44, 1972.

Growing and stationary CV-1 cultures were infected with SV40. The infected, stationary cells were released from growth inhibition two hr after infection by trypsinization. During the first eight days after infection, most cells were destroyed and only small isolated colonies containing two to four cells remained. As the colonies grew, both the fraction of cells capable of producing infective centers and the amount of virus produced per cell decreased. Although less than half of the cells produced infective centers 26 days after infection, all surviving cells contained T antigen. The percentage of cells with V antigen was similar to the fraction of cells which registered as infective centers. By six wk after infection, the SV40-resistant CV-1 (SCV) strains showed altered morphology, a higher rate of proliferation and the ability to grow at low cell densities when compared with normal CV-1 cells. All six established SCV strains continued to produce small quantities of virus; however, the number of infected cells (i.e., those with V antigen) could not be increased by superinfection. The percentage of cells positive for T antigen varied between 10 and 50%. An isolated clone of SCV cells remained free of detectable virus for two months and then spontaneously

began to release SV40. Treatment with anti-SV40 serum decreased the concentration of extracellular virus but had no effect on the intracellular virus concentration. These results are consistent with the hypothesis that both T antigen-positive cells and cells which continued to release SV40 arose from T antigen-negative, abortively transformed cells in which the viral genome was unstably suppressed.

- 3753 STUDY OF INTERFERONOGENIC ACTIVITY OF HERPES SIMPLEX VIRUS. (E.) Rudneva, I. A. (Inst. Virology, USSR Acad. Med. Sci., Moscow), N. I. Korabelnikova, A. B. Germanov, M. I. Sokolov and L. L. Fadeeva. *Arch Ges Virusforsch* 37(1):1-5, 1972.

The interferon-inducing capacity of herpes simplex virus strains belonging to different antigenic groups was studied in chick fibroblast cultures. Interferon was assayed by the plaque-reduction technique using VSV as challenge virus. Only the initial variant of strain K and its plaque-forming clones (serotype 2) proved capable of inducing interferon. Strains ELA (serotype 1) and US (serotype 3) were inactive in this respect. The culture fluid showed the largest amount of interferon at 48 hr after infection with an input multiplicity of 1 PFU/cell. A reduction in multiplicity of infection resulted in a considerable decrease in interferon yield. Strain K clones, which normally form "opaque" plaques in chick fibroblast cultures at 37 C, produced "clear" plaques at 28 C and at 36 C (in the presence of BUDR). In both cases, the formation of clear plaques appeared to be associated with a reduction in interferonogenic activity.

- 3754 SELECTIVE INHIBITION OF NUCLEAR DNA SYNTHESIS BY 9- β -D-ARABINOFURANOSYL ADENINE IN RAT CELLS TRANSFORMED BY ROUS SARCOMA VIRUS. (E.) Shipman, C., Jr. (Dept. Oral Biol., U. Michigan, Ann Arbor), S. H. Smith and J. C. Drach. *Proc Nat Acad Sci USA* 69(7):1753-1757, 1972.

The effect of 9- β -D-Arabinofuranosyl adenine (ara-A) on the synthesis of covalently closed circular (extrachromosomal) DNA in Rous sarcoma virus-transformed B-mix K-44/6 rat cells was studied by addition of various concentrations of the drug to cells in medium containing ^3H -thymidine. After nearly all the nuclear DNA was pelleted by the Hirt procedure, the supernatant fractions were centrifuged to equilibrium in a CsCl-propidium diiodide gradient to isolate the covalent closed DNA. Ara-A significantly decreased incorporation of ^3H -thymidine into nuclear DNA (residual DNA in the Hirt supernatant fraction), while incorporation into extrachromosomal DNA was unaffected. The inhibition was linear with respect to ara-A concentration over the range of 37-600 μM . Total DNA synthesis per cell and mitosis were also depressed. On the basis of buoyant density and sedimentation velocity

centrifugation, the covalently closed circular DNA formed in the presence of the drug was indistinguishable from that formed in its absence. Treatment of B-mix K-44/6 cells with 600 μM hydroxyurea did not produce selective inhibition of linear DNA.

- 3755 VARIATION IN PROPERTIES OF SV40-TRANSFORMED SIMIAN CELL LINES DETECTED BY SUPERINFECTION WITH SV40 AND HUMAN ADENOVIRUSES. (E.) Butel, J. S. (Baylor Coll. Med., Houston, Texas), L. S. Richardson and J. L. Melnick. *Virology* 46(3):844-855, 1971.

The susceptibility to superinfection with SV40 of four cell lines already transformed by complete or defective SV40 was observed. The lines were: BSC-1-S monkey cells transformed *in vitro* by complete SV40; BGL-1-S baby green monkey lung cells transformed *in vitro* by complete SV40; T-22 green monkey kidney cells transformed *in vitro* by irradiated T antigen-forming particles of SV40; and H-5 green monkey kidney cells transformed *in vitro* by irradiated parental PARA adenovirus 7. When cells were superinfected with whole SV40, H-5 cells were susceptible to superinfection; infecting SV40 replicated well in H-5 cells. T-22 cells supported replication of SV40, but less effectively than H-5. BSC-1-S and BGL-1-S cells were refractory to SV40 superinfection. Cells of the four lines were superinfected with infectious SV40 DNA. BSC-1-S cells were not wholly resistant to infection with SV40 DNA, but BGL-1-S cells were. Cells of the four lines were superinfected with defective SV40 (PARA) and with a cytoplasmic mutant of PARA. Both parental and mutant PARA replicated in all four transformed cell lines. After infection with mutant PARA, more than 99% of cells in each line showed SV40 T antigen in an intranuclear location. The BGL-1-S line failed to support superinfection with human adenoviruses, but the other three SV40-transformed lines were susceptible to human adenoviruses.

- 3756 TRANSFORMATION OF GUINEA PIG EMBRYO CELLS BY A MURINE SARCOMA VIRUS. (E.) Rhim, J. S. (Microbiological Associates, Inc., Bethesda, Md.), C. F. Demoise, F. G. Duh and H. Y. Cho. *Virology* 48(3):841-843, 1972.

Experiments are reported which show that guinea pig embryo (GPE) cells can be transformed morphologically *in vitro* by the Kirsten mouse sarcoma virus (Ki-MSV). Approximately 15-20 days after infection of GPE cultures, foci of fusiform and rounded cells appeared which increased in size. The foci became quite distinct after one passage of the GPE culture. The foci were similar to those seen in Ki-MSV-transformed mouse and rat embryo cells and showed a multilayered pattern of growth. Transformed cells continuously released virus, and cell-free preparations of supernatant fluid from such cultures produced similar foci in cultured NIH Swiss mouse embryo, rat and GPE cells. The transformed cell contained high titers of the group-specific (gs) complement-

fixing antigen characteristic of the murine sarcoma-leukemia virus complex. Radiolabeled virus from supernatant fluids banded at a density of 1.15 g/cc in sucrose gradients. The ability of guinea pig cell-grown virus to transform GPE cells faster than the original virus indicates that the GPE cell grown virus may have acquired new properties. Other C type viruses, including the Moloney and Harvey isolates of MAV and the Theilen strain of feline sarcoma virus, were unable to transform GPE cells.

- 3757 FLUORESCENT ANTIBODY STUDIES ON HERPESVIRUSES FROM NEW-WORLD PRIMATES. (E.) Fraser, C. E. O. (Harvard Med. Sch., Southborough, Mass.), L. V. Melendez, M. D. Daniel and H. H. Barahona. *J Nat Cancer Inst* 49(1):291-294, 1972.

A study was undertaken to explore the extent to which fluorescent antibodies (FA) would be useful in identifying and differentiating several herpesviruses isolated from new-world primates. Virus from infected primates was used to infect owl monkey kidney, rabbit kidney or goat synovial bursa cell lines, which were then assayed by the indirect FA staining technique using virus-specific antisera. The results were compared with results from serum neutralization tests. The FA technique was as highly specific as the accepted neutralization antibody (NA) test in identifying the different herpesviruses. Poly I:C treatment of goats used to prepare the antisera had the effect of suppressing FA titers, but seemed not to suppress NA titers to any great extent. This result supports previously published data suggesting that FA are different from NA. It is concluded that FA techniques may be of value in supplementing NA tests for the identification and differentiation of herpesviruses.

- 3758 USE OF AN ESTABLISHED CAT CELL LINE FOR INVESTIGATION AND QUANTITATION OF FELINE ONCORNAVIRUSES. (E.) Lee, K. M. (New York State Vet. Coll., Cornell U., Ithaca), S. Nomura, R. H. Bassin and P. J. Fischinger. *J Nat Cancer Inst* 49(1):55-60, 1972.

Susceptibility of a continuous cat kidney cell line established by Crandell (CCC) to focus formation by a feline leukemia pseudotype of murine sarcoma virus [MSV(FeLV)] was compared to that of feline embryonic fibroblast (FEF) cultures. CCC was almost as susceptible to infection with MSV(FeLV) as FEF, the usual cell of choice in studies with feline oncornaviruses; virus titers on CCC were only three-fold lower than those of FEF. The MSV(FeLV) stock showed a characteristic "two-hit" titration pattern when assayed on both CCC and FEF or without addition of DEAE-dextran to the assay plates. In the presence of added FeLV, the number of foci formed by MSV(FeLV) was increased and the titration pattern became essentially "one-hit". Pretreatment of both CCC and

FEF cultures with DEAE-dextran enhanced by three-to four-fold the focus formation by MSV(FeLV) either alone or with exogenous FeLV. Preinfection of CCC cultures with FeLV or the Gardner-Arnstein strain of feline sarcoma virus induced resistance to challenge with MSV(FeLV). In addition, colonies of transformed cells were produced in semisolid agar suspension cultures after infection of CCC with MSV(FeLV).

- 3759 VIRUSES AND RENAL CARCINOMA OF *RANA PIPIENS*. XIII. TRANSMISSION OF THE LUCKE TUMOR BY HERPESVIRUS-CONTAINING ASCITIC FLUID FROM A TUMOR-BEARING FROG. (E.) Naegelé, R. F. (St. Jude Children's Res. Hosp., Memphis, Tenn.) and A. Granoff. *J Nat Cancer Inst* 49(1):299-303, 1972.

Undiluted herpesvirus-positive (by electron microscopy) ascitic fluid obtained from a Lucké tumor-bearing male *R. pipiens* was injected into the nephrogenic ridge of tailbud embryos. Cystic-papillary renal adenocarcinomas were detected in 7 of 87 animals examined between 72 and 99 days after inoculation. All lacked intranuclear inclusions. These results demonstrate that the etiologic agent of the Lucké adenocarcinoma was present in the ascitic fluid and support the hypothesis of vertical transmission of the tumor.

- 3760 SYNTHESIS OF VIRAL RNA BY HUMAN DIPLOID CELLS TRANSFORMED BY BLOOD FROM A PATIENT WITH HEMOCYTOBLASTOSIS. (Rus.) Andzhaparidze, O. G. (Moscow Res. Inst. Virus Prep., USSR), G. Ya. Solov'ev and L. G. Stepanova. *Vop Virusol* 16(4):460-462, 1971.

A culture of human diploid cells was inoculated with fluid from a T-9 cell line, transformed by blood from a patient with hemocytoblastosis. Portions of the inoculated cells were incubated with ³H-uridine and ¹⁴C-thymidine in a mixture of 68% Eagle's medium, 30% lactalbumin hydrolysate, and 2% calf serum for 0-24 or 48-72 hr and centrifuged in a sucrose density gradient. The sucrose density, and radioactivity distribution were measured after centrifugation. Particles having a flotation density of 1.17 g/ml in the sucrose gradient were separated on the 1st day of inoculation. Thymidine incorporation and detection of the tracer on the 1st day after inoculation are explained by the fact that there are two classes of particles: one class containing RNA (viruses) and the other containing DNA (mycoplasma). It is concluded that hemocytoblastosis is caused by the leukemia-like virus.

- 3761 SEROLOGICAL RELATIONSHIPS AMONG HERPESVIRUSES: CROSS-REACTION BETWEEN MAREK'S DISEASE VIRUS AND PSEUDORABIES VIRUS AS DETECTED BY IMMUNOFLOUORESCENCE. (E.) Sharma, J. M. (Coll. Vet. Med., Washington State

U., Pullman), D. Burger and S. G. Kenzy. *Infect Immunology* 5(3):406-411, 1972.

Sera from chickens with Marek's disease virus (MDV) cross-reacted with several pseudorabies virus (PRV)-infected cell systems by the fluorescent antibody test but not by gel diffusion, virus neutralization, or cross-protection tests. Herpesvirus of turkeys cross-reacted with MDV but not with PRV. Infectious laryngotracheitis virus, equine herpesvirus, and rabbit herpesvirus did not have cross-reactions. The observed cross-reaction of MDV and PRV is of interest because MDV is a cell-associated virus with restricted host range and has a DNA with a guanine-plus-cytosine content of 56 moles per hundred. In contrast, PRV has a wide host range, is readily released from infected cells into culture fluid, and has a DNA with a guanine-plus-cytosine content of 74 moles per hundred.

3762 INTERACTIONS BETWEEN MAREK'S DISEASE HERPESVIRUS AND AVIAN LEUCOSIS VIRUS IN TISSUE CULTURE. (E.) Frankel, J. W. (Life Sci., Inc., St. Petersburg, Florida) and V. Groupe. *Nature New Biol* 234(47):125-126, 1971.

Experimental data are presented showing that Marek's disease herpesvirus (MDHV) infection of chicken embryo fibroblast cell cultures, previously infected with an avian leucosis virus (RAV-2), reduces the number of MDHV foci and increases the complement fixing avian leucosis antigen (COFAL) titer. MDHV superinfection of primary specific pathogen-free cell cultures, infected with 10^2 - 10^4 50% median tissue culture infective dose/ml of RAV-2, produced an 87-94% reduction in MDHV foci compared with cultures receiving only MDHV. No inhibition of plaque formation by herpes simplex and vesicular stomatitis viruses resulted from MDHV superinfection of primary and secondary RAV-2-infected cultures. COFAL titers were significantly higher in cultures infected with both RAV-2 and MDHV than in cultures infected only with RAV-2.

763 HERPES ZOSTER IN HODGKIN'S DISEASE: CLINICAL, HISTOLOGIC, AND IMMUNOLOGIC CORRELATIONS. (E.) Wilson, J. F. (Nat'l. Cancer Inst., Bethesda, Md.), G. W. Marsa and R. E. Johnson. *Cancer* 29(2):461-465, 1972.

The hundred and sixty-three patients with Stages I-III Hodgkin's disease received radiation therapy. Eighty-three percent (136 patients) had localized disease (Stages I-II) when treatment was initiated. Herpes zoster was observed in 31 patients (19%). One patient gave a history of prior shingles; most had histories of childhood varicella. The incidence of zoster was increased in patients with mixed cellularity Stage III disease, and in those patients with early stages treated with extensive irradiation. Shingles occurred within six months of primary

treatment with nearly equal frequency in both sexes, but the mean age of zoster patients was significantly higher than those not developing the infection. Post-treatment lymphocyte counts at the first three month follow-up visit were evaluated in all 163 patients to compare the degree of immunosuppression resulting from the three radiation regimens; progressive lymphopenia was noted with increasing amounts of irradiation. In the 31 patients developing herpes zoster, recurrent Hodgkin's disease was detected in 16 and multiple myeloma in another. The interval between the completion of radiation therapy and the onset of herpes zoster is significant. If this interval exceeded six months, recurrent Hodgkin's disease followed shortly in ten of 13 patients. When the interval was less than six months, the patients exhibited no unusual morbidity. When zoster is activated after six months, it is reasonable to expect that active lymphoma is then directly involving neural tissue or has renewed the immunosuppression. However, those patients developing herpes zoster closer to the time of treatment reflect the cumulative immunosuppression of active disease and radical irradiation. In this situation, the herpes zoster fails as an ominous prognosticator when definite therapy eradicates Hodgkin's disease.

3764 ENHANCEMENT AND SUPPRESSION OF MURINE SARCOMA VIRUS INDUCED TUMORS BY POLYRIBOINOSINIC-POLYRIBOCYTIDYLIC ACID. (E.) Gazdar, A. F. (Nat'l. Cancer Inst., Bethesda, Md.), A. J. Weinstein, H. L. Sims and A. D. Steinberg. *Proc Soc Exp Biol Med* 139(1):279-285, 1972.

The effects of polyribonoinosinic-polyribocytidylic acid (rI·rC) on the Moloney strain of murine sarcoma virus (MSV) in male and female weanling BALB/c and AL/N mice are reported. Complete suppression of tumor induction was produced in BALB/c mice by i.v. injection of toxic levels (200 µg) of rI·rC starting two hr prior to virus inoculation and continuing every second day. Similar results were obtained with multiple injections of rI·rC at the virus inoculation site. Tumor occurrence was suppressed in BALB/c mice by continuous treatment with rI·rC for 30 days; however, tumors developed shortly after cessation of the regimen. These findings suggest that the tumor suppressive action of rI·rC was more likely mediated by its toxic or chemotherapeutic effects than by direct antiviral action. Pretreatment with a single subtoxic dose of rI·rC and MSV resulted in enhancement of tumor induction in AL/N mice at all virus dilutions tested. The enhancement was a specific action of rI·rC as it could be prevented by prior immunization with double-stranded viral RNA. It is concluded that the relationship between rI·rC and MSV tumor induction is highly complex, depending on multiple factors including the strain of mouse, dose and time of administration of rI·rC, number of injections of rI·rC, site of injection of rI·rC, and dose of MSV.

3765 INDUCTION OF OSTEOSARCOMAS AND OTHER MESENCHYMAL TUMORS BY CELL-FREE EXTRACTS

FROM MICE WITH RADIATION-INDUCED LEUKEMIA. (Fr.) Chamorro, A. (Pasteur Inst., Radium Inst., Paris, France). *C R Acad Sci [D] Paris* 274(7):1121-1124, 1972.

Of 123 Swiss/L mice, aged 35 and 75 days, which were subjected to whole-body irradiation (4 doses of 150 r x-rays each at 8-day intervals), 79 survived and 29 of these developed leukemia (21 had lymphomas and eight had leukemias). The percentage of thymomas (40%) in 75-day-old mice was twice that in 35-day-old mice. Cell-free extracts were prepared from one mouse with a thymoma, one with generalized lymphoma, two with lymphogenous leukemia, and one with myelogenous leukemia. These extracts were then injected i.p. into 97 newborn Swiss mice. Of the 57 mice which survived, five developed lymphogenous leukemia, one developed myelogenous leukemia, while 12 developed mesenchymal tumors (one reticulum-cell sarcoma, seven sarcomas, one osteoma, and three osteogenic sarcomas). In addition, five mice developed leukemic splenomegaly with an elevated WBC; three cases were myeloid in nature. Although the percentage of mice which developed lymphogenous leukemia was not appreciably higher than that which occurs spontaneously, the incidence of leukemic splenomegaly and mesenchymal tumors, particularly osteomas, was significantly higher than would occur spontaneously. These findings suggest that x-rays reactive an oncogenic virus present in the latent state in Swiss/L mice.

3766 DNA POLYMERASES OF TUMOR VIRUS: SPECIFIC EFFECT OF ETHIDIUM BROMIDE ON THE USE OF DIFFERENT SYNTHETIC TEMPLATES. (E.) Fridlender, B. (Roche Inst. Molecular Biol., Nutley, N.J.) and A. Weissbach. *Proc Nat Acad Sci USA* 68(12):3116-3119, 1971.

The RNA-dependent DNA polymerase of avian myeloblastosis virus (AMV), Rauscher mouse leukemia virus (RMLV), Rous avian sarcoma virus (RASV), and feline sarcoma virus (FSV) were distinguished from each other according to degree of inhibition of the enzyme by ethidium bromide (EB) in the presence of specific synthetic primer-templates. With (dT)₉·poly(A) as primer-template, AMV, RMLV, and RASV, but not FSV, polymerases showed high activity. This difference was not apparent when using poly(dA-dT) as a primer-template. When activated salmon-sperm DNA was the primer-template, EB concentrations up to 25 μM inhibited all virus polymerases to the same extent; at 25 μM the inhibition reached 60-80%. With (dT)₉·poly(A) as primer-template, 2.5 μM EB inhibited FSV and RMLV polymerases by 85 and 95%, resp., but AMV and RASV enzymes by only 23 and 29%, resp. Similar though less pronounced differences were observed in enzyme response to EB in the presence of poly(dA-dT) primer-template. Differences in the response of the AMV and RASV enzymes to EB and that of FSV and RMLV polymerases were also noted with (dG)₁₂·poly(dC) and poly(dG·dC) primer-templates. In general, the avian virus enzymes showed up to 30% stimulation of activity and the mammalian viruses up to 50% inhibition.

3767 BINDING OF CONCAVALIN A TO THE ENVELOPE OF TWO MURINE RNA TUMOUR VIRUSES. (E.) Calafat, J. (Netherlands Cancer Inst., Amsterdam) and P. C. Hageman. *J Gen Virol* 14:103-106, 1972.

The binding of concanavalin A (Con A) to the envelope of two RNA tumor viruses that mature at the cell membrane was studied by electron microscopy. B particles of the mouse mammary tumor virus (MTV-s) were purified from mammary tumors of BALB/cDEAFC₃H/HeA or C₃H/HeA mice. C particles of Rauscher murine leukemia virus (RMLV) were purified from the spleens of infected BALB/cDEA mice. Particles were fixed and incubated with 125-5000 μg/ml Con A for 10, 30, or 60 min at room temperature. The particle-Con A complexes were stained with 1% PTA. Both B and C particles were agglutinated in groups by Con A, and there was a thick layer of electron-dense, fairly homogeneous precipitate along the virus membrane. When 0.1 M α-methyl-D-glucoside, a sugar that competes with Con A for binding sites, was added, practically no agglutination or precipitate was seen. Virus treated with peroxidase alone followed by the diaminobenzidine reaction showed no attached precipitate. After negative staining, Con A was seen attached to virus particles. B particles incubated with anti-B particle serum also agglutinated, with antibody covering the virus envelope, indicating that RNA tumor viruses themselves may contribute to the surface changes in tumor cells.

3768 SYNTHESIS AND ASSEMBLY OF SIMIAN VIRUS 40. II. SYNTHESIS OF THE MAJOR CAPSID PROTEIN AND ITS INCORPORATION INTO VIRAL PARTICLES. (E.) Ozer, H. L. (Nat'l. Cancer Inst., Bethesda, Md.) and P. Tegtmeyer. *J Virol* 9(1):52-60, 1972.

African green monkey kidney (Vero) cells infected by SV40 were analyzed for the presence of the major capsid protein (capsid protein I) by immunological and radiolabeling techniques. Antisera with different specificities were prepared by immunization with intact or denatured viral particles. Antisera prepared against intact virus reacted by complement fixation with viral particles and with an 8S subunit containing the capsid protein I. Antisera prepared against denatured viral particles reacted with unassembled capsid proteins as well as with viral particles. Extracts of infected cells were analyzed for viral components using guinea pig antiserum to viral capsid proteins. The soluble antigen pool of the 100,000 x g supernatant was found to be small during infection with wild-type virus or a temperature-sensitive mutant of SV40 deficient in the synthesis of viral particles. SDS polyacrylamide gel electrophoresis of pulse-chase labeled viral capsid proteins purified from the 100,000 x g cell fraction on CsCl cushions was performed. The fact that only a minor increase in the total radioactivity of the capsid protein in viral particles was seen following a two hr pulse after infection at a high multiplicity of infection also indicated a small pool of nonparticle capsid protein I. In the same pulse-chase experiments, capsid protein I

was incorporated preferentially into empty shells during the pulse with a shift in radioactivity to intact virions during the chase period, indicating a possible precursor relationship between the two types of virus particles.

3769 SYNTHESIS OF DNA COMPLEMENTS OF NATURAL RNAs: A GENERAL APPROACH. (E.)

Spiegelman, S. (Coll. Physicians Surg., Columbia U., New York, N.Y.), K. F. Watson and D. L. Kacian. *Proc Nat Acad Sci USA* 68(11):2843-2845, 1971.

The usefulness of purified avian myeloblastosis virus (AMV) RNA-dependent DNA polymerase (reverse transcriptase) as a general tool for synthesizing DNA complements of a wide variety of natural RNAs was investigated. Selective hybridization of product DNA to homologous natural RNA was the criterion for actual synthesis of complementary DNA. AMV reverse transcriptase was able to direct synthesis of DNA complementary to Maloney sarcoma virus and to QB bacteriophage RNAs. In each case the product hybridized to the RNA that was added as template, and not to heterologous RNA. AMV reverse transcriptase is thus able to use various natural RNA templates to synthesize complementary DNA.

3770 EFFECT OF POLYCATIONS ON SENSITIVITY OF BALB/3T3 CELLS TO MURINE LEUKEMIA AND SARCOMA VIRUS INFECTIVITY. (E.) Manning, J. S. (Sch. Public Hlth., U. California, Berkeley), A. J. Lockett and N. B. Darby, Jr. *Appl Microbiol* 22(6):1162-1163, 1971.

The sensitivity of BALB/3T3 cells to infection by murine leukemia virus (MuLV) and murine sarcoma virus (MSV) was markedly increased by the inclusion of 2 µg/ml or more of polybrene in the virus inoculum. Toxic effects were not apparent and the size of plaques or foci was not altered. Inclusion of diethylaminoethyl dextran (DEAE-D) in the virus inoculum significantly enhanced MSV focus formation, but 20 µg/ml was required for the maximum effect. Toxic cellular effects of DEAE-D were eliminated by diluting the reagent-virus inoculum 50-fold immediately after the adsorption period. This procedure, which eliminates the necessity of polycation pretreatment and subsequent extensive washing, may be applicable to *in vitro* viral assay systems other than MuLV and MSV.

3771 DISTINCTIVE EFFECTS OF INHIBITORS OF MITOCHONDRIAL FUNCTION ON ROUS SARCOMA VIRUS REPLICATION AND MALIGNANT TRANSFORMATION. (E.) Schert, N. J. (U. Rochester Sch. Med. Dentistry, New York) and J. D. Hare. *Biochem Biophys Res Commun* 46(1):5-10, 1972.

The effects of chloramphenicol (CAP) and ethidium bromide (EB) on virus replication and oncogenic

transformation was studied in cultured chick embryo fibroblast cultures infected with Bryan high-titer strain of Rous sarcoma virus (RSV). Treatment of chick cells with 5-75 µg/ml CAP for 24 hr from 1-4 days after RSV infection caused minimal suppression of focus formation, but significantly inhibited virus production. The inhibition was directly proportional to CAP concentration. EB at µg/ml permanently prevented focus formation of RSV-infected cells when administered 24 hr prior to infection or within 48 hr after infection. The possibility of a nonspecific effect by EB on cell division was eliminated; EB had no effect on virus production. These results suggest that RSV replication in, and oncogenic transformation of, infected chick embryo fibroblasts depends on a function(s) mediated by mitochondria.

3772 TRANSFORMATION OF A RAT EPITHELIAL-LIKE CELL LINE BY MURINE SARCOMA VIRUS. (E.)

Bomford, R. (Imperial Cancer Res. Fund Labs., London, England) and I. B. Weinstein. *J Nat Cancer Inst* 49(2):379-386, 1972.

The transformation of a stable epithelial-like Sprague-Dawley rat liver cell line (RL) by the Harvey strain of murine sarcoma virus (MSV-H) was studied. Two to three days after infection, cells began to round up and detach from the culture surface. The remaining cells assumed a fibroblastic appearance and grew in piled-up foci. After two transfers, transformed cells were cloned in soft agar. Four clonal lines were established consisting of two types of cells: one releasing virus immunologically similar to MSV-H, and the other releasing no virus that could be detected by virus focus assay or by ³H-uridine labeling. The sarcoma virus genome could, however, be rescued from nonvirus-producing cells by superinfection with Moloney leukemia virus. Progressively growing, metastasizing sarcomas were produced by s.c. injection of nonvirus-producing cells into newborn Sprague-Dawley rats. Nonvirus-producing cells had an unaltered karyotype and were negative in immunodiffusion tests for murine leukemia virus antigens.

3773 DUAL INFECTION OF A HUMAN LYMPHOBLASTOID CELL LINE WITH EPSTEIN-BARR VIRUS AND RAUSCHER LEUKEMIA VIRUS. (E.) Niyoshi, I. (Okayama U. Med. Sch., Japan), H. Hasegawa, T. Tsubota, S. Irino and K. Hiraki. *Gann* 63(3):395, Plate XLIII, 1971.

A lymphoblastoid cell line (OUMS-11a) established from a patient with a neurologic disorder was infected in the 59th passage with Rauscher leukemia spleen extract. Examination of cells by electron microscopy at 71, 104, and 147 days (14th, 22nd and 32nd passages, resp.) revealed numerous immature and mature C-type particles in extracellular spaces, in intracytoplasmic vacuoles and budding from cell membranes. In addition, passage 32 cells also had

intracytoplasmic immature Epstein-Barr virus particles. Both infected and uninfected cultures contained Epstein-Barr virus capsid antigen-positive cells as shown by indirect immunofluorescence. I.p. inoculation of infected culture materials into newborn and weanling BALB/c mice failed to produce signs of illness. These results show that persistent infection of Epstein-Barr virus-bearing lymphoblastoid cells with Rauscher leukemia virus does not result in disappearance of the Epstein-Barr particles, as previously reported.

- 3774 PRESENCE IN HUMAN BREAST CANCER OF RNA HOMOLOGOUS TO MOUSE MAMMARY TUMOUR VIRUS RNA. (E.) Axel, R. (Inst. Cancer Res., Coll. Phys. Surg., Columbia U., New York, N.Y.), J. Schlom and S. Spiegelman. *Nature* 235(5332):32-36, 1972.

Hybridization experiments were conducted using purified mouse mammary tumor virus (MMTV)-directed DNA and purified RNA from human breast neoplasms. DNA-RNA hybrids were detected by isopycnic separation in Cs_2SO_4 gradients. Six to 17% of MMTV ^3H -DNA hybridized to RNA from human malignant breast tumors. Attempts to anneal MMTV-DNA to RNA from normal breast tissue or from fibrocystic disease tissue were unsuccessful. Of the 29 malignant breast tumors tested, 67% gave significantly positive responses. Hybridization of MMTV-DNA was specific for RNA from breast malignancies. No positive results were obtained with any human leukemias or sarcomas. Breast tumor RNA was likewise specific for MMTV-DNA; no annealing occurred with avian myeloblastosis virus-directed DNA.

- 3775 CHRONOLOGICAL APPEARANCE OF ALKALINE PHOSPHATASE ACTIVITY IN VIRUS-INDUCED THYMIC LYMPHOMAS OF C57BL/6 MICE. (E.) Wilson, K. J. (Dept. Biophys., Weizmann Inst. Sci., Rehovot, Israel), H. Neumann and N. Haran-Ghera. *Cancer Res* 31:1702-1705, 1971.

Homogenates of thymus, mesenteric lymph nodes, spleen, liver and kidney were assayed by a spectrophotometric procedure for alkaline phosphatase (APase) activity at different times during leukemogenesis in male C57BL/6 mice. Mice received intrathymic injection of one of two radiation leukemia viruses: a virus that produces a lymphoma incidence of 80-100% after inoculation when followed by whole body x-irradiation (Passage 127) and a virus that induces lymphatic leukemia in 80-100% of inoculated mice without irradiation (Passage 136). Increased APase levels were observed only in thymic homogenates prior to lymphoma development (at about nine wk). APase activity did not increase in the other tissues until after dissemination of the disease. APase activity did not increase if animals were inoculated with Passage 127 without further exposure to x-irradiation. Passage 127 virus remained viable in thymic tissue for several months suggesting that neoplastic transformation of

thymocytes or the proliferation of neoplastic cells was directly responsible for the increased enzyme activity.

- 3776 SPECIFIC ORIGIN IN SV40 DNA REPLICATION. (E.) Nathans, D. (Johns Hopkins U. Sch. Med., Baltimore, Md.) and K. J. Danna. *Nature New Biol* 236(68):200-202, 1972.

A model which predicts that replication of SV40 DNA begins at a specific site was tested by analyzing ^3H -thymidine pulse-labeled SV40 DNA segments by polyacrylamide gel electrophoresis. Labeled replicating SV40 DNA and newly completed DNA were reproducibly digested into 11 fragments by *H. influenzae* restriction nuclease, and the extent of label in each fragment was measured. The results conformed to the predictions of the model and indicated that SV40 DNA synthesis began at or near fragment C and ended at or near fragments G and B. It was estimated that less than five minutes was required to replicate a complete molecule of SV40 DNA. These "completed" DNA molecules sedimented as mature covalently closed, circular 21S particles in neutral sucrose gradients, indicating that there was not a long delay in the maturation of SV40 DNA.

- 3777 EARLY STIMULATION OF DNA SYNTHESIS IN CHICK FIBROBLASTS INFECTED BY AVIAN MYELOBLASTOSIS VIRUS. (E.) Harel, J. (Inst. Gustave-Roussy, Villej France), F. Lacour and T. Huynh. *Virology* 47(1):244-246, 1972.

^3H -thymidine incorporation into DNA of avian myeloblastosis virus (AMV)-infected chick fibroblast cultures was analyzed by CsCl equilibrium centrifugation. In the early period after incubation of cells with AMV from blood plasma of infected chicks, incorporation of ^3H -thymidine into DNA was 1.92 to 3.37 times the incorporation into DNA of noninfected cells. This difference became relatively negligible after labeling for 24 hr. The stimulation of incorporation into DNA was attributed to AMV per se since purified virus had a similar effect, and heat-inactivated virus had practically no effect. DNA from cells newly infected with AMV and the same buoyant density as and contained a percentage of total cellular radioactivity comparable to that of noninfected cells. It was concluded that a transitory enhancement of cellular DNA synthesis is one of the preliminary events in the course of AMV infection of chick fibroblasts.

- 3778 DETECTION OF AVIAN TUMOR VIRUS-SPECIFIC NUCLEOTIDE SEQUENCES IN AVIAN CELL DNAs. (E.) Yarmus, H. E. (U. California, Sch. Med., San Francisco), R. A. Weiss, R. R. Friis, W. Levinson and J. M. Bishop. *Proc Nat Acad Sci* 69(1):20-24, 1972.

The effect of chick embryo DNA on reassociation

kinetics of labeled double-stranded DNA produced by RNA-dependent DNA polymerase from Rous sarcoma virus (RSV) was used to measure virus-specific nucleotide sequences in normal and transformed cells. Fifty percent reassociation (half-Cot) values indicated the presence of multiple copies of viral nucleotide sequences in DNA from normal chick embryos, RS-induced chicken wing sarcomas and *in vitro* RSV-transformed cells. Multiple copies were also detected in DNA from cells harboring Rous associated virus (RAV-O) and in cells positive for viral group-specific antigen (gs⁺); they were not present in HeLa cells or salmon-sperm DNA. There were no significant differences between viral nucleotide sequences in transformed and untransformed cells or between sequences in gs⁺ and gs⁻ cells. Quail embryo cells, which were not gs⁺ and lacked RAV-O, also contained nucleotide sequences homologous to RSV, DNA and RAV-O DNA. The results suggest that viral genes may be present in normal cells.

3779 CHROMOSOMAL STUDIES OF SELECTED CELLS: THE V- CELL OF RAUSCHER'S MURINE LEUKEMIA.

(E.) Egozcue, E. (Inst. Biol. Fund., Autonomous U. Barcelona, Spain). *Ann Genet (Paris)* 15(1):25-28, 1972.

Chromosome studies were conducted on lymphocytic virus-induced cells (V-cells) obtained from blood samples from leukemic mice infected with Rauscher virus. Most of the 155 V-cell metaphase figures observed had a normal complement of 40 chromosomes. Only 6.6% were aneuploid. No structural anomalies were seen and the karyotype of the V-cells was consistent with the normal mouse karyotype. The number of gaps was within normal limits. These results do not agree with previously published findings indicating a significant percentage of aneuploidy and abnormal karyotypes in mouse leukemic spleen cells.

780 CELL FREE TRANSMISSION OF A PLASMOCYTOMA TO VARIOUS STRAINS OF ADULT MICE. (E.)

edio, G. (Inst. Path. Anatomy, U. Zurich, Switzerland) and J. R. Ruttner. *Europ J Cancer* 7(5):389-396, 1971.

A new "double inoculation" method is described for the production of a potent cell-free extract capable of transmitting the mesenteric HIPA-plasmacytoma. It is based on the assumption that HIPA ascites tumor is a more susceptible substrate for virus replication than normal tissue. Initially, tumor cells were inoculated i.p. into BALB/c mice. This was followed in two days by i.p. injection of cell-free HIPA tumor ultracentrifugate. After five to seven days, an ultracentrifugate prepared from the ascites cells of these mice was injected into other preinoculated mice. This procedure was repeated a total of seven times and resulted in an increased oncogenic potency of the ultracentrifugates in isogenic BALB/c mice. Tumor ultracentrifugates prepared from "double inoculated" mice were used to start two serial cell-free plasmacytoma cell lines in BALB/c mice. Tumors

developed after a latent period of three to five wk in 62 to 85% of the animals. Examination of these plasmacytomas by electron microscopy revealed the presence of intracellular type A and extracellular type C particles. The ultracentrifugates retained their oncogenic potential after freeze-thawing but lost it following millipore filtration. Ultracentrifugates of the two cell-free transmission lines produced mesenteric plasmacytomas following i.p. injection into allogenic adult C57Bl, ICR, C3H, DBA and AKR mice. Xenogenic transmission to rats and hamsters was unsuccessful.

3781 HERPESVIRUSES FROM THE OWL MONKEY (*AOTUS TRIVIRGATUS*). (E.) Barahona, H. H.

(Harvard Med. Sch., Southborough, Mass.), M. D. Daniel, L. V. Melendez, N. W. King, C. E. O. Fraser and F. G. Garcia. *J Nat Cancer Inst* 49(1):219-224, 1972.

Seven viral isolates obtained from cultured owl monkey cells which produced Cowdry type-A intranuclear inclusions in cultures stained with H and E were studied. Five came from animals that had never been used in experiments. Of the other two, one originated from a monkey inoculated with an *H. saimiri* filtrate and the second from a monkey inoculated with a squirrel monkey isolate which was not neutralized by *H. saimiri* antisera. None of the cultures infected with these viruses showed any type of cytoplasmic inclusion. Primate cell cultures were most susceptible to these viruses. Most of the isolates grew best in kidney cultures from owl monkey, Central American squirrel monkey and cebus monkey. Only two isolates multiplied in whole human embryo, rabbit kidney or goat cells. Acridine orange staining of infected cells and studies using 5-bromodeoxyuridine indicated that all seven viruses contained DNA. Electron microscopic observations revealed typical herpesvirus particles in infected cells. Preliminary serological studies indicated that, with one exception, the isolates were not related antigenically to known members of the herpesvirus group. The seventh isolate proved to be a strain of *H. tamarinus*. The isolates did not appear to be antigenically related to one another; however, potent antisera against some of these isolates were difficult to prepare. After preliminary grouping of these isolates, it was concluded that the owl monkey is the reservoir host for two or possibly three herpesviruses of its own.

3782 RIFAMYCIN DERIVATIVES STRONGLY INHIBITING RNA+DNA POLYMERASE (REVERSE TRANSCRIPTASE) OF MURINE SARCOMA VIRUSES. (E.) Gurgo, C. (St.

Louis U. Sch. Med., Mo.), R. Ray and M. Green. *J Nat Cancer Inst* 49(1):61-80, 1972.

One hundred and eighty rifamycin SV and B derivatives were screened for their ability to inhibit RNA+DNA polymerase (reverse transcriptase) of murine sarcoma viruses--Moloney and Harvey (MSV-M and MSV-H). Incorporation of ³H-TTP into acid insoluble material

in an *in vitro* assay mixture was used to determine enzyme activity. Sixteen of the derivatives were moderately active, inhibiting viral enzyme at a concentration of 20 µg/ml. Nine compounds showed a high degree of inhibition at concentrations between 5-20 µg/ml. The inhibitory activity of all 3-substituted derivatives correlated well with the size of the substituted side chain. With one exception, 3,4 substituted and 4-deoxy 3,4-substituted rifamycin SV derivatives, rifamycin B 4-substituted derivatives and four streptovaracin derivatives were all inactive.

- 3783 OBSERVATIONS ON THE DETAILS OF ULTRASTRUCTURE OF A SERIES OF TYPE C VIRUSES. (E.) Dalton, A. J. (Natl. Cancer Inst., Bethesda, Md.). *Cancer Res* 32:1351-1353, 1972.

Budding type C virions of murine leukemia virus (Moloney or Rauscher; MLV-M or MLV-R) grown in mouse or human cells, and of feline leukemia virus (FLV) grown in cat or human cells were studied by high-resolution electron microscopy. The virions differed from those growing from ESP-I cells, the human line that produces C type virus. Budding virions in two ESP-I lines, whether fixed in chrome-osmium or in glutaraldehyde, were characterized by a clear distinction between the intermediate layer and the envelope, with no clear separation between the inner boundary of the intermediate layer and the inner part of the nucleoid. In contrast, budding MLV-M and MLV-R virions had an intermediate layer which was thick (about 100 Å) compared to that of virions in the ESP-I cells and which was obviously separate from both the envelope and the inner part of the nucleoid. The intermediate layer of FLV virions, although thinner (about 50 Å) than in mouse virions, was also clearly distinguishable from both the envelope and the inner part of the nucleoid. The use of chrome-osmium at some stage was necessary to demonstrate these differences. These results support the view that the structure and interrelationships of the intermediate layer of developing type C virions are specific for the animal species in which they originate and are viral-genome directed. They also support the view, based on biochemical evidence and contradicted by immunological evidence, that the virions of ESP-I are not of mouse origin.

- 3784 DETECTION OF ANTIGENS OF THE MOUSE MAMMARY TUMOR (MTV) AND MURINE LEUKEMIA VIRUS (MuLV) IN CELLS OF CULTURES DERIVED FROM MAMMARY TUMORS OF MICE OF SEVERAL STRAINS. (E.) Hilgers, J. (U. Texas M.D. Anderson Hosp. Tumor Inst., Houston), W. C. Williams, B. Myers and L. Dmochowski. *Virology* 45(2):470-483, 1971.

Cultured cells from eight mammary tumors of BALB/c, (C57BL x Af)_{F1}, and RIII/Dm mice were reacted with each of three anti-mammary tumor virus (MTV) antisera prepared in rabbits, three anti-murine leukemia virus (MuLV) antisera prepared in rats, or one anti-

feline leukemia virus antiserum prepared in rabbits. Cells contained MTV particles (MTV+ cells) or MuLV particles (MuLV+ cells), or lacked either or both particles (MTV- or MuLV- cells). Indirect immunofluorescence (IF) tests were used to detect anti-MTV and anti-MuLV antigens within cells, and mixed hemadsorption reaction tests (MHA) were used to detect anti-viral surface antigens. MTV- mammary tumor cells showed weak reactions or no reaction with anti-MTV sera in IF and MHA tests. MTV+ cells showed MHA titers as high as 1:1024 with anti-MTV antisera. When anti-MTV sera were tested in IF with either MuLV+ or MuLV- cells, no staining was seen. Some MTV- cells were positive for MuLV antigens in MHA and IF. One line was positive for MTV as well as MuLV antigens in both MHA and IF tests. Of five cell lines from BALB/c mammary tumors, three were positive for anti-MuLV antigens in MHA as well as IF tests. Type C virus particles were seen in all these three cell lines. No MTV antigen was found by IF in one line with an anti-MTV serum, but MHA showed some cells of this line positive for MTV antigen with the same anti-MTV serum. IF reactions were localized in cell cytoplasm; no nuclear fluorescence for MuLV and MTV antigens was observed. The MuLV-gs3 antigen (an antigen shared by mammalian leukemia-sarcoma viruses) was found by IF in tumor cells producing C-type particles. MuLV-gs1 and MuLV-gs3 antigens were not seen in MTV+ cell lines which were MuLV-. Cell lines positive for MTV and/or MuLV antigens by IF were also positive by MHA. Anti-MuLV-gs1 and anti-MuLV-gs3 antisera gave positive IF reactions with MuLV+ cells but negative MHA reactions with an MuLV+ cell line which produced C-type particles.

- 3785 CYTOCHEMISTRY, CYTOGENETICS AND ULTRASTRUCTURE OF HAMSTER TUMOUR CELLS CARRYING MOUSE SARCOMA VIRAL GENOME (HT-1 CELLS). (E.) Karpas, A. (Dept. Med., U. Cambridge, England), J. Cawley, E. Tuckerman, R. Flemans and F. G. J. Hayhoe. *Brit J Cancer* 24(4):779-788, 1971.

An HT-1 cell line, derived from a hamster fibrosarcoma, was found to carry the murine sarcoma virus genome although it did not initially produce the virus. Cytochemical tests with periodic acid-Schiff staining indicated that the highly pleomorphic HT-1 cells contained glycogen. HT-1 cells were positive for acid phosphatase, negative for alkaline phosphatase. Karyotype analyses revealed that HT-1 cells were aneuploid with chromosome numbers fluctuating around triploidy (though no true triploids could be found). Many cells contained a very large telocentric marker chromosome which was absent from normal hamster cells; more than half of tested HT-1 cells contained marker fragments or minute chromosomes. A clone was isolated which lacked these markers. No C-type virus particles were seen in HT-1 cells examined under an electron microscope, but some cells contained spiked, 700 Å particles which resembled viruses. Nuclei contained "dense bodies" or "nuclear bodies" such as had been observed in nuclei of virus-induced tumor cells. Some nuclei lacked chromatin aggregates.

- 3786 HERPES SIMPLEX INFECTIONS IN HEMATOLOGIC MALIGNANCIES. (E.) Muller, S. A. (Mayo Clin., Rochester, Minn.), E. C. Herrmann, Jr. and R. K. Winkelmann. *Amer J Med* 52(1):102-114, 1972.

Patients with hematologic malignancies are shown to be especially vulnerable to development of herpes simplex virus (HSV) infections affecting skin and mucous membranes. At the Mayo Clinic (1960-69) twenty patients (median age fifty-five) with various hematologic malignancies had HSV infections; the small number of cases reported probably being low because HSV infection is rarely considered. In eleven of thirteen patients so studied, HSV was isolated from skin and mucous membrane lesions, and HSV antibodies were found in serum of eight patients tested. Study of the serum gamma globulin and immunoglobulin levels showed no relation to severity of HSV infection. A chronic localized herpetic ulcer (herpes phagedena) seen as a large necrotic ulcer particularly around lips, nose and eyelids of patients not acutely ill was distinctive to the study; idoxuridine ointment (0.5%) topically applied was beneficial in healing the lesions, although it is not effective in treating common recurrent HSV infection.

- 3787 SPECIFIC INHIBITION OF DNA-POLYMERASES FROM RNA TUMOR VIRUSES BY SOME NEW DAUNOMYCIN DERIVATIVES. (E.) Chandra, P. (Inst. Therap. Biochem, U. Frankfurt, W. Germany), F. Zunino, A. Götz, D. Gericke and R. Thorbeck. *FEBS Letters* 21(3):264-268, 1972.

The effects of daunomycin, an anthracycline group antibiotic, and several of its structural analogues on the DNA-polymerase activity and tumorigenic ability of Friend leukemia virus (FLV), murine sarcoma virus-Moloney (MSV-M) and Rous sarcoma virus (RSV), were studied. Purified FLV and RSV suspensions were incubated (1 hr, 37 C) with antibiotic (50 µg/ml) and then injected i.p. into mice and chickens, resp. Daunomycin and adriamycin significantly prolonged the survival time of the infected mice and chickens. This effect was correlated with an inhibitory effect of both antibiotics on reverse transcriptase activity in MSV-M, FLV and RSV, as measured by incorporation of ³H-TMP into DNA. Dihydro daunomycin had an intermediate effect in both prolonging survival time and inhibiting reverse transcriptase. The derivatives substituted in the amino sugar moiety (N-guanidine- and N-acetyl-daunomycin) were ineffective in prolonging survival of both animals. The N-acetyl derivative was also ineffective in inhibiting reverse transcriptase in MSV-M and FLV, but did show moderate inhibition in RSV. Similar differences in inhibitory effects of daunomycin and its derivatives on reverse transcriptase were observed when synthetic templates were used. It is concluded that substitutions in the amino sugar moiety, especially N-acetylation, inhibit the antitumor activity of, and influence the inhibition of reverse transcriptase by, daunomycin.

- 3788 THE 3'-TERMINAL NUCLEOSIDES OF THE HIGH MOLECULAR WEIGHT RNA OF AVIAN MYELOBLASTOSIS

VIRUS. (E.) Stephenson, M. L. (Huntingdon Mem. Hosp., Harvard U., Boston, Mass), L. S. Wirthlin, J. F. Scott and P. C. Zamecnik. *Proc Nat Acad Sci USA* 69(5):1176-1180, 1972.

RNA was purified from avian myeloblastosis virus (AMV) BAI Strain A, isolated from chicken plasma from infected chicks and from myeloblast tissue cultures, and fractionated by sucrose density centrifugation. The 3'OH terminal nucleosides of various fractions were analyzed by thin-layer cellulose chromatography after periodate oxidation and tritiated borohydrate reduction of the RNA alkaline hydrolysates. The 3'OH-terminal nucleoside from 60-70S AMV-RNA, 35S AMV-RNA (obtained by heating 60-70S RNA), tRNA and 4S RNA (derived from heated 60-70S RNA) fractions was adenosine. By the borohydrate method, the molecular wts for the 60-70S and the 35S RNA fractions were similar (2×10^6), which was consistent with a suggested subunit structure for 60-70S material found by others.

- 3789 VIRUS PARTICLES IN SJL/J MOUSE DISEASE. (E.) Okano, H. (Fac. Med., Kyushu U., Fukuoka, Japan), M. Koga and H. Otsuka. *J Nat Cancer Inst* 49(2):485-491, 1972.

Lymphatic tissues from 26 strain SJL/J mice, 1-443 days old, were examined by electron microscopy. Virus particles were rare in newborn or young mice, which are apparently free from lymphomatous lesions. However, in the lymphatic tissues of animals older than 313 days, type C-virus particles were abundant, and lymphoid hyperplasia and reticulum cell neoplasia were seen (Dunn's type-B lesion). Characteristically, numerous type-C virus particles were localized between irregularly shaped cisternae in the cytoplasm of peculiarly shaped giant cells. Some budding and immature type-C particles, associated with mature type-C particles, were also in the cisternae. The presence of these abundant type-C virus particles within the lymph node may be closely related to reticulum cell neoplasia.

- 3790 RIFAMYCIN ANTIBIOTICS: INHIBITORS OF RAUSCHER MURINE LEUKEMIA VIRUS REVERSE TRANSCRIPTASE AND OF PURIFIED DNA POLYMERASES FROM HUMAN NORMAL AND LEUKEMIC LYMPHOBLASTS. (E.) Yang, S. S. (Bionetics Res. Labs., Bethesda, Md.), F. M. Herrera, R. G. Smith, M. S. Reitz, G. Lancini, R. C. Ting and R. C. Gallo. *J Nat Cancer Inst* 49(1):7-25, 1972.

Two hundred and one rifamycin derivatives were screened for inhibitory effects against partially purified human normal and leukemic lymphocyte and murine leukemia virus DNA polymerases using poly d(AT) and endogenous 70S RNA as templates, resp. The derivatives, obtained by substitution at position 3 and/or 4 of the naphthalene ring, were classified on the basis of structure into eight groups. Compounds producing greater than a 50% inhibition of incorporation of ³H-TTP into acid insoluble material (30 min, 250 µg/ml for leukemic and 50 µg/ml for viral polymerase) were

classified as active. Although few general correlations were found between structure and inhibitory capacity, most 3-hydrazonomethyl derivatives were active, whereas only one of 16 4-deoxy derivatives showed activity. Ten active compounds were further studied for selective activity against the endogenous reverse transcriptase activity of Rauscher leukemia virus. Under all conditions tested, 3-(2,4-dinitrophenylhydrazonomethyl) rifamycin SV and 3-piperazinoiminomethyl rifamycin SV (N-demethylrifamycin) inhibited viral polymerase to a greater extent than did cellular polymerase I or polymerase II. Both compounds inhibited normal polymerase I more strongly than polymerase II. Both preferentially inhibited leukemic cellular polymerase II over normal cellular polymerase II. Because these compounds preferentially inhibited viral reverse transcriptase and leukemic DNA polymerase II, they may be of clinical interest as potential antileukemic agents.

3791 SEQUENTIAL CHANGES IN SPLEEN CELL CHROMOSOMES DURING FRIEND VIRUS LEUKEMIA. (E.)

Elliott, S. C. (Dept. Biol., Drake U., Des Moines, Iowa), R. M. Helm and M. E. Myszewski. *Cancer Res* 32(4):776-780, 1972.

Sequential changes in spleen cell karyotype were studied in 76 female BALB/c mice at weekly intervals for five weeks following i.p. injection of serial dilutions of Friend leukemia virus (FLV). Uninfected mice served as controls. All infected mice exhibited hyperplasia of the erythroid elements of the spleen, with resultant progressive splenomegaly, which increased in proportion to virus dose. Although polyploid cells were found after infection with all doses of virus, their frequency did not correlate statistically with time after infection, virus dose, or an interaction of the two. A total of 0.9% of 2149 infected metaphase cells examined showed a hyperdiploid number of 41 chromosomes. This number was not clustered at any stage of the disease and was not higher than that of control mice. The number of abnormal cell configurations in infected animals did differ significantly from controls throughout the disease process, but no single abnormal diploid number predominated. A significant correlation was found between the number of secondary chromosomal constrictions and the progression of the disease. As spleen weight increased, the number of secondary constrictions per metaphase figure increased. There was an inverse relationship between increased spleen weight and the number of normal diploid cells lacking secondary constrictions. Since an increased number of these secondary constrictions appeared early in the disease process, even with low FLV doses, this change was considered to have significant mutational importance.

3792 REPLICATION OF VIRAL DEOXYRIBONUCLEIC ACID AND BREAKDOWN OF CELLULAR DEOXYRIBONUCLEIC ACID IN EPSTEIN-BARR VIRUS INFECTION. (E.)

Nonoyama, M. (U. North Carolina Sch. Med., Chapel Hill) and J. S. Pagano. *J Virol* 9(4):714-716, 1972.

Raji cells (a nonproductive line of Burkitt's lymphoma) were infected with Epstein-Barr virus (EBV). The replication of viral DNA, as followed by hybridization with EBV-specific complementary RNA, and the fate of cellular DNA was studied. Incorporation of ³H-thymidine into acid-insoluble material was significantly suppressed by 12 to 18 hr after infection. Viral DNA replication started around 12 hr and was most active between 18 and 30 hr. The quantity of EBV DNA formed reached 1,000 genome equivalents per cell. Nonetheless, little, if any, virus was formed, as based on the appearance of viral capsid antigen. Alkaline sucrose gradient centrifugation of DNA from cells prelabeled with ¹⁴C-thymidine, and then labeled with ³H-thymidine after virus infection, showed that about 80% of both preexisting and newly synthesized cellular DNA was degraded to 20-30S fragments. Results also indicated that EBV infection suppressed cellular DNA synthesis as compared with uninfected cells.

3793 EPIDERMODYPLASIA VERRUCIFORMIS AS A MODEL IN STUDIES ON THE ROLE OF PAPOVAVIRUSES IN ONCOGENESIS. (E.) Jablonska, S. (Warsaw Sch. Med., Poland), J. Dabrowski and K. Jakubowicz. *Cancer Res* 32(3):583-589, 1972.

Results of a study showing that papovavirus is a causative factor in the verrucous lesions in epidermodysplasia verruciformis (EV) and also in the initiation of the morbid process are reported. The study involved a 30-year-old female patient in whom lesions with evident papovavirus first developed at age five after contact with the crushed common wart of a brother. Histology of specimens from the dorsum of the patient's hands was typical of flat warts in EV; some but not all forehead specimens showed atypia (Bowen's disease, invasive Bowen's carcinoma, and changes of the senile keratosis type). The virus was demonstrable by electron microscopy as crystalloid structures in verrucous lesion nuclei. Bowen's disease type lesions from the forehead showed enlarged nuclei with abnormal distribution of chromatin and other atypical signs. In forearm lesions with virus-containing cells, chromatin was less abundant and showed peripheral distribution. Negative staining showed that the shape and size of the virus capsid were characteristic of papovaviruses. Heteroinoculation was successful in only one of eight test subjects. Transmission of the viral infection indicates that the virus is responsible for the verrucous lesions in EV and consequently is pathogenic.

3794 PRESENCE OF DNA IN ONCOGENIC RIBOVIRUSES. (Fr.) Emanoil-Ravicovitch, R. (Saint-Louis Hosp., Paris, France). *Pathol Biol (Paris)* 19(21-22):1003-1006, 1971.

In 1970 several research teams found DNA inside Rous

sarcoma virus in chickens, avian myeloblastosis virus in chickens, and Maloney mouse sarcoma by labeling with ^{14}C -uridine and ^3H -thymidine. It was ascertained that the DNA is almost certainly not an artefact, but a true constituent of the 3 viruses. The DNA was sensitive to pancreatic DNase, but resistant to RNase and hydrolysis. Although the sedimentation coefficient (7S), determined in a sucrose gradient, revealed a population which was relatively homogeneous in size, two distinct populations were isolated by density gradient. It is estimated that intraviral DNA accounts for approximately 2.5% of the total nucleic acids extracted from virions. Electrophoretic studies on polyacrylamide gel with nucleic acid labeled with ^3H -thymidine disclosed that DNA was not linked to RNA 65S by a covalent bond. The density of RNA 65S was between 1.61-1.64 g/cm³ and that of DNA, 1.423 g/cm³. This slight shift to a higher density indicates there is some complementarity between intraviral DNA and RNA, but whether DNA is necessary to render a virus infectious remains to be shown.

3795 MARKER BAND IN ONE CHROMOSOME 14 FROM BURKITT LYMPHOMAS. (E.) Manolov, G. (Inst. Genetics, U. Lund, Sweden) and Y. Manolova. *Nature* 237(5379):33-34, 1972.

Chromosome banding patterns were studied in preparations from six Burkitt lymphoma tumor biopsies and nine Burkitt lymphoma tumor lines stained with Giemsa or treated with quinacrine mustard (QM). Both staining techniques consistently revealed an extra band in one homologue of D group chromosome pair No. 14 in ten of the 12 tumors. In three tumors where both biopsies and cultures were examined, results were consistent in the two types of samples. The extra band was found at the end of the long arm and was similar to the normal fluorescing bright band (q7') also found in that area. The extra band, however, was often less luminescent with QM and more weakly-stained with Giemsa, as well as being somewhat narrower than the normal q7'. This marker was much more consistently present than were other markers (e.g., the secondary constriction on chromosome No. 10) normally associated with Burkitt lymphoma.

3796 GLYCOLIPID SYNTHESIS IN NORMAL AND VIRUS-TRANSFORMED HAMSTER CELL LINES. (E.) Takiyama, H. (Dept. Biol., Massachusetts Inst. Tech., Cambridge), S. K. Gross and P. W. Robbins. *Proc Nat Acad Sci USA* 69(4):872-876, 1972.

Glycolipid synthesis in several clones from the NIL embryonic hamster cell line, which differ in morphology, saturation density and glycolipid patterns, was studied. No correlation was found between saturation density and complexity of the glycolipid pattern. The clone with the highest saturation density was the only one to show the complete set of glycolipids [monohexosyl ceramide (GL-1), dihexosyl ceramide (GL-2), trihexosyl ceramide (GL-3), globoside (GL-4), Forssman antigen

(GL-5), and hematoside (G_{M3})] previously found in NIL 2 cells. All untransformed NIL clones showed density-dependent increases in GL-3, GL-4, GL-5 and G_{M3}, which had been prelabeled with ^{14}C -palmitate and identified by thin-layer chromatography. The high-saturation-density clone showed increases in GL-3, GL-4 and GL-5, but not G_{M3}. One line which contained only G_{M3} showed an increase in that moiety at confluence. Cells transformed by hamster sarcoma virus or polyoma virus contained only GL-1, GL-2, and G_{M3} and showed no density-dependent effect on these glycolipids. Chemical measurement of glycolipid changes during density-dependent inhibition confirmed the results obtained from the radioactive assays.

3797 VIRAL AND IMMUNOLOGIC STUDIES OF HUMAN NEOPLASMS. (E.) Malmgren, R. A. (No affiliation) and D. L. Morton. *Pathol Annu* 1:63-81, 1971.

The possible application of immunologic techniques to diagnostic or detection methods is reviewed. Evidence presented for a viral etiology of tumors includes discussion of transformation experiments which demonstrate a cancer proneness in individuals from whom fibroblasts are derived. Electron microscopic studies carried out in conjunction with immunologic techniques have enabled identification of a virus which permits clearer insight into the virus' relationship to a specific neoplasm. In addition, tumor specific antigens have been successfully demonstrated and distinguished from normal antigens in several cases. Cellular immunity, lymphocyte transformation, cell-mediated cytotoxicity, radio-immunodiffusion methods and immunotherapy are also discussed. The ultimate possibility of detecting a high cancer risk population through the use of currently developing laboratory procedures is seen as a reality in the near future.

3798 THE RESPONSE OF BHK21 CELLS TO INFECTION WITH TYPE 12 ADENOVIRUS: VI. SYNTHESIS OF VIRUS-SPECIFIC RNA. (E.) Raska, K., Jr. (Rutgers Med. Sch., New Brunswick, N.J.) and W. A. Strohl. *Virology* 47:734-742, 1972.

The sequences of adenovirus type 12 (Ad12) genomes transcribed during the abortive infection of GL-arrested BHK21 cells were studied. RNA-DNA hybridization-competition experiments demonstrated that newly synthesized specific RNA corresponded to as much as 60% of those "early" (synthesized in the presence of cytosine arabinoside 18-19 hr post-infection) mRNA sequences which were transcribed in productively infected human embryonic kidney (HEK) cells. No "late" (synthesized 23-24 hr post-infection) Ad12 mRNA was detected in BHK21 cells. Comparison of Ad12-specific RNA sequences transcribed in Ad12-infected BHK21 cells and in Ad12-induced hamster tumor cells (HT₂) by hybridization-competition showed that HT₂ cells did not contain significantly greater amounts of Ad12-

specific RNA sequences than those present in Ad12-infected G1-arrested BHK21 cells. Under conditions of minimal background cellular DNA synthesis, DNA-DNA hybridization experiments did not detect synthesis of viral DNA in Ad12-infected BHK21 cells. Immunofluorescent staining experiments indicated that Ad12 capsid protein synthesis occurred with a frequency of not more than one in 10^4 infected cells.

- 3799 RNA-DEPENDENT DNA POLYMERASE IN VIRUSES AND CELLS: VIEWS ON THE CURRENT STATE. (E.) Gallo, R. C. (Natl. Cancer Inst., Bethesda, Md.). *Blood* 39(1):117-137, 1972.

The presence of an RNA-dependent DNA polymerase or reverse transcriptase has been found in every RNA oncogenic virus investigated, with the exception of some mutant viruses that have lost the ability to infect or transform normal cells. It is assumed that the role of the enzyme is to convert viral 70S RNA to a DNA copy allowing the viral genome to be inserted into host cell DNA. Nononcogenic viruses either contain no polymerase activity or an RNA-dependent RNA polymerase with the exception of the Foamy viruses which have been shown to contain reverse transcriptase. However, it is thought that this type of virus may eventually be shown to be oncogenic. A demonstration of the presence of a true reverse transcriptase in an isolated particle would strongly support the notion that the particle is an RNA virus and potentially oncogenic. The presence of a true reverse transcriptase (catalyzing synthesis of DNA from *pure single stranded natural RNAs*) in cells is more difficult to establish. The use of some synthetic templates such as the RNA-DNA hybrids poly rA.dT to detect the presence of reverse transcriptase has led to some confusion. Although reverse transcriptase has great affinity for these templates *they lack specificity*, i.e., virtually any DNA polymerase will use them. Thus, activity with these templates does not in itself indicate that reverse transcriptase is present. At this time there is no published definitive information demonstrating the presence of this enzyme in any normal cell. An unequivocal demonstration of its presence in a human tumor tissue would, therefore, appear to indicate that information from an RNA oncogenic virus may be present.

- 3800 SPONTANEOUS APPEARANCE OF CYTOPATHOLOGY AND RAT C-TYPE VIRUS (WF-1) IN A RAT EMBRYO CELL LINE. (E.) Bergs, V. V. (U. Miami Sch. Med., Fla.), G. Pearson, H. C. Chopra and W. Turner. *Int J Cancer* 10:165-173, 1972.

After two yr of culture, the WF-1 line of fibroblastic rat embryo cells, initiated from apparently normal embryos, manifested cytopathological changes which became more pronounced when bovine amniotic fluid was removed from the culture medium. Cellular changes appeared four to seven days after seeding of cells in fresh vessels and disappeared if WF-1 cells

were subcultured at three to four day intervals. Cytopathological changes included the development of foci of altered rounded and fusiform cells with dark prominent nuclei. Most of these cells were viable, but failed to multiply in new medium. C-type virus particles were seen in WF-1 cells both before and after cytopathological alterations became evident; particles budded from cell plasma membranes and were also seen extracellularly. Extracts of altered WF-1 cells produced no changes in cultured REL rat embryo cells. When C-type viruses in WF-1 culture supernatants were concentrated and banded on a sucrose gradient (buoyant density = 1.16 g/cm^3), an infectious virus of one TCID₅₀/10⁴ virus particles was seen. Concentrated banded virus particles produced foci of viable rounded cells in REL cultures; these foci resembled foci previously formed in REL by a C-type virus (BV-1) isolated from a chemically induced rat mammary tumor. Immune BV-1 serum neutralized WF-1 virus cytopathic activity in REL. WF-1 cells were negative when tested for properties characteristic of murine leukemia viruses (MuLV) (e.g., mouse gs-1 and gs-3 antigens and capacity to induce an XC reaction characteristic of MuLV). Inocula of $1.1-3.5 \times 10^6$ WF-1 cells produced fibrosarcomas in 90-100% of W/FU rats within five wk of inoculation. Fibrosarcomas produced by inoculation of WF-1 cells contained C-type particles.

- 3801 PERSISTENCE OF ROUS SARCOMA VIRUS IN TRANSFORMED NON-PERMISSIVE CELLS: MECHANISM OF VIRUS INDUCTION BY ASSOCIATION WITH PERMISSIVE CELLS IN THE ABSENCE OF SENDAI VIRUS. (E.) Vigier, P. (Radium Inst., Fac. Sci., Orsay, France). *Int J Cancer* 9(1):150-161, 1972.

BHK-21 hamster cells were transformed with Schmidt-Ruppin Rous sarcoma virus (RSV) or Bryan (RAV) RSV. The resulting transformed but nonpermissive cells (TNP), called RS2 and RB12, were grown together with permissive chick embryo cells (CE) and production of free virus (FV) and appearance of infective centers (IC) were observed. FV was induced in irradiated and nonirradiated mixtures of RS2 cells and CE. Schmidt-Ruppin RSV and IC were not induced when an anti-RAV antiserum was added to the cell mixtures. Production of RSV by association of TNP and CE appeared to result from reinfection of CE cells by RSV produced by the IC's. RSV was also produced in all of 11 RS2-derived subclones tested, indicating that the TNP RS2 cells carried at least one complete viral genome. IC's and FV were also seen when RB12 cells were mixed with CE. Initial IC's were presumably formed by fusion of TNP cells and CE cells. Transformed chicken cells appeared later, and arose from secondary infection of chicken cells. The number of focus-forming IC's recovered from RS2 subclones was always less than one per 10^3 cells. No such IC's were seen in two RS2 subclones from which FV could be recovered after Sendai virus-mediated fusion with CE cells. Even heterokaryon formation failed to remove the block of virus production in these subclonal TNP cells. FV was induced only by association of TNP and permissive CE cells. The results are thought to eliminate the possibility that FV is induced in TNP

by transfer of subviral determinants from TNP cells to CE cells, since virus production and secondary infection of CE cells were prerequisites for induction of FV.

3802 RNA OF RNA TUMOUR VIRUSES CONTAINS POLY A. (E.) Gillespie, D. (Gerontology Res. Ctr., Baltimore, Md.), S. Marshall and R. C. Gallo. *Nature New Biol* 236(69):227-231, 1972.

An assay involving the hybridization of radioactive polyuridylic acid (poly U) to nonradioactive virus RNA at high temperatures (35-40 C) was used to detect the presence of poly A tracts in oncogenic and nononcogenic viruses. The poly A content of RNA preparations from oncogenic viruses from avian, murine and primate sources ranged between 1 and 3% of the viral 70S genome. Polyacrylamide gel electrophoresis of the ³H-poly U-viral RNA hybrids indicated that they were larger than hybrids formed with RNA prepared from human blood lymphocytes. It was estimated that the RNA molecules isolated from the RNA tumor viruses examined contained between 300-900 nucleotide equivalents of poly A (1-3 tracts). Poly A was also detected in RNA from leukemogenic viruses and in RNA from a virus associated with mammary adenocarcinoma. In contrast, RNA preparations from most nononcogenic RNA viruses contained 25 to 50 times less poly A than RNA from oncogenic RNA viruses. Polio virus, a member of the picorna group, did contain a significant level of poly A. In those cases where poly A was observed in RNA from nononcogenic viruses, the tracts could be distinguished from those of tumor virus RNA by polyacrylamide gel electrophoresis. Hybridization of viral RNA with polyribocytidylic acid showed that although low levels of poly G are present in several RNA viruses, there is no correlation between poly G content and tumorigenicity.

3803 DETECTION OF RNA-INSTRUCTED DNA POLYMERASE AND HIGH MOLECULAR WEIGHT RNA IN MALIGNANT TISSUE. (E.) Gulati, S. C. (Coll. Physicians Surgeons, Columbia U., New York, N.Y.), R. Axel and S. Spiegelman. *Proc Nat Acad Sci USA* 69(8):2020-2024, 1972.

An RNA-DNA hybridization technique has been used to detect 70S RNA-directed DNA synthesis in mouse mammary carcinomas. Breast tumors excised from tumor-bearing Paris RIII mice were homogenized and fractionated according to a procedure designed to eliminate cellular nucleases, polymerases and RNA. Glycerol gradient centrifugation of the *in vitro* acid-insoluble tumor homogenate polymerase assay product showed a distinct virus-specific peak with a sedimentation coefficient of 70S, indicating the presence of viral RNA-directed DNA polymerase. No such activity was detected in homogenates of normal lactating breast tissue from tumor-free NIH Swiss mice. The ability to hybridize the ³H-labeled DNA product specifically to purified mouse mammary tumor virus (MMTV) RNA proved that the RNA-directed

DNA polymerase was of MMTV origin. The ³H-DNA product of the MMTV polymerase could be used to detect virus specific RNA in polysomal fractions from mouse breast tumor homogenates. No virus-specific RNA was detected in polysomal fractions from livers of tumor-free NIH mice.

3804 DETECTION OF HIGH-MOLECULAR-WEIGHT RNA IN PARTICLES FROM HUMAN MILK. (E.) Schlom, J. (Coll. Phys. Surg., Columbia U., New York, N.Y.), S. Spiegelman and D. H. Moore. *Science* 175(4021):542-544, 1972.

An assay developed to permit the simultaneous detection of reverse transcriptase and the 60S to 70S high-molecular-wt RNA unique to the oncogenic RNA viruses (oncornaviruses) was applied to particles isolated from human milk. Milk preparations were clarified by EDTA treatment and centrifugation. The pellet was suspended in NP40 and dithiothreitol and an endogenous reverse transcriptase reaction was carried out using ³H-TTP incorporation into DNA. The nucleic acids were then extracted and subjected to Cs₂SO₄ equilibrium gradient centrifugation. Fractions were collected and analyzed for acid-insoluble radioactive material. Under these conditions, the presence of ³H-DNA which sedimented as 60S-70S material indicated the presence of both reverse transcriptase and 60S-70S RNA. Numerous preparations of human milks were assayed and RNA:³H-DNA complexes were observed sedimenting at 67S. One milk preparation from a woman with a family history of breast cancer showed an excessively high peak of radioactivity in the 60S to 70S region. Milks from different women varied in enzyme content and milks from individual women differed from day to day. These effects could be due either to actual variation in the amounts of milk particles or to the variable presence of inhibitors. Inhibitors were implicated in at least one case in which no ³H-DNA:RNA 60S to 70S complex was observed when RIII mouse milk containing mouse mammary tumor virus (MMTV) was mixed with human milk. RIII milk processed alone produced such a complex. ³H-DNA in the 35S region was also found in assayed milks from nine of 20 women. A similar 35S complex has been observed in the assay of MMTV and other oncogenic RNA viruses.

3805 AN EXPERIMENTAL STUDY OF VIRUS LEUKEMIA IN CATS. (E.) Mackey, L. J. (Animal Leukaemia Res. Unit, U. Glasgow, Scotland), W. F. H. Jarrett, O. Jarrett and H. M. Laird. *J Nat Cancer Inst* 48(6):1663-1670, 1972.

Thirty-seven newborn cats were inoculated with feline leukemia virus (FeLV) obtained from a spontaneous feline alimentary lymphosarcoma. By 3.5 yr after inoculation, 13 cats had developed hematopoietic neoplasms, 13 had died from other causes and 11 remained alive. Some tumor-free cats showed thymic atrophy and lymphoid depletion. Among cats with tumors, there were four alimentary lym-

phosarcomas (latent period, ≤ 16 months), two thymic lymphosarcomas (latent period, > 2 yr), two multicentric lymphosarcomas (latent period, ≤ 16 months), four lymphoid leukemias (latent period, 1-33 months) and three myeloid leukemias (latent period, > 2 yr). The overall tumor incidence in all cats given FeLV was approximately 50%. No uninoculated cats developed advanced neoplasms. As shown by electron microscopy, virtually all 37 cats inoculated neonatally became infected with FeLV; some cats remained infected until adulthood without developing tumors. All tumor-bearing cats contained replicating C-type virus.

- 3806 DEMONSTRATION OF *HERPESVIRUS SAIMIRI*-ASSOCIATED ANTIGENS IN PERIPHERAL LYMPHOCYTES FROM INFECTED MARMOSETS DURING *IN VITRO* CULTIVATION. (E.) Falk, L. A. (U. Illinois Med. Ctr., Chicago), L. G. Wolfe, J. Hoekstra and F. Deinhardt. *J Nat Cancer Inst* 48(2):523-530, 1972.

Marmosets were inoculated with cell-free *Herpesvirus saimiri* (HVS) or with tumor cells from HVS-infected marmosets. Femoral venous blood was collected from infected marmosets and lymphocytes were separated out on Ficoll-Hypaque gradients. Lymphocytes were grown on suspension cultures or on vero monkey cells. Lymphocytes in fixed smears from suspension cultures and in vero cell coverslip cultures were tested by the indirect fluorescent antibody method for HVS and HVS-associated antigens at intervals up to 120 hr after initiation of cultures. No lymphocyte smears made immediately after initiation of culture with HVS-infected blood lymphocytes showed antigenicity, but 1-5% of cells seen in smears taken after 24 hr incubation were HVS antigen-positive. Smears prepared 48 and 72 hr after incubation did not show an increase in the number of antigen-positive cells. No HVS was recovered from supernatants or cell-free extracts of lymphocyte suspensions after cultivation up to 120 hr. HVS was recovered, however, from lymphocyte and vero cell cultures. HVS antigens were seen in vero cell cultures 24 hr after incubation of vero cells with HVS infected blood lymphocytes. It appeared that by 24 hr the HVS genome had been transferred to vero cells from infected lymphocytes.

- 3807 EXPERIMENTAL STUDIES BY TISSUE CULTURE OF A NEW MURINE LEUKOSIS VIRUS (ML. V). (E.) Hamazaki, Y. (Okayama U. Med. Sch., Japan), T. Murao and T. Murao. *Arch Geschwulstforsch* 39(1):8-23, 1972.

Ingestion of human malignant neoplasms by mice led to the isolation of a murine leukemia virus (ML. V) in 28 of 85 experiments. The ML. V was cultured on HeLa and L cells and established virus-carrying cell lines were produced. On HeLa cells, no change in morphology was seen immediately after inoculation with ML. V. Chromosome numbers in ML. V-bearing HeLa cells had a wider range in virus-free HeLa cells. A kind of "cell clasping" or phagocytosis was seen

in a few ML. V-infected HeLa cells. Cytopathic effect (CPE) was not seen in ML. V-infected cells, but a specific CPE was seen three to four days after establishment of ML. V in culture in L cells. Nuclear inclusion bodies were often seen in ML. V-carrying L cells. Infiltration of myeloid cells was observed in mice and rats inoculated with ML. V; there was also severe reticuloendotheliosis with granuloma in liver and spleen. ML. V showed a specific hemagglutinin response against rat red blood cells.

- 3808 ANTIGENIC PROPERTIES OF MURINE SARCOMA VIRUS-TRANSFORMED BALB/3T3 NONPRODUCER CELLS. (E.) Stephenson, J. R. (Natl. Inst. Hlth., Bethesda, Md) and S. A. Aaronson. *J Exp Med* 135(3):503-515, 1972.

BALB/c mice were inoculated with cells of a Kirsten murine sarcoma virus (MSV)-transformed subclone of BALB/3T3 clone A31 cells (subclone K-234) or Rauscher murine leukemia virus (MuLV)-transformed K-234 cells (K-234(R)). K-234 cells produced no detectable virus while K-234(R) cells produced MSV and MuLV. K-234 cells were more tumorigenic in inoculated mice than K-234(R) cells, suggesting that K-234(R) cells were more antigenic than K-234 cells. This supposition was supported by the finding that irradiation had little effect on growth of K-234 cells in recipients but enhanced growth of K-234(R) cells. Mice immunized with repeated injections of K-234(R) cells before challenge with these cells had reduced tumor incidence. In contrast, preimmunization with K-234 cells was not effective in protecting against K-234 cell challenge. Preimmunization with sonicated K-234(R) cells also protected mice against challenge with K-234(R) cells, but preimmunization with sonicated K-234 cells did not induce resistance to challenge with K-234 cells. Immunization of mice with rat cells did not protect against challenge with K-234 cells; immunization with UV-irradiated Rauscher MuLV protected against K-234(R) challenge but not against K-234 cell challenge. Antisera prepared from mice immunized with K-234(R) cells were cytotoxic and positive by fluorescent antibody staining for K-234(R) target cells but were not cytotoxic or reactive with K-234 cells. Evidently, the nonproducer K-234 cells lacked transplantation antigens which K-234(R) cells possessed.

- 3809 STRUCTURE AND FUNCTION OF THE POLYPEPTIDES IN SIMIAN VIRUS 40: I. EXISTENCE OF SUBVIRAL DEOXYNUCLEOPROTEIN COMPLEXES. (E.) Huang, E.-S. (Sch. Med., U. North Carolina, Chapel Hill), M. K. Estes and J. S. Pagano. *J Virol* 9(6):923-929, 1972.

SV40 was purified from monkey kidney cells and degraded in dialysis against alkaline buffers at pH 10.5. Degradation products were separated by velocity centrifugation in a 5-20% sucrose gradient. Two components were resolved in sucrose gradients:

soluble protein containing the large viral polypeptides VP1 and VP2; and a deoxyribonucleoprotein complex (DNP-I) containing essentially all the viral DNA and at least three polypeptides (VP4, 5 and 6). DNP-I also contained all or a part of the VP3 polypeptide, some of which was bound to viral DNA. Dissociation of DNP-I by equilibrium centrifugation in cesium chloride yielded a complex (DNP-II) of viral DNA and residual, tightly bound polypeptides, including VP4 and 6 and contaminating VP1; VP5 was thought to be present in DNP-II though it was not resolved. VP3 was absent from DNP-II. Treatment of SV40 with β -mercaptoethanol indicated that there was disulfide bonding between VP1 and VP2. VP3, 4, 5 and 6 may have existed as a linear complex intertwined with viral DNA.

J. Minowada. *Cancer Res* 32:1218-1225, 1972.

Nine human hematopoietic cell lines were inoculated with herpes simplex virus (HSV) type 1. The cell lines included five lines derived from Burkitt lymphoma patients, one line from a myelogenous leukemia patient, one line from an infectious mononucleosis patient, and two lines from normals. Four Burkitt lymphoma cell lines and the two normal cell lines contained Epstein-Barr virus (EBV). The four EBV-positive Burkitt lymphoma cell lines were relatively resistant to HSV infection. Four other cell lines were sensitive to HSV infection. The one EBV-negative Burkitt lymphoma patient cell line was intermediate in HSV-sensitivity. In HSV-sensitive lines, cell viability declined and the incidence of chromosome aberrations increased sharply following HSV inoculation. Heated HSV did not produce impaired cell growth or early chromosome aberrations, but heated HSV decreased cell viability and increased late chromosome aberrations in three non-Burkitt lymphoma patient cell lines. In HSV-resistant lines, cell growth was unimpaired. The incidence of chromosomal aberrations was higher in HSV-resistant lines than in uninfected cell lines, but lower than in HSV-sensitive lines. In general, HSV replication was higher in HSV-sensitive than in HSV-resistant cell lines.

3810 PRESENCE OF VIRAL RNA-INSTRUCTED DNA POLYMERASE IN THE ONCOGENIC SUBVIRAL PARTICLES (VIROSOMES) ISOLATED FROM THE MITOCHONDRIA OF ROUS SARCOMA CELLS. (E.) Kara, J. (Inst. Exp. Biol. Genetics, Czechoslovak Acad. Sci., Prague), M. Dvorak and H. Cerna. *FEBS Letters* 25(1):33-37, 1972.

Rous sarcoma virus (RSV)-specific RNA-instructed DNA polymerase (reverse transcriptase) has been detected in virosomes isolated from the inner membrane and matrix (IM + matrix) fraction of mitochondria prepared from RSV-induced chicken tumors. The virosome fraction, which was isolated on sucrose gradients from the IM + matrix fraction, banded at a density of 1.28g/cm^3 , contained gs antigens, and exhibited cell-transforming ability. Reverse transcriptase activity was detected in the virosome fraction with denatured calf thymus DNA and poly(rA):oligo(dT) templates. The enzyme activity was inhibited by specific rabbit anti-RSV reverse transcriptase.

3813 VIRUS RECOVERY IN CHICKEN CELLS TESTED WITH ROUS SARCOMA CELL DNA. (E.)

Hill, M. (Gustave-Roussy Inst., Villejuif, France) and J. Hillova. *Nature New Biol* 237(71):35-39, 1972.

The ability of a foreign DNA to enter and be integrated into the genome of chicken embryo fibroblasts was studied. After each passage, cultured chick fibroblasts were treated with DEAE-dextran and then grown for 15 min in medium containing DNA purified from nonvirus-producing Rous sarcoma virus (RSV)-transformed rat XC cells. The DNA-treated chick fibroblasts became transformed and began to produce infectious virus particles 12 to 25 days after the first XC-DNA application. Virus recovered from these cultures was able to produce sarcomas when inoculated onto chick embryo chorio-allantoic membrane, and could produce foci of transformed cells typical of those produced by RSV when applied to secondary chicken fibroblast cultures. The rescued virus was antigenically the same as the virus which originally transformed the XC cells.

3811 NEOPLASTIC TRANSFORMATION OF HAMSTER CELLS *IN VITRO* BY BOVINE ADENOVIRUS TYPE-3. (E.) Motoi, M. (Okayama U. Med. Sch., Japan), H. Fukui and K. Ogawa. *Gann* 63(4):415-418, 1972.

Foci of transformed cells appeared in cultures of hamster embryo skin-muscle between 32 and 65 days after infection with adenovirus type 3. Most of the transformed cells were round or spindle-shaped. Bizarre giant cells were also observed. Inoculation of approximately 2×10^5 cells into one-wk-old hamsters by i.p. injection resulted in peritoneal tumors which were histologically similar to the primary virus-induced tumors. Although transformed cells did not release virus, 10-20% were positive for virus-specific T-antigen.

3814 EPSTEIN-BARR VIRUS ASSOCIATED ANTIBODY PATTERNS. (E.) Goldman, M. (Kimron Vet. Inst., Bet Dagon, Israel). *Int J Cancer* 9(2):452-453, 1972.

In an exchange of letters, the matching of controls with lymphocytic lymphoma (LL) patients for serum anti-Epstein-Barr virus (EBV) antibody titers is questioned and defended. EBV-associated serological reactions are more positive in older age groups. It is suggested that this invalidates a conclusion

3812 DIFFERENTIAL EFFECTS OF INFECTION WITH HERPES SIMPLEX VIRUS ON THE CHROMOSOMES OF HUMAN HEMATOPOIETIC CELL LINES. (E.) Huang, C. C. (Roswell Park Mem. Inst., Buffalo, N.Y.) and

that LL patients have significantly higher serum anti-EBV titers than controls, a conclusion based on a sample of LL patients from older age groups. In reply, it is claimed that the conclusion was valid because LL patients studied could be divided into two subgroups, those with well-differentiated and those with poorly-differentiated LL, each subgroup showing different EBV-associated serological reaction patterns.

- 3815 EFFECT OF HERPESVIRUS HOMINIS TYPE 2 ON HUMAN CERVICAL EPITHELIUM: SCANNING ELECTRON MICROSCOPIC OBSERVATIONS. (E.) Wilbanks, G. D. (Rush Med. Coll., Chicago, Ill.) and J. A. Campbell. *Amer J Obstet Gynec* 112(7):924-929, 1972.

Normal human cervical epithelial cells in culture were infected with herpes-virus hominis type 2 from a patient with a primary genital herpes infection. Infected cells were observed using the scanning microscope. By ten hr after infection, cells began to show nuclear changes and cellular coalescence leading to plaque formation. Nuclei showed the "ground glass" appearance of genital herpes infection. Striking changes were seen in the cell membrane. Cells formed clumps with large spaces devoid of cells. Most distinctive were the microvilli of infected cells; these were more numerous than microvilli of normal cells, and showed very variable length and spacing. Small bodies which may have been herpesvirus particles were also seen on cell surfaces.

- 3816 ACQUISITION OF SEQUENCES HOMOLOGOUS TO HOST DEOXYRIBONUCLEIC ACID BY CLOSED CIRCULAR SIMIAN VIRUS 40 DEOXYRIBONUCLEIC ACID. (E.) Lavi, S. (Weizmann Inst. Sci., Rehovot, Israel) and E. Winocour. *J Virol* 9(2):309-316, 1972.

BS-C-1 African green monkey cells were infected at varying multiplicities of infection (MOI) with SV40. Viral closed circular DNA was extracted from infected cells and the ability of viral DNA to hybridize with host cell DNA was studied. It was found that the production of closed circular SV40 DNA homologous to host cell DNA depended on the MOI of SV40 infection. At low MOI (0.032 or 0.16 plaque-forming U (PFU)/cell), the proportion of viral DNA which hybridized with host DNA was low, while at high MOI (4-3,000 PFU/cell), the proportion of viral DNA which hybridized with host cell DNA increased as the MOI increased. The same MOI effect was seen when closed circular SV40 DNA was extracted from purified virions rather than from the infected cell complex. When BS-C-1 cells were infected at high MOI with plaque-purified SV40, none of the SV40 DNA in infected cells was homologous with host cell DNA. However, when undiluted plaque-purified SV40 that had been through several cell passages was used for infection, the production of viral DNA homologous to host cell DNA was restored.

- 3817 EFFECT OF NORMAL SERUM AND ANTITHYMOCYTE SERUM ON FRIEND DISEASE IN MICE. (E.)

Larson, C. L. (Stella Duncan Mem. Inst., U. Montana, Missoula), R. N. Ushijima, R. E. Baker, M. B. Baker and C. A. Gillespie. *J Nat Cancer Inst* 48(5):1403-1407, 1972.

White Swiss mice were injected i.p. or i.v. with Friend disease virus (FDV) four hr after injection of 50 mg silica, a macrophage toxin. Silica markedly enhanced the progress of FDV infection in mice given FDV i.p., but did not affect FDV infection in mice given FDV i.v. In related experiments, FDV-infected mice were injected with anti-thymocyte serum (ATS) prepared in rabbits by injection of RML mouse thymocytes. ATS decreased resistance to infection with FDV injected i.v., to the extent that treated animals infected with 10^{-3} or 10^{-4} virus dilutions died at the same rate as untreated mice infected with 10^{-2} dilutions. Heated or unheated normal rabbit serum (NRS) also increased the susceptibility of mice to FDV infection. Fifty percent of mice given ATS died by 6.2 wk after FDV infection and 50% of mice given NRS died in 8.4-9.2 wk. In untreated mice, 50% mortality was not attained until 13.4 wk after FDV infection. The ability of ATS to enhance FDV infectivity decreased when ATS was absorbed with mouse red blood cells (MRBC) prior to injection; MRBC-absorbed ATS enhancement of FDV infectivity was further decreased by absorption with normal mouse immunoglobulin.

- 3818 POLYNUCLEOTIDE LIGASE IN MOUSE CELLS INFECTED BY POLYOMA VIRUS. (E.) Beard, P. (Imperial Cancer Res. Fund Lab., London, England). *Biochim Biophys Acta* 269(3):385-396, 1972.

Polynucleotide ligase was assayed in mouse embryo cells infected with polyoma virus and in uninfected cells. Two assays were used, one measuring the conversion of (5'- 32 P)phosphoryl end groups in double stranded poly(dA-T) to a phosphate-resistant form, and the other measuring the conversion of single-nick form II polyoma DNA to the covalently circular form. Infection of resting cells by polyoma virus increased ligase activity by 1.8-2.5-fold. Ligase activity began to increase 15-20 hr postinfection and was maximal at 30 hr, time when DNA synthesis was also maximal in infected cells. When infected cells were fractionated by differential centrifugation, 58% of ligase activity was found in cell nuclei and 39% in soluble cytoplasm. Nuclear ligase was in two fractions, one soluble and the other insoluble. Ligase from infected cells behaved similarly to ligase in uninfected cells in the course of a procedure which purified ligases by 160-250-fold. Both ligase from infected and from uninfected cells had molecular wts of 220,000 and pH optima of 7.2-7.8, and required Mg^{2+} and ATP ($K_m = 1.5 \times 10^{-6}M$). Temperature-sensitive mutants of polyoma virus induced the same stimulation of ligase in infected mouse cells as was induced by wild-type virus.

3819 VIRAL DNA SYNTHESIS IN ISOLATED NUCLEI FROM ADENOVIRUS-INFECTED KB CELLS. (E.)

Sussenbach, J. S. (Lab. Physiol. Chem., St. U. Utrecht, Netherlands) and P. C. van der Vliet. *FEBS Letters* 21(1):7-10, 1972.

Viral DNA was isolated from purified nuclei of KB cells 15 hr after infection with adenovirus 5 (Ad5). Isolated nuclei from Ad5-infected KB cells incorporated ^3H -TTP into acid-insoluble material at a linear rate for 30 min, then at a slower rate for at least 2 hr. Nuclei from uninfected cells incorporated much less ^3H -TTP than infected nuclei, with incorporation almost ceasing after 30 min. The new DNA synthesized in isolated nuclei from Ad5-infected cells was characterized by DNA-DNA hybridization, alkaline and neutral CsCl density centrifugation, and alkaline and neutral sucrose gradient centrifugation. New DNA hybridized to Ad5 DNA with the same efficiency as did DNA isolated from virions, but no significant hybridization with KB DNA was seen. Sucrose gradient centrifugation of new DNA showed, in addition to molecules co-sedimenting with 31S (Ad5 DNA) marker, the presence of material which sedimented both faster and slower than the marker. Three fractions from the preparative sucrose gradients were recentrifuged on CsCl gradients. Neutral CsCl centrifugation showed that slowly sedimenting material (III) consisted of 60% viral and 40% cellular DNA. Cellular DNA was less than 5% of total newly synthesized DNA. The "31S" fraction (II) mainly banded at the same position as Ad5 DNA. Fast sedimenting molecules (I) were much heavier (1.722 g/cm^3) than Ad5 DNA. Alkaline CsCl centrifugation indicated that fractions I and II had a viral origin. Neutral sucrose centrifugation confirmed the results seen with CsCl; alkaline sucrose centrifugation showed that new DNA in fraction I banded heterogeneously with a broad peak at 15S and contained no 34S (single Ad5 DNA strands) material. Fraction II was also heterogeneous with molecules ranging from 34S to very small fragments. Under alkaline conditions no DNA molecules larger than genome size were observed.

3820 GENETIC STUDIES WITH TUMORIGENIC ADENOVIRUSES. III. RECOMBINATION IN ADENOVIRUS TYPE 12. (E.)

Takemori, N. (California St. Dept. Public Hlth., Berkeley). *Virology* 47(1):157-167, 1972.

Eighteen nonreverting mutant adenovirus types were used to infect hamster embryo kidney (HEK) cells; the recombination of mutants to form viruses with nonmutant parental properties was observed. The mutants were type *cyt kb*, a class of cytotoxic mutants which failed to propagate in KB-1 cells. In recombination studies, pairs of mutants were used to infect HEK cells and the production of *cyt⁺kb⁺* recombinants (i.e., recombinants which multiplied in B cells) was observed by propagation of viruses in B-1 cells. Virus pairs recombined to form *cyt⁺kb⁺* forms in many cases. These recombinants usually produced a cytopathic effect (CPE) in KB-1 cells similar to the CPE produced by the *cyt⁺* parent virus. After plaque purification, recombinants tested

produced only CPE and plaques like those produced by *cyt⁺* virus. The *cyt⁺kb⁺* recombinants grew readily in KB-1 cells, with titers as high as those produced by parental viruses. The *cyt kb* mutants, however, titered 100-fold less than *cyt⁺kb⁺* recombinants. Production of hexon antigen was enhanced by *cyt⁺kb⁺* recombinants. Recombinants were tumorigenic in newborn hamsters. These results support the hypothesis that *cyt* function is necessary for the production of the characteristic adenovirus *cyt⁺* CPE and for the tumorigenicity of this virus.

3821 PROTEINS SPECIFIED BY HERPES SIMPLEX VIRUS. VI: VIRAL PROTEINS IN THE PLASMA MEMBRANE. (E.)

Heine, J. W. (Dept. Microbiol., U. Chicago, Illinois), P. G. Spear and B. Roizman. *J Virol* 9(1):431-439, 1972.

Previous work has shown that the surface membrane of herpes simplex virus (HSV)-infected cells acquire new immunological specificities and that purified cell membrane preparations contain new glycoproteins genetically determined by the virus. In the present report, purified plasma membranes of HSV-infected human epidermoid carcinoma no. 2 (HEp-2) cells were analyzed by polyacrylamide gel electrophoresis. Comparison of the absorbance tracings of the stained bands of plasma membrane proteins from infected cells with those of uninfected cells showed that the plasma membranes of infected cells contained two sets of protein bands, one characteristically present in uninfected cells and new proteins present only in HSV-infected HEp-2 cells. The synthesis of host plasma membrane proteins, measured by the extent of incorporation of ^{14}C -labeled amino acid precursors, ceased in infected cells; only new membrane proteins were made. After infection, however, no appreciable selective or nonselective loss of host proteins from membranes was observed. Electropherograms of plasma membrane proteins from infected cells indicated the presence of at least 12 virus-specific proteins ranging in molecular wt from 25×10^3 to 126×10^3 daltons. Of these, at least nine were glycosylated as determined by their ability to incorporate ^{14}C glucosamine. Proteins and glycoproteins with similar electrophoretic mobilities, but in somewhat different proportions, were also present in preparations of highly purified virions.

- 3835 EXPRESSION OF FETAL ANTIGENS IN TUMOR CELLS. (E.) Ting, C.-C. (Natl. Cancer Inst., Bethesda, Md.), D. H. Lavrin, G. Shiu and R. B. Herberman. *Proc Nat Acad Sci USA* 69(7):1664-1668, 1972.

A study was conducted to determine the relation of fetal antigens to the specific antigens of mouse tumors induced by papova viruses and also the distribution of fetal antigens in various tumor cells. The activities of sera that reacted specifically with the specific cell-surface antigens of polyoma- or SV40-induced tumors could be inhibited only by absorption of the sera with tumor cells transformed by the specific virus; the activities could not be removed by absorption with cells from various fetal tissues or with cells from other tumors. In contrast, the antisera produced in male C3H/HeN mice by inoculation of X-irradiated, syngenic fetal tissue of one- to two-weeks gestation reacted with various tumor cells. The activities of these sera, when tested against cells from tumors induced by polyoma virus or SV40, could also be removed by absorption with cells from tumors induced by viruses other than polyoma or SV40, including leukemia cells induced by Gross virus, Rauscher virus and by dimethylbenzanthracene, and cells from mammary tumors, plasma-cell tumors, and fetal tissues. These results indicate that fetal antigens may be expressed in tumor cells and that the antigens differ from tumor-specific antigens which are specific for a particular tumor or for tumors induced by a particular virus.

- 3836 THE EFFECT OF CYCLIC ADENOSINE 3',5'-PHOSPHATE ON TUMOR IMMUNITY. (E.) Rigby, P. G. (U. Nebraska, Coll. Med., Omaha). *Cancer Res* 32(3):455-457, 1972.

Ten strain C3H/HeJ mice (male and female, 22-25 g) given 5×10^5 6C3HeD syngeneic live tumor (LT) cells were dead by 30 days, with a mean survival time of 19.5 days. Three of ten mice who were immunized with irradiated tumor cells (XTC) 14 and seven days prior to LT challenge survived longer than 25 days, with all mice dead by 35 days. Four 1.0 mg dose of cyclic 3'5'-adenosine phosphate (AMP) given i.p. after LT resulted in death in all cases within 25 days, as did similar treatment with 2.0 mg yeast RNA. Seven of ten mice given cyclic AMP (six doses) after (XTC) (LT) lived for approximately six months with no tumor evidence. Five of ten mice given RNA after (XTC) (LT) survived six months without tumors. A combination of RNA and cyclic AMP after (XTC) (LT) was effective in improving life span, but no more so than each separately. The results suggest that antigen recognition occurred since immunization was necessary for any prolongation of survival.

- 3837 RESPONSE OF PERIPHERAL BLOOD LYMPHOCYTES FROM NORMAL, HYPOGAMMAGLOBULINEMIC AND CHRONIC LYMPHOCYTIC LEUKEMIC PATIENTS. (E.) Rodey,

G. E. (Milwaukee Blood Ctr., Wisconsin), T. Davis and P. G. Quie. *J Immunol* 108(1):178-182, 1972.

Staphylococcal protein A (SPA) derived from Cowan I strain of *Staphylococcus aureus* was cultured *in vitro* with peripheral blood leucocytes of normal donors and of patients with various diseases. Cells from 17 of 18 normal donors proliferated in the presence of SPA. Maximum tritiated thymidine incorporation occurs with 25 to 50 μ g SPA per culture and when cultures are incubated 7 to 9 days. Removal of glass-adherent cells prior to culture greatly reduced the proliferative response to SPA. The highest response to SPA was seen in cells from three hypogammaglobulinemic patients. None of six patients with chronic lymphocytic leukemia responded to SPA. These findings suggest that the response to SPA is antigen-specific rather than nonselective and that responding lymphocytes are thymus-derived T cells. The failure of chronic lymphocytic leukemic cells to respond to SPA may indicate an abnormality of initial antigen-cell interaction rather than a quantitative deficiency of T-cells.

- 3838 SPECIFIC ANTIGENS OF A CHEMICALLY INDUCED TUMOR; DETECTION BY COMPLEMENT FIXATION. (E.) Albright, N. L. (Natl. Cancer Inst., Bethesda, Md.) and G. H. Myers, Jr. *J Nat Cancer Inst* 49(1):295-297, 1972.

Tumor antigens of a methylcholanthrene (MCA)-induced liposarcoma (MCA-A) previously shown to possess tumor-specific transplantation antigens (TSTA) were detected using the microcomplement fixation test. Adult female strain-2 guinea pigs were given repeated weekly intradermal injections of 10^6 viable MCA-A tumor cells. Sera collected from these animals beginning after the second injection contained a complement-fixing antibody which reacted only with antigens prepared from freshly excised MCA-A tumor or from the tissue culture MCA-A cell line and not with antigens from an MCA-induced osteosarcoma which possessed TSTA or from normal strain-2 guinea pig tissues.

- 3839 ADJUVANT INDUCED RESISTANCE TO TUMOR DEVELOPMENT IN MICE. (E.) Hibbs, J. B., Jr. (Palo Alto Med. Res. Fdn., Calif.), L. H. Lambert, Jr. and J. S. Remington. *Proc Soc Exp Biol Med* 139(3):1053-1056, 1972.

Ten days before *Listeria monocytogenes* challenge, female Swiss-Webster mice were pretreated with 0.1 ml i.p. and s.c. injections of complete Freund's adjuvant (CFA), incomplete Freund's adjuvant (ICFA) or Hank's balanced salt solution (HBSS). CFA stimulated marked resistance to *Listeria*, while ICFA and HBSS controls were not protected. Delayed time to death and/or increased survival was also noted in CFA pretreated mice following i.p. inoculation of 0.2 ml of a 10% suspension of Friend leukemia virus infected spleen cells and i.p. grafts of 1×10^6

Sarcoma 180 cells and 1×10^5 leukemia L1210 cells. In addition, CFA pretreatment caused a statistically significant delay in spontaneous mammary tumor development in C3H/HeJ mice and spontaneous leukemia in AKR mice. These results suggest that host resistance to intracellular infectious agents and neoplasia is related in a fundamental way and that the activated macrophage in resistant animals is a common effector arm for expression of this resistance *in vivo*.

- 3840 SURFACE PROPERTIES OF NON-TUMORIGENIC VARIANTS OF MOUSE MAMMARY CARCINOMA CELLS IN CULTURE. (E.) Hozumi, M. (Nat'l. Cancer Ctr. Res. Inst., Tokyo, Japan), S. Miyake, F. Mizunoe, T. Sugimura, R. F. Irie, K. Koyama, M. Tomita and T. Ukita. *Int J Cancer* 9(2):393-401, 1972.

Studies showing that nonmalignant cells have an increased number of membrane components reacting with phytohemagglutins and tumor-specific antisera are reported. Four mouse cell clones with different transplantabilities in C3H/He mice were used, all derived from mouse mammary tumor cell line FM3A/B. Low-tumorigenic (Cl 1-82) and nontumorigenic clones (Cl M-6) showed much higher agglutinability with plant agglutins than highly tumorigenic clones (Cl 1-614, FM3A/B). The agglutination with wheat germ and *Ricinus communis* was completely inhibited by N-acetyl-D-glucosamine or D-galactose, indicating that surface receptor sites for agglutinins are sugars. The localization of these sites was observed using fluorescent agglutinin: fluorescence on agglutinated nontumorigenic Cl M6 cells was clearly evident and localized on the cell membrane, while fluorescence on nonagglutinated tumorigenic FM3A/B cells was faint and evenly distributed over the cell surface. Surface antigens were detected by the immune adherence test with anti-Cl 1-82 cells, and their content was found to be much higher on Cl 1-82 cells than on Cl 1-614 cells. The increased antigen content was responsible for the induction of strong immunity in Cl 1-82 cells against malignant Cl 1-614 cells.

- 3841 *IN VITRO* DEMONSTRATION OF CELL-MEDIATED IMMUNITY TO HUMAN BRAIN TUMORS. (E.) Levy, N. L. (Duke U. Med. Ctr., Durham, N.C.), M. S. Mahaley, Jr. and E. D. Day. *Cancer Res* 32(3):477-482, 1972.

Several primary human intracranial tumors, both well differentiated and anaplastic, induced tumor-specific, cell-mediated immune responses in an autogenous host. Normal and neoplastic target cells were prepared by tissue culture on a modified Eagle's medium. The cells were dispersed by trypsinization. Peripheral blood lymphocytes were isolated from plasma, eluted with serum-free medium, treated with Tris-ammonium chloride and resuspended in modified Eagle's medium. Microcytotoxicity

studies showed significant inhibition of the neoplastic target cells by autogenous lymphocytes. Patient lymphocytes exerted a tumor-specific effect, while control lymphocytes effected equal reductions in both normal and neoplastic target cells. This nonspecific cytotoxic effect was eliminated by reducing lymphocyte number from 3×10^5 to 1×10^5 /well, using control donors with ABO types identical to those of target cell donors and substituting human AB serum for fetal bovine serum in lymphocyte suspensions. Lymphocytes from a glioblastoma patient were cytotoxic to his own tumor cells and those of another glioblastoma patient, although not reacting to the latter's normal glial cells. Lymphocytes from a melanoma patient reacted against his own tumor cells, glioblastoma cells, normal glial cells and ganglioglioma cells, but not against autogenous or allogenic fibroblasts. Well differentiated and anaplastic tumors were equally able to generate tumor-specific immune response in the host. Of four patients with intracranial tumors of extracerebral origin, three showed significant cell-mediated immunity to their tumors.

- 3842 PRIMARY CANCER OF THE LIVER ASSOCIATED WITH AUSTRALIA ANTIGEN. (Sp.) Velasco, M. (U. Chile, Salvador Hosp., Santiago, Chile), R. Soerensen, A. Daiber, A. Carmona and R. Katz. *Rev Med Chile* 99(9):631-633, 1971.

Australia antigen (Au 1) was detected in serum from three of five patients with primary liver carcinoma. Au 1 was not found in serum from 86 patients with various chronic liver diseases (30 with chronic hepatitis, 29 with alcoholic cirrhosis, 10 with intrahepatic bile duct cancer, 3 with primary biliary cirrhosis, 3 with metastatic cancer of the liver, and 11 with idiopathic jaundice during pregnancy). Patients with primary liver carcinoma did not have a history of hepatitis; all were α -fetoprotein-positive and carried high serum IgG levels. High serum IgM was found in a single case which appeared to be Au-1-negative. The possible role of viral infection in the etiology of liver cancer is discussed.

- 3843 MEASUREMENT OF TRANSFORMATION AND PROLIFERATION OF HUMAN LEUKOCYTES IN CULTURE. (Fr.) Brochier, J. (Antiquaille Hosp., Lyon, France). *Path Biol (Paris)* 19(19-20):833-846, 1971.

The extent to which lymphocytic transformation *in vivo* is affected by various factors: the purification of lymphocytes, the type of serum added to the culture medium, the cellular concentration, and the dose of stimulant used [phytohemagglutinin (PHA), antilymphocytic serum (ALS), tuberculin (PPD), candidin or streptokinase] was studied. Lymphocytes were isolated from venous blood samples by filtration through a nylon column and sedimentation in the presence of dextran. The proliferative response of the lymphocytes to mitogenic or antigenic stimu-

lants was measured by incorporation of tritiated thymidine (^3H -TdR) into the trichloroacetic acid-precipitable sediment. When appropriate concentrations and specific activities were chosen, incorporation during the 24-hr exposure to ^3H -TdR was linear with respect to the number of lymphocytes used in the culture. Certain sera (human AB, A or fetal cal) added to the culture medium appeared to depress or inhibit ^3H -TdR incorporation. A narrow range of concentrations of non-specific stimulants (PHA, ALS) and a 10- to 100-fold wider dose of specific stimulants (PPD, candidin, streptokinase) induced an optimal proliferative response. A kinetic study of the incorporation showed a latent period, followed by an exponential increase, reaching a maximum on day 3 with PHA or ALS and on days 5-7 for antigenic stimulation or a mixed lymphocyte reaction. With standardization of the above parameters, the lymphocyte transformation test is sufficiently reproducible for a tissue culture technique.

lose chromatography was further purified by sucrose gradient centrifugation. The most active fractions of light chain mRNA represented about 0.1% of the RNA originally extracted from the myeloma polysomes and sedimented as a 13S molecule, roughly corresponding to 850 bases. The protein product synthesized from the purified myeloma mRNA formed a specific immunoprecipitate with antibody directed against the MOPC-41 protein. The ability of the myeloma light-chain mRNA to bind selectively to oligo(dT)-cellulose indicates that it contains a region rich in adenylic acid residues. The results suggest that the light-chain mRNA is monocistronic and that it contains about 200 more bases than needed to code for a single light-chain molecule.

3846 DEMONSTRATION OF CARCINOEMBRYONIC ANTIGEN IN NORMAL HUMAN PLASMA. (E.) Chu, T. M. (Roswell Park Memorial Inst., Buffalo, N.Y.), G. Reynoso and H. J. Hansen. *Nature* 238(5360):152-153, 1972.

The presence of carcinoembryonic antigen (CEA), a tumor-specific antigen originally discovered in a tissue extract of human colon adenocarcinoma, was demonstrated (by radioimmunoassay and Sephadex G-200 column chromatography) in a perchloric acid (PCA) extract of pooled plasma from normal healthy individuals. Comparison of the immunoassay inhibition curves from the PCA extract with curves from "true" colonic CEA indicated that the two CEAs were qualitatively the same. CEA concentrations in normal plasma were extremely small compared with amounts found in certain patients with disseminated carcinomas.

3847 LYMPHOCYTE TRANSFORMATION AS AN IMMUNE REACTION IN CHILDREN WITH LEUKEMIA AND THE EFFECT OF ANTILYMPHOCYTE AND ANTIPARABLAST SERA ON LYMPHOCYTE TRANSFORMATION. (Ger.) Zintl, F. (Pediatric Clinic, Jena U., Germany), G. Aurich and W. Plenert. *Folia Haematol* 96(1):14-20, 1971.

Antilymphocyte and antiparablast sera were obtained by immunizing rabbits over a six month period with lymphocytes or "parablasts" in Freund's adjuvant. The effects of these whole sera and their globulin fractions were compared by the radial immunodiffusion method with human sera, the cytotoxicity index, and *in vitro* transformation of phytohemagglutinin of (PHA)-stimulated lymphocytes. While the antilymphocyte serum had approximately the same activity against lymphocytes and parablasts with all three methods, the antiparablast serum had a much stronger activity against parablasts than lymphocytes. PHA-stimulated lymphocyte transformation was markedly lower (40% after 72 hr) in cultures obtained from children with leukemia than those obtained from healthy children (82%). Addition of antilymphocyte and antiparablast sera in concentrations of 5% and 1% by volume significantly decreased lymphocyte transformation (0-12% transformation). The activity

3844 SYNTHESIS, ASSEMBLY, AND SECRETION OF γ GLOBULIN BY MOUSE MYELOMA CELLS. IV. ASSEMBLY OF IgA. (E.) Bargellesi, A. (Albert Einstein Coll. Med., Bronx, N.Y.), P. Periman and M. D. Scharff. *J Immunol* 108(1):126-134, 1972.

The synthesis and assembly of mouse IgA was examined in cultures of Adj-PC 6A myeloma and in MOPC 209B and MOPC 315 tumors. Pulse chain experiments indicated that the pathway of assembly of the IgA monomer in these tumors is $\text{H} + \text{H} \rightarrow \text{H}_2$; $\text{H}_2 + \text{L} + \text{L} \rightarrow \text{H}_2\text{L}_2$; $\text{H}_2\text{L}_2 + \text{H}_2\text{L}_2 \rightarrow (\text{H}_2\text{L}_2)_2$. Acrylamide gel analysis suggested that polymerization of 6A and 315 occurred close to the time of secretion, which began approximately 40 min after synthesis and continued for more than 180 min.

3845 PURIFICATION AND PROPERTIES OF BIOLOGICALLY ACTIVE MESSENGER RNA FOR A MYELOMA LIGHT CHAIN. (E.) Swan, D. (Lab. Molecular Genetics, Natl. Inst. Hlth., Bethesda, Md.), H. Aviv and P. Leder. *Proc Nat Acad Sci USA* 69(7):1967-1971, 1972.

Biologically active mRNA, which directs synthesis of mouse myeloma (MOPC-41) kappa chain, was purified from a microsomal fraction by oligothymidylate [oligo(dT)]-cellulose chromatography and sucrose gradient centrifugation. The mRNA was assayed in a cell-free Krebs II ascites tumor system and the radiolabeled protein products were compared with an authentic light-chain standard and with proteins synthesized endogenously on MOPC-41 membrane-bound polysomes. Tryptic peptide analysis by Dowex-1 column and cation exchange chromatography indicated that the *in vitro* protein products of purified mRNA contained all the MOPC-41 amino acid sequences. The major MOPC-41 mRNA-directed protein product comigrated with the authentic light-chain standard on SDS-polyacrylamide gels. The mRNA purified by oligo(dT)-cello-

of antilymphocyte sera was stronger since a decrease in transformation was still obtained with 0.5% by volume; this was not the case with antiparablast serum.

- 3848 RNA TUMOR VIRUS *gs* ANTIGEN AND TUMOR INDUCTION BY VARIOUS DOSES OF 3-METHYLCHOLANTHRENE IN VARIOUS STRAINS OF MICE TREATED AS WEANLINGS. (E.) Whitmire, C. E. (Microbiol. Assoc., Inc., Bethesda, Md.) and R. A. Salerno. *Cancer Res* 32(6):1129-1132, 1972.

The effect of various doses of 3-methylcholanthrene (MC) on s.c. tumor induction and the occurrence of the murine C-type RNA group-specific (*gs*) viral antigen in tumor tissue (detected by complement fixation) were studied in weanling mice of eight genotypically different strains. Tumor incidence was found to be related to the dose of MC. However, the incidence of *gs* antigen in the induced tumors was independent of the dose of MC and reflected the natural *gs* antigen expression of the mouse strain. Histopathological examination showed no relation of tumor type to carcinogen dosage or mouse strain. The majority of the tumors examined were sarcomas. These studies confirmed earlier findings, which suggested that the *gs* antigen expression induced in tumors was dependent on host-regulatory controls and that such controls of virogene (*gs* antigen) and oncogene (tumor induction) expressions of the C-type RNA viral genome were independently affected by a carcinogen.

- 3849 ISOLATION AND CHARACTERIZATION OF HUMAN FOETAL α_1 F GLOBULIN (α_1 F) FROM FOETAL AND HEPATOMA SERA. (E.) Adinolfi, A. (Guy's Hosp. Med. Sch., London, England), M. Adinolfi and S. Cohen. *Biochim Biophys Acta* 251(2):197-207, 1971.

The fetal protein α_1 F was isolated by the antigen-antibody method from the sera of ten fetuses and from the blood of a hepatocellular carcinoma patient. The protein was labeled with radioactive iodine and subjected to gel electrophoresis. The purified protein from either fetal or hepatoma sera eluted as a single peak from Sephadex G-200, indicating a single peptide chain. The labeled material was then collected, precipitated, and re-Sephadexed. The molecular weights of the labeled α_1 F isolated from fetal and hepatoma sera were 61,000 and 63,000 resp. Treatment with neuraminidase reduced the electrophoretic mobility of the α_1 F protein, indicating the presence of sialic acid in relation to the peptide chain.

- 3850 NEOPLASTIC ANTIGEN STUDIES. (It.) Barbieri, A. De (S. Belfanti Inst. Serum Ther. Milan, Italy) and G. C. Tassi. *Boll Ist Sieroter Milan* 50(4):243-249, 1971.

Human tumors (carcinomas of the breast, stomach, lungs, and sigmoid colon and malignant lymphogranuloma and melanoma) were homogenized, subjected to ultrasound, and centrifuged. The supernatant, which contained cell membranes, mitochondria, microsomes, and soluble cytoplasmic protein, was conjugated with acetylated rabbit α -globulin in the presence of 1-cyclohexyl-3(2-morpholinyl-4-ethyl)carbodiimide methoxyl-*p*-toluene sulfonate and dialyzed. After fractionation of Sephadex G-166, the tumor protein-acetylated immunoglobulin conjugate was concentrated and freeze-dried. These antigen conjugates were injected s.c. once a day for three days into patients with a variety of malignant neoplasms; a fourth injection was given 15 days after the first and a fifth injection followed one month later; thereafter, injections were given once a month. With each injection 40 mg of the conjugate was administered. Hemagglutination tests, run 1-2 months after immunotherapy was begun, showed that these patients developed antibodies to both the whole conjugate and the haptene. Autologous vaccine tended to produce higher antibody titers than homologous vaccine.

- 3851 COMPARISON OF AN IMMUNORESISTANT AND AN IMMUNOSUSCEPTIBLE ASCITES SUBLINE FROM MURINE TUMOR TA3. I. TRANSPLANTABILITY, MORPHOLOGY, AND SOME PHYSICOCHEMICAL CHARACTERISTICS. (E.) Friberg, S., Jr. (Karolinska Inst. Med. Sch., Stockholm, Sweden). *J Nat Cancer Inst* 48(5):1463-1476, 1972.

Cells of the TA3 spontaneous carcinoma of an A/HeHa mouse were injected i.p. into normal mice of nine strains; the cells were TA3 sublines TA3-Ha and TA3-St. TA3-St cells grew in five of 96 allogeneic mice and showed a preference for mice of the A/Sn strain. TA3-Ha transgressed all histoincompatibility barriers tested, even at small cell inocula (10^3 cells), and grew in 80 of 96 mice. TA3-Ha cells also grew in some rats and hamsters. Under the electron microscope, TA3-Ha cells showed a smoother surface structure than TA3-St cells. The TA3-St cells had a modal chromosome number of 66 and showed two or three biarmed chromosomes; the modal chromosome number for TA3-Ha cells was 41 and no marker chromosomes were seen. The TA3-Ha line grew slightly faster than the TA3-St line in A/Sn mice. The electrophoretic mobility (EPM) of TA3-Ha cells was higher than that of TA3-St cells (mean EPM of TA3-Ha = $1.56 \pm 0.010 \mu\text{sec}^{-1} \text{ volt}^{-1} \text{ cm}$, versus $1.27 \pm 0.012 \mu\text{sec}^{-1} \text{ volt}^{-1} \text{ cm}$ for TA3-St). This indicated that TA3-Ha cells had a 20% higher net-negative surface charge than TA3-St cells. TA3-Ha cells were not agglutinated by the plant lectin Con A, while TA3-St cells were readily agglutinated.

- 3852 THE ANTIBODY RESPONSE OF MICE TO MURINE LEUKEMIA VIRUS IN SPONTANEOUS INFECTION: ABSENCE OF CLASSICAL IMMUNOLOGIC TOLERANCE. (E.) Oldstone, M. B. A. (Scripps Clin. Res. Fdn., La Jolla,

Calif.), T. Aoki and F. J. Dixon. *Proc Nat Acad Sci* 69(1):134-138, 1972.

Gross murine leukemia virus (GMuLV)-infected male and female AKR mice were studied at three, six and nine months, using direct and indirect immunofluorescence to detect the presence of viral antigen, host immunoglobulin (Ig), third complement component (C3), albumin and fibrinogen. Assay of kidney tissue revealed an increasing number of mice positive for host IgG and C3 reaching a maximum of 95% positive mice at nine months. IgG and C3 were restricted to glomeruli. GMuLV antigens were detected in glomeruli, convoluted tubules, connective tissue and arterial endothelium, in addition to most tissues assayed. Viral antigens were present in highest amounts in thymus. Antibodies to GMuLV antigens were detected in AKR mice by indirect immunofluorescence, complement fixation and hybrid antibody assay. Antibody to GMuLV surface antigen was not detected in plasma of infected AKR mice. The detection of host Ig, C3 and GMuLV antigen in glomeruli suggested that circulating GMuLV antigen-anti-GMuLV antibody complexes probably occurred. AKR mice most likely produced at least two distinct antibodies to GMuLV: 1) complement-fixing antibodies immunologically related to internal viral components; and 2) antibody directed toward GMuLV surface antigens. *In utero* infection with GMuLV probably did not induce complete tolerance to Gross antigens in AKR mice.

3854 SPECIFIC INHIBITION OF RECEPTORS FOR CYTOPHILIC ANTIBODY ON MACROPHAGES BY ISOANTIBODY. (E.) Mitchell, M. S. (Yale U. Sch. Med., New Haven, Conn.) and M. B. Mokyr. *Cancer Res* 32(4):832-838, 1972.

Hyperimmune antibody-rich ascitic fluid against L1210 leukemia (Ab) was injected i.p. into C57BL/6J mice (0.4 ml) one day before the mice were challenged with L1210 cells i.p. Cytophilic antibody activity on peritoneal monocytes was assayed *in vivo* and *in vitro* by observing formation of macrophages and attachment of L1210 cells by macrophages. Ab-treated mice showed unvacuolated, quiescent-looking monocytes when assayed ten days after L1210 challenge; Ab-treated mice formed one-sixth to one-tenth the number of macrophages formed by control mice injected with normal ascites fluid or NaCl. Active acid phosphatase was lacking in monocytes from Ab-treated mice. Macrophages in these mice seemed not to attack or ingest L1210 cells. Addition of proven cytotoxic antibody to L1210 failed to restore the capacity of monocytes in Ab-treated mice to attack tumor cells. Treatment with Ab did not prevent the attachment of sheep erythrocytes (SRBC) by peritoneal monocytes of Ab-treated mice following addition of cytophilic antibody to SRBC. The suppressive activity of Ab was confined to its IgG fraction. These results indicated that receptor sites for cytophilic antibody on the surface of peritoneal monocytes are inhibited by Ab.

3853 RECEPTORS FOR IMMUNOGLOBULIN ON B LYMPHOCYTES AND CELLS OF A CULTURED PLASMA CELL TUMOR. (E.) Cline, M. J. (U. California Sch. Med., San Francisco), J. Sprent, N. L. Warner and A. W. Harris. *J Immunol* 108(4):1126-1128, 1972.

Thymocytes and thoracic duct lymphocytes, consisting of 65-99% θ C3H antigen-positive (T) cells, were taken from CBA/H/WEHI mice. Nonthymus or bone-marrow derived (B) lymphocytes were taken from thymectomized CBA mice. Cells from six mouse plasmacytomas, two thymomas and a peripheral lymphoma were also obtained. T cells, B cells, and tumor cells were incubated with sheep erythrocytes (SRBC) coated with IgM- and IgG-rich fractions of a mouse antiserum to SRBC. An F(ab')₂ fraction of the IgG antibody was also prepared and reacted with test lymphocytes and tumor cells. The proportion of cells bearing adherent SRBC (rosettes) was observed. Cells from one plasmacytoma (HPC-6, from an NZB mouse) and B lymphocytes formed rosettes with IgG-coated SRBC, while T cells did not. SRBC sensitized with IgM or F(ab')₂ were nonreactive. Binding of IgG to cells required an intact Fc piece, but was independent of complement. Cells from two other plasmacytomas reacted weakly with IgG-SRBC; the remaining three plasmacytoma cells and the thymoma and lymphoma cells did not show the type of binding characteristic of B lymphocytes and HPC-6 cells. The results are consistent with the hypothesis that the B lymphocyte is a progenitor of the plasma cell.

3855 IMMUNOLOGICAL COMPETENCE OF SPLEEN CELLS FROM RATS BEARING SYNGENEIC OR AUTOCHTHONOUS TUMOURS. (E.) Medzihradsky, J. (Slovak Acad. Sci., Bratislava, Czechoslovakia), E. Konikova and L. Novotna. *Neoplasma* 19(2):105-110, 1972.

F₁ hybrid rats were given footpad grafts of spleen cells from parent rats bearing grafted 3-methylcholanthrene-induced fibrosarcomas or primary fibrosarcomas induced by 3-methylcholanthrene injections. The ability of spleen cells from tumor-free and tumor-bearing donors to induce a graft-versus-host immune response (GVHR) in spleen cell recipients was measured by observing the enlargement of recipients' popliteal lymph nodes after spleen grafting. Significant reduction of GVHR-inducing activity of spleen cells from tumor-bearing rats was seen on the fifth and seventh days after spleen cell grafting. GVHR impairment had disappeared by day ten. This suggested that depressed donor cell proliferation may have caused the impairment of GVHR. Among recipients of spleen cells from primary methylcholanthrene-induced tumors, GVHR-reducing capacity of spleen cells was seen only when donors' tumors were small and without necrosis inside the tissue.

3856 CYTOPLASMIC IMMUNOFLUORESCENCE OF BLOOD CELLS FROM MYELOMA, HODGKIN'S DISEASE AND LYMPHOSARCOMA CASES. (E.) Bankole, R. O. (Metropolitan Med. Ctr., Minneapolis, Minn.), H. A.

Bates, W. R. Swaim and D. S. Amatzio. *Brit J Cancer* 26(1):10-14, 1972.

Peripheral blood was drawn from ten multiple myeloma, ten Hodgkin's disease and 11 lymphosarcoma patients; leukocytes were separated out by centrifugation and reacted in immunofluorescence tests with antisera prepared against Rauscher virus murine leukemia (AMR) and human stem leukemia plasma (AHS). Leukocytes from nine multiple myeloma, seven Hodgkin's disease and nine lymphosarcoma patients showed significant cytoplasmic fluorescence reactions with both AMR and AHS or with AHS alone. No positive reactions of leukocytes to AMR alone were seen. Absorption tests suggested that the observed cytoplasmic immunofluorescence reactions involved cellular isoantigens. Serial studies on seven cases including cases of each of the three conditions mentioned, indicated that a relationship existed between clinically active disease and the presence of fluorescing cells.

3857 EFFECT OF TRANSIENT IMMUNOSUPPRESSION ON HOST RESPONSE TO NEONATALLY INTRODUCED ONCOGENIC VIRUS. (E.) Blair, P. B. (Cancer Res. Genet. Lab., U. California, Berkeley). *Cancer Res* 32(2):356-359, 1972.

BALB/c female mice, which normally lack mammary tumor virus (MTV) were given immunosuppressive injections of either antithymocyte serum (ATS) or normal rabbit serum (NRS); C3H female mice, which normally carry MTV, were given globulin preparations of ATS (ATG) or globulin preparations of NRS (NRG). Some mice given the immunosuppressive treatments were inoculated with isogenic mammary tumor cells to test cell-mediated immune reactivity of serum. In C3H mice not given tumor inocula, none of those given NRG developed circulating anti-MTV antibodies in serum; 62% of C3H mice given ATG but no tumor cells developed serum antibodies. Both NRG- and ATG-treated C3H mice inoculated with mammary tumor cells showed serum anti-MTV antibody. More ATG-treated mice than NRG-treated mice developed antibody (83 vs 38%). In BALB/c mice, anti-MTV antibodies appeared earlier in ATS-treated than in NRS-treated animals.

3858 TWO KINDS OF ANTIGEN SUPPRESSION IN TUMOR CELLS REVEALED BY CELL FUSION. (E.) Klein, G. (Dept. Tumor Biol., Karolinska Inst., Stockholm, Sweden), S. Friberg, Jr. and H. Harris. *J Exp Med* 135(4):839-849, 1972.

The TA3/Ha subline of the TA3 mouse ascites mammary tumor was fused with ACA mouse embryo fibroblasts; antigenic typing was performed on nine hybrid clones and compared with the antigenic patterns of TA3 sublines TA3/Ha and TA3/St. The TA3/St line was high in H-2^a antigen, grew in 100% of syngeneic strain A mice on transplantation, and was regularly rejected by allogeneic transplant recipients.

The immuno-resistant TA3/Ha subline had drastically reduced antigen concentrations and grew in allogeneic, H-2-incompatible mice. ACA fibroblasts were normal diploid cells and contained H-2^f antigen. All the nine clones established from fusion of the TA3/Ha and ACA cells showed H-2^a antigen. Three hybrid clones exceeded TA3/Ha in H-2^a antigen expression but were not as expressive of the H-2^a as were TA3/St cells. Other hybrids exceeded TA3/St cells in H-2^a expression. Hybrid cells showed increased expression of the K-end antigens of the H-2^a complex introduced into hybrids by the TA3/Ha parent. ACA cells carried no H-2^d antigen and TA3/Ha cells contained little H-2^d antigen. However, all hybrid clones contained relatively high amounts of H-2^d. Neither TA3/St nor the parent TA3/Ha cells carried H-2^f antigen. However, all but one hybrid cell line carried this antigen, which was apparently contributed by the ACA parent. These results suggest that reduced antigen expression in TA3/Ha cells is due to some deficiency that can be compensated for by the ACA fibroblast.

3859 EFFECT OF TUMOR CELL INOCULATION ON CIRCULATING LYMPHOCYTES. (E.) Fisher, B. (U. Pittsburgh Sch. Med., Pa.), E. A. Saffer and E. R. Fisher. *Proc Soc Exp Biol Med* 139(3):787-792, 1972.

C3H mammary tumor cells, C3H kidney cells and methylcholanthrene (MC)-induced tumor cells were injected s.c. or i.v. into C3HeB/FeJ female mice that had (a) received no prior injection of normal or tumor tissue, (b) were harboring a 14-day C3H or MC tumor, (c) had a previously growing C3H tumor removed two wk prior the challenge injection or (d) had been injected two wk before with normal kidney cells. S.c. inoculation with C3H tumor cells profoundly depressed lymphocyte counts (18-22% of normal) in mice without prior treatment, in mice with a growing MC tumor and in mice previously injected with kidney cells. The depression was maximal two days postinjection. Similar s.c. injection of C3H tumor cells in mice with growing C3H tumors or in mice from which such tumors had been excised did not effect a significant decrease in lymphocyte count. Inoculation of C3H kidney cells depressed lymphocyte counts in normal mice but not in mice previously exposed to tumor or kidney cells. I.v. injection of C3H tumor cells produced results similar to those observed following s.c. injection. The effects of s.c. and i.v. injections of MC tumors paralleled those of C3H tumor injections. Administration of antilymphocyte serum prior to and during the presence of immunizing C3H tumors prevented lymphocyte counts from decreasing after subsequent tumor challenge.

3860 SMOOTH MUSCLE ANTIBODY IN MALIGNANT DISEASE. (E.) Whitehouse, J. M. A. (Chester Beatty Res. Inst., Sutton, England) and E. J. Holborow. *Brit Med J* 4(5786):511-513, 1971.

Smooth muscle (S.M.) antibody in sera from 80 patients

with malignant tumors and from 46 normal subjects was surveyed by the indirect "sandwich" method of fluorescent staining. - Sections containing serum (1/10 dilution) were examined for staining at five sites: smooth muscle fibers between gastric glands, muscularis mucosae, artery walls, liver cells and renal glomeruli. Positivity was assessed by a point system. S.M. antibody in sera from patients with malignant disease seemed identical to that in sera of hepatitis patients. Antinuclear factor incidence was 24% in cancer patients and absent in neuroblastoma and control subjects. A new IgG antibody was found in seven sera (one control, one malignant melanoma, five neuroblastoma). Staining patterns of both antibodies were closely related in liver, glomeruli and arterial wall sites, but the new antibody did not stain the gastric muscularis mucosae of smooth muscle fibers between gastric glands. While S.M. antigen titrated out at maximum dilution 1/40, the new antibody still stained strongly at 1/320 dilution. This antibody provides further evidence that autoantibodies against normal tissue components may be produced in malignant disease.

3861 RAPID *IN VITRO* DETECTION OF CELLULAR IMMUNITY IN MAN AGAINST FRESHLY EXPLANTED ALLOGENEIC CELLS. (E.) Wunderlich, J. R. (Nat'l. Cancer Inst., Bethesda, Md.), G. N. Rogentine, Jr. and R. A. Yankee. *Transplantation* 13(1):31-37, 1972.

Lymphocytes from blood of three multiply transfused patients with aplastic anemia, and normal blood lymphocytes, were reacted with selected allogeneic or autologous cells in ⁵¹Cr-release cytotoxicity tests. Normal lymphocytes were not cytotoxic to autologous normal lymphocytes or to allogeneic target cells. Lymphocytes from patient donors presensitized by transfusions showed cell-mediated immunity against allogeneic cells. These lymphocytes strongly lysed cells from HL-A-nonidentical donors as well as cells from HL-A-identical siblings. However, presensitized lymphocytes did not damage autologous target cells. Cytotoxicity of presensitized lymphocytes appeared to result directly from direct contact of immune lymphocytes and target cells; toxins were not found to be associated with the cytotoxicity reaction.

3862 TUMOR-ASSOCIATED IMMUNOGLOBULINS: ENHANCEMENT OF SYNGENEIC TUMORS BY IgG2-CONTAINING TUMOR ELUATES. (E.) Ran, M. (Dept. Microbiol. Tel Aviv U., Israel) and I. P. Witz. *Int J Cancer* (1):242-247, 1972.

Cells of transplantable methylcholanthrene- or benzo(a)pyrene-induced sarcomas were harvested from C3H mice and tumor cell eluates containing IgG2 were prepared by the pH 2.4 glycine method. C3H mice were injected i.m. with cells of the carcinogen-induced tumors after the cells had been preincubated with IgG2-containing eluates derived from tumors of the same line as those used

for challenge injection (autologous eluates); some mice were injected with tumor cells preincubated with IgG2-containing eluates derived from other tumors syngeneic with those used for challenge, or various other primary tumors. Preincubation of tumor cells with autologous eluates enhanced tumor production in injected mice more than preincubation of tumor cells with isologous eluates; 63 tumors were produced in 93 inoculated mice given tumor cells preincubated with autologous eluates while 69 tumors developed in 126 mice given tumor cells preincubated with isologous eluates. Of 149 mice injected with tumor cells not incubated with any eluate, 55 developed tumors. Inoculation of tumor cells mixed with autologous eluates caused a slightly earlier appearance of tumors than inoculation of tumor cells mixed with isologous eluates, or inoculation of tumor cells alone. On the whole, the differences were not statistically significant.

3863 SUPPRESSED ACTIVITY OF THYMUS-DERIVED CELL IN TUMOR-BEARING HOST. (E.) Takatsu, K. (Osaka U. Med. Sch., Japan), T. Hamaoka, U. Yamashita and M. Kitagawa. *Gann* 63(2):273-275, 1972.

Strain dd0 albino mice were inoculated s.c. with Ehrlich ascites tumor cells; later, tumor-bearing and uninoculated, tumor-free mice were immunized s.c. and i.p. with bacterial α -amylase and dinitrophenyl-Taka-amylase. Lymph node and spleen cells were prepared from α -amylase-immunized normal or tumor-bearing mice (carrier-primed cell donors) and from dinitrophenyl-Taka-amylase-immunized normal or tumor-bearing mice (hapten-primed donors); lymph node and spleen cells from the respective donors were combined in the presence of dinitrophenyl-bacterial α -amylase and then transferred i.v. into 600 R X-irradiated recipient mice. Anti-hapten plaque-forming cells in recipients' spleens were assayed. Plaque-forming cells decreased significantly in recipients of carrier-primed or hapten-primed cells from tumor-bearing donors as compared to recipients of primed cells from tumor-free mice. Evidently, helper activity was suppressed in tumor bearing carrier-primed donors. Anti-hapten antibody titers were also reduced in recipients of carrier-primed cells from tumor-bearing donors as compared to recipients of carrier-primed cells from tumor-free donors. It was concluded that the immunological activity of thymus-derived cells is impaired in tumor-bearing donors.

3864 OCCURRENCE OF HERPES- AND ADENOVIRUS ANTIBODIES IN PATIENTS WITH CARCINOMA OF THE CERVIX UTERI: MEASUREMENT OF ANTIBODIES TO HERPESVIRUS HUMANUS (TYPES 1 AND 2), CYTOMEGALOVIRUS, EB-VIRUS, AND ADENOVIRUS. (E.) Vestergaard, B. F. (Inst. Med. Microbiol., Copenhagen, Denmark), A. Hornsleth and S. N. Pedersen. *Cancer* 30(1):68-74, 1972.

One hundred thirty-five sera from patients with newly

diagnosed, untreated cervical cancer and 115 sera from healthy women matched for age and socioeconomic background were examined for antibodies to *Herpesvirus hominis* (types 1 and 2), cytomegalovirus, EB-virus and adenovirus. No difference was observed in the incidence of *Herpesvirus hominis* type 1. Eighty-five per cent of the patients with cervical cancer had antibodies to *Herpesvirus hominis* type 2 compared to 47% in the control group. The incidences of antibodies to cytomegalovirus and EB-virus were significantly greater in the sera from patients with cervical cancer than in control sera. The incidence of antibodies to adenovirus was the same for both groups. The incidences of antibodies were not correlated to the clinical stages of the disease. In the control group, antibodies to *Herpesvirus hominis* type 2 and EB-virus were found with higher incidence among women with low socioeconomic background than in women from higher social classes. Such a correlation was not seen in patients with cervical cancer.

3865 ULTRASTRUCTURAL SURVEY OF PRIMARY LIVER CELL CARCINOMAS FROM UGANDA. (E.)

O'Connor, G. T. (Natl. Cancer Inst., Bethesda, Md.), T. S. Tralka, E. Henson and C. L. Vogel. *J Nat Cancer Inst* 48(3):587-603, 1972.

Seventeen surgical biopsy specimens of primary liver cell carcinoma from Ugandans were examined under the electron microscope. The fine structural features of these specimens were similar to those reported in other studies, suggesting that there are no essential difference between the fine structure of liver cancers in Africans and Caucasians. The most important general characteristic of the liver cell cancers was the loss of orderly arrangement and organization of cytoplasmic components as compared with normal liver cells. Mitochondria showed considerable pleomorphism. All specimens except one were of intermediate differentiation; there were no highly anaplastic tumors. No morphologic correlation with serum α -feto-protein or with Australia antigen was found. A search for virus or virus-like particles in the liver cancer specimens produced negative results.

3866 THE IMMUNOCAPACITY OF THE AKR MOUSE. (E.) Hargis, B. J. (Children's Cancer Res. Fdn., Inc., Boston, Mass.) and S. Malkiel. *Cancer Res* 32(2):291-297, 1972.

Mice of the high leukemic AKR strain were examined for anaphylaxis and for the capacity of their spleen cells to cause a graft-vs-host reaction (GVH) when implanted in CFW mice. AKR mice develop leukemia in 85% of cases between six and eight months of age. The splenic index and the thymic index of CFW mice given spleen transplants from AKR mice aged one to 11 months indicated that AKR spleen cells elicited a GVH reaction. The leukocyte counts in spleen-grafted CFW mice showed considerable variation; the leukopenia expected to attend GVH reactions was not

seen in all cases. A 35% mortality from anaphylaxis was seen in two-month-old AKR mice; the anaphylaxis mortality rose to 87% in mice seven months old or older.

3867 IMMUNOLOGICAL RELATIONSHIPS OF REVERSE TRANSCRIPTASES FROM RIBONUCLEIC ACID TUMOR VIRUSES. (E.) Parks, W. P. (Natl. Cancer Inst., Bethesda, Md.), E. M. Scolnick, J. Ross, G. J. Todaro and S. A. Aaronson. *J Virol* 9(1):110-115, 1972.

RNA-dependent DNA polymerase from the C-type Rauscher murine leukemia virus (R-MuLV) and Schmidt-Ruppin Rous sarcoma virus (SR-RSV), and from the Mason Pfizer monkey virus (MS-MV) was partially purified by gel filtration and phosphocellulose chromatography. DNA polymerase was injected into New Zealand rabbits to produce anti-DNA polymerase antiserum, which was used to inhibit viral DNA polymerase. Anti-R-MuLV antisera reduced R-MuLV DNA polymerase by more than 50% but did not affect SR-RSV polymerase. Conversely, antiserum to the SR-RSV (avian) DNA polymerase inhibited SR-RSV polymerase by 90% but did not affect the R-MuLV (murine) polymerase. Purified IgG isolated from anti-DNA polymerase antisera had a higher specific activity for enzyme inhibition than whole serum. The effect of avian and murine C-type virus polymerase antisera on the DNA polymerase of other RNA-containing viruses was studied. IgG from anti-SR-RSV polymerase antiserum inhibited this enzyme in other avian viruses but not in viper C-type or in any mammalian viruses. Antiserum which inhibited R-MuLV polymerase failed to inhibit DNA polymerase in rat and feline leukemia viruses, visna virus, MP-MV or simian "foamy" virus type 3. IgG from anti-R-MuLV polymerase antisera inhibited R-MuLV polymerase with each of four DNA polymerase templates tested.

3868 TUMOR-SPECIFIC, CELL-MEDIATED IMMUNE RESISTANCE TO AUTOCHTHONOUS TUMORS. (E.) Kikuchi, K. (New York U. Med. Ctr., N.Y.), Y. Kikuchi, M. E. Phillips and C. M. Southam. *Cancer Res* 32(3):516-521, 1972.

Tumor-specific, cell-mediated immune reactions in the autochthonous tumor-host system of Lewis rats were studied *in vitro* using time-lapse cinemicrography and the ^{51}Cr release cytotoxic test. A Millipore filter technique was used to investigate immunocyte-mediated target cell destruction. Methylcholanthrene-induced rat tumors were transplanted into syngeneic rats, with strangulation of the remaining tumor in the original rat. The original rats were then tested for transplantation resistance to their own tumor by transplanting the tumor from the syngeneic host to which it had been passed. Peritoneal, spleen and lymph node cells were then harvested. Cell lines from 6 tumors were highly antigenic, 13 moderately so and 23 of low antigenicity. Fifteen autochthonous hosts were used as sources of immunocytes and serum for the *in vitro* cytotoxicity tests. There was no significant increase in

net release of ^{51}Cr by labeled tumor cells admixed with nonimmune syngeneic peritoneal cells, yet a high release of label occurred with highly and moderately antigenic cells admixed with autochthonous peritoneal cells. Autologous spleen and lymph node cells seldom released more chromate than their corresponding syngeneic, nonimmune cells. Cross reaction studies by the ^{51}Cr release technique suggested specificity of the cytotoxic reaction against the autochthonous tumor. The ^{51}Cr studies also showed a direct relationship between *in vivo* transplantation resistance and *in vitro* cytotoxicity of autochthonous peritoneal cells. Time-lapse, phase-contrast cinemicrography of a highly antigenic tumor showed tumor cell population decreasing during incubation with autochthonous peritoneal cells, the decrease first evident at 12 hrs and very marked at 24 hrs. Tumor cells in two of five tumor lines were destroyed by autogenous peritoneal cells acting through a Millipore membrane barrier, suggesting production of a diffusible cytotoxic substance by immunocytes of the primary host.

an electron microscope. The three H-2 antigens were distributed similarly on leukemia cell surfaces; the average contents of the antigens on cell surfaces were 24% for Rauscher virus (H-2^d); 23% for Friend virus (H-2^d); 16% for Graffi virus (H-2^b); 20% for Mazurenko virus (H-2^b); 24% for SZ virus (H-2^b); and 13% for Gross virus (H-2^k). The proportion of mature virus particles with H-2 antigens on their surfaces ranged from 7-15%. No virus had more than five to seven ferritin molecules used to mark H-2 antigens on its surface and no virus particles were fully covered by H-2 antigens. The same was true of budding viruses in leukemia cells; even on membrane sites which had H-2 antigens, buds were devoid of antigen. Possible reasons for the absence of H-2 antigens on mature and budding viruses are discussed.

3871 EXPRESSION OF VARIOUS TUMOR-SPECIFIC ANTIGENS IN POLYOMA VIRUS-INDUCED TUMORS. (E.)

Ting, C.-C. (Natl. Cancer Inst. Bethesda, Md.), D. H. Lavrin, K. K. Takemoto, R. C. Ting and R. B. Herberman. *Cancer Res* 32(1):1-6, 1972.

Antigen expression in polyoma virus-induced tumors was studied. Cells of two lines were used: polyoma 4198, which originated in culture from polyoma virus-transformed mouse cells; and 4198V, a variant of 4198. 4198V arose during passage *in vitro*; it was similar to 4198 in *in vitro* growth rate and in morphology but showed a marked decrease in *in vivo* growth rate in nonirradiated mice compared to 4198. In *in vivo* immunorejection tests, immunization of mice with 4198 or 4198V cells did not protect against challenge with 4198 cells. However, mice immunized with 4198 or 4198V cells were protected against challenge with 4198V cells (100- and 500 fold protection, resp., in mice immunized with 4198 and 4198V cells). 4198 cells were thus more immunosensitive than 4198V cells and presumably possessed more polyoma tumor-specific transplantation antigen. 4198V cells had 8.8 times more tumor-specific cell surface antigen than 4198 cells as detected by the isotopic antiglobulin method. In immunofluorescence tests and complement fixation tests, 4198 cells showed no T-antigen while all 4198V cells tested were strongly positive for T-antigen.

3872 ASSAY FOR CELL TUMORIGENICITY IN SUBHUMAN PRIMATES TREATED WITH ANTILYMPHOCYTE

GLOBULIN. (E.) Petricciani, J. C. (Natl. Inst. Hlth., Bethesda, Md.), R. L. Kirschstein, R. E. Wallace and D. P. Martin. *J Nat Cancer Inst* 48(3):705-713, 1972.

Newborn, infant and juvenile rhesus monkeys and African green monkeys were injected s.c. with rabbit antilymphocyte globulin (ALG) (13-50 mg/kg) ten days before inoculation i.m. of human epidermoid carcinoma cells (KB cells) in doses of 10^4 - 10^7 cells. The 10^7 dose produced large, progressively growing tumors i.m. in all of 12 rhesus monkeys treated,

3869 SYNERGISTIC OR ANTAGONISTIC EFFECT OF DIFFERENT ANTIBODY CONCENTRATIONS ON *IN VITRO* LYMPHOCYTE CYTOTOXICITY IN THE MOLONEY SARCOMA VIRUS SYSTEM. (E.) Skurzak, H. M. (Dept. Tumor Biol., Karolinska Inst., Stockholm, Sweden), E. Klein, T. O. Yoshida and E. W. Lamon. *J Exp Med* 135(4):997-1002, 1972.

Moloney sarcoma virus (MSV) was injected i.m. into mice; immune lymphocytes were harvested from lymph nodes and sera were collected from immunized rats. Immune lymphocytes were incubated with cells of an MSV-transformed fibroblast line and cytotoxicity was observed. Immune lymphocytes alone caused a 33.5% reduction in target cell number compared to nonimmune lymphocytes. Pre-treatment of target cells with immune serum in high concentrations increased destruction of target cells by three of the sera. At lower concentrations, the serum was without effect and target cell destruction by three other sera was reduced. As sera were further diluted, cytotoxicity disappeared and continued to decline. The results suggested that synergistic cytotoxic effect of antiserum and lymphocytes from a sensitized host can take place when high concentrations of antisera are used to treat target cells.

3870 H-2 ANTIGENS ON MURINE LEUKEMIA CELLS AND VIRUSES. (E.) Dorfman, N. A.

Dept. Biol., Moscow St. U., USSR), V. N. Stepina and E. S. Ievleva. *Int J Cancer* 9(3):693-701, 1972.

Leukemia cells from Rauscher, Friend, Graffi, Mazurenko, Gross and SZ virus-induced mouse leukemias were mixed with antisera to H-2 (b, d and k) antigens, and the distribution of the antigens on leukemia cells and viruses was observed under

regardless of age. The 10^4 dose of KB cells produced only small nodules which regressed by two wk. African green monkeys given 10^7 KB cells developed tumors indistinguishable to those in rhesus monkeys in six of seven cases. KB cells produced no tumors in monkeys not pretreated with ALG, and normal diploid human cells produced no tumors in ALG-treated monkeys.

3873 THYMOCYTES FROM MICE IMMUNIZED AGAINST AN ALLOGRAFT RENDER BONE-MARROW CELLS SPECIFICALLY CYTOTOXIC. (E.) Grant, C. K. (Chester Beatty Res. Inst., Sutton, England), G. A. Currie and P. Alexander. *J Exp Med* 135(1):150-164, 1972.

C57BL mice were immunized against the L5178Y lymphoma of DBA/2 mice by i.p. injection of live tumor cells; cell suspensions of spleen, bone marrow and thymocytes were produced and used to treat L5178Y cells *in vitro*. Growth of L5178Y cells was inhibited in an immunologically specific manner by mixtures of bone marrow or spleen cells from non-immune mice and thymocytes from immune mice. The cytotoxicity of thymocytes and spleen or marrow cell mixtures increased as the concentration of immune thymocytes was increased. DNA synthesis in thymuses of C57BL mice fell after injection of L5178Y cells and remained reduced for seven days, the time at which thymocytes become capable of inhibiting tumor growth when mixed with nonimmune spleen or marrow cells. ^{51}Cr -release cytotoxicity tests of L5178Y cells treated with thymocyte-spleen-marrow cells indicated that tumor cell lysis was not the mechanism of growth inhibition by thymocyte mixtures. Cell-to-cell contact of growth-inhibiting cells and L5178Y cells was required for inhibition of growth of tumor cells. When thymocytes and bone marrow cells were irradiated separately and then mixed with L5178Y cells, thymus cells were found to be more radiosensitive than marrow cells; cytotoxicity of thymocytes was reduced by 400 R while cytotoxicity of marrow cells was only reduced by 2000 R. Immune thymocytes that were cultured with L5178Y cells as antigen and irradiated, did not lose their cytotoxicity, but immune irradiated thymocytes not cultured with antigen lost cytotoxicity. RNA synthesis was increased in thymocytes from immunized mice in the presence of antigen. Cell-free supernatants from immune thymocytes mixed with antigen contained a factor which rendered marrow cells cytotoxic; supernatants from nonimmune thymocytes and antigen, and from immune thymocytes alone, contained no such factor.

3874 COMPARISON OF AN IMMUNORESISTANT AND AN IMMUNOSUSCEPTIBLE ASCITES SUBLINE FROM MURINE TUMOR TA3: II. IMMUNOSENSITIVITY AND ANTIBODY-BINDING CAPACITY *IN VITRO*, AND IMMUNOGENICITY IN ALLOGENEIC MICE. (E.) Friberg, S., Jr. (Karolinska Inst. Med. Sch., Stockholm, Sweden). *J Nat Cancer Inst* 48(5):1477-1489, 1972.

Cells of the TA3-Ha and TA3-St sublines of the TA3

mouse mammary carcinoma from A/Sn mice were tested for susceptibility to antibody-mediated, complement-dependent cytotoxicity with mouse antisera prepared by allogeneic tissue injections. The TA3-Ha cells completely resisted cytotoxicity of sera while TA3-St cells were susceptible to humoral cytotoxicity. TA3-Ha cells could, however, be killed by heterologous antibodies. In ^{51}Cr -release tests of susceptibility to cell-mediated cytotoxicity, TA3-St cells were more susceptible than TA3-Ha cells. In tests of quantitative alloantibody absorption, TA3-St cells carried several times more surface histocompatibility H-2^a antigens than TA3-Ha cells; TA3-St cells could bind 20-30 times more specific antibodies than TA3-Ha cells. The low capacity of TA3-Ha cells to bind alloantibody may have been related to the antibody resistance of TA3-Ha cells. The two cell lines were compared for immunogenicity in mice; animals immunized with irradiated TA3-Ha or TA3-St cells were tested for humoral and cell-mediated immune responses. TA3-St cells were more immunogenic than TA3-Ha cells.

3875 INTERACTIONS OF IMMUNOGLOBULINS G AND M IN THE DETECTION OF THE MAMMALIAN C-TYPE VIRUS CROSS-REACTIVE ANTIGEN. (E.) Oroszlan, S. (Flow Lab., Rockville, Md.), D. Bova, R. Toni and R. V. Gilden. *Science* 176(4033):420-422, 1972.

To determine whether immunoglobulins IgG and IgM both enter into the reaction of antisera to the cross-reactive interspecific (gs-3) antigenic determinant carried by mammalian C-type viruses, antisera to murine leukemia virus and murine sarcoma virus were prepared in rabbits and rats, resp. The two antisera were separated into IgG and IgM fractions on Sephadex G-200, and their ability to detect the gs-3 determinant was observed in gel diffusion assays with various C-type virus antigens. Antisera which were not separated into IgG and IgM fractions showed a single precipitation line when reacted with C-type virus from hamster, cat and rat; this pattern of reactivity indicated that the reaction involved the interspecific gs-3 determinant. The IgM fractions of the antisera alone gave no reaction with C-type viral gs antigens, and the IgG fractions alone gave only reactions involving the gs-1 (species-specific) determinant. Recombination of IgG and IgM fractions resulted in recovery of gs-3 activity. The results indicate a novel synergistic effect of the IgG-IgM-containing fractions for demonstration of the cross-reactive gs-3 viral antigen in gel diffusion.

3876 EV-VIRUS ASSOCIATED SEROLOGY IN MALIGNANT DISEASE: ANTIBODY LEVELS TO VIRAL CAPSID ANTIGENS (VCA), MEMBRANE ANTIGENS (MA) AND EARLY ANTIGENS (EA) IN PATIENTS WITH VARIOUS NEOPLASTIC CONDITIONS. (E.) De Schryver, A. (Karolinska Inst., Stockholm, Sweden), G. Klein, G. Henle, W. Henle, H. M. Cameron, L. Santesson and P. Clifford. *Int J Cancer* 9(2):353-364, 1972.

Antibodies against Epstein-Barr virus (EBV)-induced

membrane antigens (MA), early antigens (EA) and viral capsid antigens (VCA) were studied by immunofluorescence in 249 sera obtained from African cancer patients. Patients included subjects with lymphoproliferative tumors, carcinomas and sarcomas. Patients with Burkitt's lymphoma and nasopharyngeal carcinoma were excluded, since it had been established that these conditions are associated with high levels of MA, EA and VCA antibodies against EBV. Blocking index (BI) values for test sera against MA, and serum anti-VCA titers were both low (BI < 0.50 and anti-VCA titers < 1:80) in patients with lymphoproliferative tumors. EA titers in lymphoproliferative cancer patients' sera were also low in most cases; 75% of sera were anti-EA negative. Among carcinoma patients BI values, anti-VCA titers and anti-EA titers were again generally low; only 12 of 92 sera tested were EA-positive. Anti-VCA titers, anti-EA titers and BI values for anti-MA were also low among sarcoma patients. These results confirmed the suggestion that malignant tumors other than Burkitt's lymphoma and nasopharyngeal carcinoma are not regularly associated with high anti-EBV antibody titers.

3877 TUMOR SUPPRESSION BY CELL WALLS OF *MYCOBACTERIUM BOVIS* ATTACHED TO OIL DROPLETS. (E.) Zbar, B. (Nat'l. Cancer Inst., Bethesda, Md.), H. J. Rapp and E. E. Ribl. *J Nat Cancer Inst* 48(3):831-835, 1972.

Guinea pigs were injected intradermally with cells of a diethylnitrosamine-induced hepatoma; the tumor cells were mixed with cell walls of bacillus Calmette-Guerin *Mycobacterium bovis* (BCG) attached to light mineral oil droplets. The oil-attached BCG walls mixed with tumor cells completely suppressed tumor growth. Oil droplets without BCG, cell walls alone, and cell walls in the presence of but not attached to oil droplets did not inhibit tumor growth. Guinea pigs in which tumor growth was suppressed were injected with line-10 hepatocellular carcinoma cells; delayed hypersensitivity skin reactions to line-10 cells developed, indicating that guinea pigs treated with oil-attached BCG and tumor cells had developed systemic immunity.

3878 *IN VITRO* LYMPHOCYTE RESPONSES TO MALIGNANT, BENIGN NEOPLASTIC AND NORMAL TISSUE EXTRACTS. (E.) Anderson, R. J. (Dept. Developmental Therap., U. Texas, Houston), C. M. McBride and M. M. Hersh. *Proc Soc Exp Biol Med* 140(2):465-470, 1972.

Extracts were prepared from 39 malignant melanomas, eight sarcomas, seven squamous cell carcinomas, three ovarian carcinomas, one Hodgkin's disease lymph node, one mammary carcinoma and one Wilms' tumor. Of the 60 patients involved, 57 had metastatic tumors. Stimulation of lymphocyte blastogenesis by extracts was observed using autochthonous lymphocytes, lymphocytes from other patients with similar tumors, and lymphocytes of normals.

Fifty-six percent of patients with metastatic tumors showed a significant blastogenic response to autochthonous tumor material; 60% also responded to autochthonous benign tumor extracts. In 50% of tests, patients' lymphocytes reacted significantly to extracts of normal tissue. The dose-response curves to benign and malignant tissue extracts were similar; similar doses induced similar degrees of response. The degree of blastogenesis in each responding patient increased as the protein concentration of normal and malignant tissues increased. Phytohemagglutinin (PHA) and streptolysin-O (SLO) induced greater blastogenic responses in patients' lymphocytes than did malignant or benign tissue extracts. Thirty-seven percent of normal subjects' lymphocytes and 60% of cancer patients' lymphocytes responded to allogeneic malignant tissue extracts. PHA and SLO induced greater responses than allogeneic tissue extracts. The evident lack of tumor specificity of the lymphocyte blastogenesis response suggests that this response is of limited use in the investigation of tumor immunity.

3879 *IN VITRO* STUDIES ON CELL-MEDIATED IMMUNITY FOLLOWING SURGERY IN MICE SENSITIZED TO SYNGENEIC MAMMARY TUMORS. (E.) Heppner, G. H. (Div. Bio-Med. Sci., Brown U., Providence, R.I.). *Int J Cancer* 9(1):119-125, 1972.

C3H/HeJ, C3HeB/FeJ, BALB/c and BALB/cfC3H mice were injected with syngeneic mammary tumor cells. When tumors became palpable, they were removed surgically, sham-operated but not removed, or left intact. Ten to 15 days after surgery, hosts were killed and lymph node cells (LNC) from tumor hosts were tested for cell-mediated immunity by colony-inhibition tests. LNC from mice whose tumors had been completely removed, or from mice which had received only sham surgery, were significantly more likely to show cellular immunity against their tumors than were LNC from mice with intact tumors. Cell-mediated immunity was seen in 12 of 13 mice in the complete tumor removal group, in 12 of 15 mice in the sham-operated group, and in seven of 17 mice with intact tumors. Sera taken from mice in these three experimental groups at one to five or 10-15 days after surgery were tested for ability to block cell-mediated immunity of LNC. Significant blocking activity was seen in five of six tests with sera from mice in the complete tumor removal group, in two of four tests with sera from mice in the sham-operated group, and in two of five tests with sera from mice with intact tumors. Blocking activity of sera had decreased in sera collected 10-15 days after surgery.

3880 SEROLOGICAL ANALYSIS OF CELL SURFACE ANTIGENS OF TUMORS INDUCED BY MURINE LEUKEMIA VIRUS. (E.) Herberman, R. B. (Nat'l. Cancer Inst., Bethesda, Md.). *J Nat Cancer Inst* 48(1):265-271, 1972.

Cells of Gross virus-induced W/Fu rat lymphoma and Gross virus-induced E6G2 leukemia of C57BL/6 mice, or cells of Rauscher virus-induced BALB/c mouse leukemia, were injected into syngeneic mice or rats to produce antisera against Gross or Rauscher virus-induced tumors. Cells of these and other tumors were reacted with antisera in ^{51}Cr -release cytotoxicity tests. The mouse anti-Gross serum reacted with Gross virus-induced rat and mouse tumor cells, but not with Rauscher virus-induced tumors or plasma cell tumors. Mouse anti-Rauscher serum reacted with Rauscher virus-induced tumor cells but not with Gross virus induced tumor cells. The W/Fu anti-Gross rat serum reacted strongly with Gross virus-induced mouse tumor cells, Rauscher virus-induced tumor cells, and plasma cell tumor cells. To define further the specificity of the W/Fu anti-Gross serum, absorption studies were performed. The antiserum was found to contain three antibodies to different cell surface antigens, including an antigen of plasma cell tumors and Gross, Rauscher and Moloney virus-induced tumors; an antigen of mouse Gross virus-induced tumors; and an antigen which appeared to be identical to the G_{IX} alloantigen. A benzo(a)pyrene-induced leukemia also showed some detectable antigenic reactivity with the W/Fu anti-Gross sera.

3881 ANTIGENICITY OF CLONES OF MOUSE PROSTATE CELLS TRANSFORMED *IN VITRO*. (E.)

Embleton, M. J. (McArdle Lab. Cancer Res., U. Wisconsin, Madison) and C. Heidelberger. *Int J Cancer* 9(1):8-18, 1972.

Colony inhibition tests, cytotoxicity tests and membrane immunofluorescence tests were performed on C3H mouse prostate cells transformed by 3-methylcholanthrene (MCA) or MCA-epoxide, or spontaneously transformed. Nontransformed mouse prostate cells did not grow upon injection into mice, and were not immunogenic. MCA-treated cells which did not transform were not immunogenic. Of 24 carcinogen-transformed cell lines, 19 were significantly antigenic in cell-mediated cytotoxicity and colony inhibition tests with lymph node cells from mice immunized against the respective cell lines. In cross-tests with antigenic transformed cell lines, all but two cell lines reacted only with the cell lines used for immunization and showed no cross-reactivity. Of eight spontaneously transformed C3H prostate cell lines, only two were antigenic; cell surface alloantigens were detected in the other six lines, although the lines were not immunogenic in syngeneic mice.

3882 DELAYED HYPERSENSITIVITY TO SIMIAN VIRUS 40 TUMOR CELLS IN BALB/c MICE DEMONSTRATED BY A RADIOISOTOPIC FOOT-PAD ASSAY. (E.) Paranjpe, M. S. (Natl. Cancer Inst., Bethesda, Md.) and C. W. Boone. *J Nat Cancer Inst* 48(2):563-566, 1972.

Male BALB/cAnN mice were immunized against SV40-

induced fibrosarcoma cells by s.c. inoculation of tumor cells. Immune and nonimmune mice were later challenged with SV40 tumor cells by foot-pad injection; immediately after challenge, mice were given ^{125}I -labeled syngeneic mouse serum protein i.p. Inoculation of tumor cells into the foot pad of immunized mice induced a delayed hypersensitivity reaction, as measured by the escape of ^{125}I -labeled protein into foot pad interstitial fluids. The reaction was specific; mice immunized with Freund's complete adjuvant did not show increased ^{125}I release after tumor cell challenge, nor did immunized mice "challenged" with normal syngeneic cells. Passive transfer of the delayed hypersensitivity reaction was accomplished with spleen cells, but not with serum, from immune mice.

3883 COMPLEMENT DEPENDENT INHIBITION OF RNA SYNTHESIS IN MALIGNANT MELANOMA CELLS.

(E.) Ikonopisov, R. L. (Oncol. Res. Inst., Sofia, Bulgaria). *Tumori* 57(4):247-285, 1971.

Malignant melanoma cells from 44 patients were labeled with tritiated uridine and reacted in the presence of active complement with sera from these patients (autologous sera), with sera from other melanoma patients (homologous sera) and with sera from normals. Uptake of tritiated uridine by tumor cells, which indicates RNA synthesis, was observed as a measure of cytotoxic antibody activity in sera. Complement-dependent inhibition of RNA synthesis (implying cytotoxic activity) was seen in 11 tests in which autologous sera were reacted with melanoma cells, and in five tests with homologous sera. Cytotoxic activity of sera diminished with the spread of melanoma.

3884 ANTIBODIES TO THE EPSTEIN-BARR VIRUS IN KIDNEY TRANSPLANT RECIPIENTS. (E.)

Spencer, E. S. (Inst. Med. Microbiol., U. Aarhus, Denmark) and H. K. Andersen. *Acta Med Scand* 191(1-2):107-110, 1972.

Sera from 30 kidney transplant recipients averaging 31 yrs of age were reacted in indirect immunofluorescence tests with EB-3 cells to detect anti-Epstein-Barr virus (EBV) antibody. The sera were taken at the time of kidney transplantation (initial sera) and for 120-357 days thereafter. All but one of the 30 initial sera contained detectable EBV antibodies. A fourfold rise in EBV antibody titer was seen in three patients during the serum observation period. Geometric mean EBV antibody titers in sera from patients without antibody titer rise was 90 (range from > 20-320); six patients had titers \geq 160. The three patients who showed significant rises in EBV antibody titer (two girls aged 11 and 18 and a 31 yr old man) also showed increases in heterophil antibody. Twenty-three EBV antibody-positive sera also showed anticytomegalovirus antibodies.

- 3885 FURTHER STUDIES ON TUMOR-SPECIFIC IMMUNITY INDUCED BY NONTUMORIGENIC MOUSE ASCITES TISSUE-CULTURE CELLS. (E.) Eng, C. P. (Dept. Cancer Res., U. Saskatchewan, Saskatoon, Canada) and J. F. Morgan. *Can J Microbiol* 18(6):775-781, 1972.

TA3 mouse ascites tumor cells which had lost their transplantability were used for inoculation in male A strain mice; immunizing inoculations were given weekly for three wks. A wk after the final injection, immunized mice were challenged with 10^2 - 10^6 virulent TA3 cells. All of 120 non-immunized mice given TA3 challenge cells developed fatal tumors. Immunization with nontumorigenic TA3 cells afforded 70% protection against challenge with 10^6 cells and 100% protection against lower challenge doses. Immunization by the i.p. route was more effective than immunization by the i.v. route, which in turn was more effective than i.m. immunization. Mice immunized with virulent TA3 cells which had been devitalized by iodoacetate treatment, lyophilization, sonication or freezing-and-thawing were not protected against challenge with virulent TA3 cells. Nontransplantable devitalized TA3 cells, however, afforded moderate protection against TA3 cell challenge. Nontumorigenic TA3 and 6C3HED ascites tumor cells induced 85-100% protection against challenge with solid tumor cells when immunization preceded tumor cell challenge. Non-tumorigenic TA3 cells also protected against a previous solid tumor cell challenge if immunization was performed by two wk after challenge; immunization three wk after challenge was not protective.

- 3886 IMMUNIZATION AGAINST SV40 VIRUS TUMORS: IMPORTANCE OF THE ROUTE OF INOCULATION. (Fr.) Dubreuil, R. (U. Montreal, Quebec, Canada), E. DiFranco and V. Pavilanis. *Int J Cancer* 9(2):426-434, 1972.

The effect of the route of inoculation in the vaccination of hamsters with SV40 virus or heterologous or homologous SV40-transformed cells against SV40 tumors was studied. Adult Syrian golden hamsters received s.c. injections, on days 0, 14, and 28, of one of the following: 1 ml un-diluted SV40 virus, 4-6 X 10^6 gamma-irradiated SV40-transformed hamster (CH4-Ry) cells, or culture medium 199 (control group). Ten days after the last injection, CH4 tumor cells were transplanted s.c. into the hamsters. At the end of a six month observation period, the hamsters vaccinated with the SV40 virus or the CH4-Ry cells showed a significantly greater resistance to the development of tumors than the control group. The experiment was repeated with another group of hamsters, giving i.p. injections, with the control group receiving normal hamster embryo (EHa) cells and an additional group of hamsters receiving heterologous (rabbit) SV40-transformed (RL3-T) cells. The results showed that while vaccination with the CH4-Ry and RL3-T cells did offer greater protection than in the control group, vaccination with SV40 virus did not. In all groups, including the controls, a greater

number of hamsters developed tumors than in the experiment in which the s.c. route of inoculation was used. In a further experiment, when hamsters received s.c. or i.p. inoculations of CH4-Ry or RL3-T cells after excision of transplanted tumors, there were fewer recurrences of tumors and metastases than in the control group, and again the protection was markedly higher with s.c. than i.p. injections. I.p. inoculation seemed to be especially effective in inhibiting the development of later metastases, particularly in the lung.

- 3887 CELL PROLIFERATION DURING IMMUNOLOGICAL PERTURBATION IN THREE TRANSPLANTED TUMOURS. (E.) Janik, P. (Inst. Cancer Res., Sutton, Surrey, England) and G. G. Steel. *Brit J Cancer* 26:108-114, 1972.

The timing of the mitotic cycle was studied by the percent labeled mitosis technique in three tumors: the L5178Y lymphoma growing in DBA/2 mice; the BICR/A3 osteosarcoma growing in the leg of a rat; and the BICR/A12 adenocarcinoma, a rat mammary tumor. Growth of the L5178Y and BICR/A3 tumors was completely arrested by injection of host mice with irradiated tumor cells and X-irradiation of host rats, resp. Growth of the BICR/A12 tumor was retarded by injecting the hosts with Freund's complete adjuvant. Despite arrested or retarded growth of the three tumors, the percent labeled mitosis levels in tumor cells from animals with inhibited tumors were not significantly different from the percent labeled mitosis levels in untreated animals with growing tumors. Even if tumor growth was completely arrested by an immunological response in the hosts, there was evidently little change in the timing of cell division in those tumor cells which continued to proliferate. It is suggested that growth retardation was associated with a reduction in the proportion of proliferating tumor cells and/or with a reduction in the rate of cell production.

- 3888 CELLULAR REACTIONS AGAINST BURKITT LYMPHOMA CELLS: III. EFFECTOR CELL ACTIVITY OF LEUKOCYTES STIMULATED *IN VITRO* WITH AUTOCHTHONOUS CULTURED LYMPHOMA CELLS. (E.) Golub, S. H. (Dept. Tumor Biol., Karolinska Inst., Stockholm, Sweden), E. A. J. Svedmyr, J. F. Hewetson, G. Klein and S. Singh. *Int J Cancer* 10:157-164, 1972.

Lymphoblastoid culture lines (LCL) were established from tumor biopsies from four Burkitt's lymphoma patients. Peripheral blood leukocytes from the same patients were mixed with autochthonous LCL cells and colony inhibition (CI) tests and tests of leukocyte stimulation by LCL cells were performed. When leukocytes were tested against autochthonous LCL target cells without prior stimulation of leukocytes by LCL cells, no significant CI activity was seen. When leukocytes were mixed with mitomycin C-stimulated autochthonous LCL cells, leukocytes were stimulated (as measured by ^3H -thymidine uptake), sometimes by

as much as three- to twenty-fold. Leukocytes stimulated by incubation with autochthonous or allogeneic LCL cells were mixed with allogeneic or autochthonous LCL cells and CI activity was observed. Leukocytes stimulated with autochthonous LCL cells showed strong CI activity, against both autochthonous and allogeneic LCL target cells. Stimulated leukocytes showed considerably less CI activity against a non-Burkitt lymphoma-derived target cell line. Autochthonous fibroblasts were ineffective as stimulator cells.

- 3889 AUTOIMMUNE REACTIONS IN UVEAL MELANOMA.
(E.) Rahi, A. H. S. (Inst. Ophthalmol., U. London, England). *Brit J Ophthalmol* 55(12):793-803, 1971.

Sera from 21 patients with uveal melanoma were tested for antibodies against their own tumors using cytotoxicity tests and sometimes RNA synthesis inhibition and immunofluorescence tests. Tumor cells were cultured and reacted with autochthonous sera alone or with complement. Seven of 21 tumors tested showed complement-dependent cytotoxic antibody reactions. In four cases where RNA synthesis inhibition was tested, complement-dependent inhibition of RNA synthesis was seen for autochthonous sera with two tumors. Each of these sera had showed cytotoxic antibody in the preceding test. Three cytotoxic sera gave positive results when tested for membrane immunofluorescence against their respective tumors.

- 3890 THE DISTRIBUTION OF HL-A LEUKOCYTE ANTIGENS IN SINGAPORE CHINESE, MALAYS, AND INDIANS.
(E.) Ting, A. (Dept. Surg., U. Melbourne, Australia), G. B. Wee, M. J. Simons and P. J. Morris. *Tissue Antigens* 1(6):258-264, 1971.

Venous blood from 146 Chinese, 104 Malays, and 85 Indians, all residents of Singapore, were tested for 19 HL-A antigens from the two HL-A loci. One antigen from each locus was found to occur more frequently in each ethnic group relative to the other two groups. HL-A11 and W10 were more frequent in Chinese; HL-A9 and W15 were more frequent in Malays; and HL-A1 and W17 were more frequent in Indians. HL-A1 was virtually absent from Chinese, showed low frequencies in Malays, and a high frequency in Indians. This confirmed that HL-A1 is a "Caucasian" antigen. Delta (linkage disequilibrium between the two loci) values for pairs of phenotypically detected antigens, one from each locus, were calculated. No pairs of antigens showed significant associations in Malays. In Chinese, HL-A2 and HL-A12, HL-A9 and HL-A5, HL-A9 and W17, and HL-A11 and W15 were associated. In Indians, HL-A1 and W17, HL-A2 and W17, and HL-A3 and W5 were associated.

- 3891 TRANSPLANTATION ANTIGENS AND MALIGNANT LYMPHOMAS IN MAN: FOLLICULAR LYMPHOMA, RETICULUM CELL SARCOMA AND LYMPHOSARCOMA. (E.)

Forbes, J. F. (Dept. Surg., U. Melbourne, Australia) and P. J. Morris. *Tissue Antigens* 1(6):265-269, 1971.

HL-A antigen typings were performed on peripheral blood lymphocytes from 134 malignant lymphoma patients, including 50 patients with lymphosarcoma, 56 with follicular lymphoma and 28 with reticulum cell sarcoma. Most patients were in remission; all were Caucasian. A highly significant association was found between the diseases and the specificity HL-A12 ($p < 0.005$). The association was most apparent in the follicular lymphoma group, where the frequency of HL-A12 antigen was 62.5%. The increased frequency of HL-A12 in lymphosarcoma and reticulum cell sarcoma patients was not statistically significant.

- 3892 HL-A LEUKOCYTE ANTIGEN STUDIES IN WOMEN WITH GESTATIONAL TROPHOBLASTIC NEOPLASMS.
(E.) Lewis, J. L., Jr. (Memorial Hosp. Cancer Allied Dis., New York, N.Y.) and P. I. Terasaki. *Trans Amer Gynec Soc* 94:85-92, 1971.

Fifteen women with gestational choriocarcinoma developing in pregnancy resulting in a living child were studied. In each case, the husband and the child associated with the pregnancy resulting in choriocarcinoma were typed for HL-A leukocyte antigens. In addition, 23 of 25 other offspring were also studied. Eleven of the 15 women had tumor metastases at the time of treatment. Only one of the 11 showed HL-A antigen compatibility with the offspring associated with choriocarcinoma. The tumor of this subject metastasized before delivery. One other patient with metastases showed possible HL-A compatibility with the offspring associated with choriocarcinoma. In four patients with nonmetastatic disease, one was compatible with the fetus associated with choriocarcinoma. Eleven other offspring (not associated with choriocarcinoma) had HL-A patterns identical with the offspring associated with choriocarcinoma. Sixteen families in which the mother developed a gestational trophoblastic neoplasm in a pregnancy which did not result in a living infant were also studied. In eight of the 16 women with metastatic disease, there was a possibility that mating produced a fetus compatible for HL-A pattern with the mother in three cases. There were two possibly compatible fetuses in eight cases of nonmetastatic disease. This incidence was higher than would have been expected for random mating. There was no correlation between HL-A compatibility and presence of metastases.

- 3893 CELL-MEDIATED IMMUNITY DIRECTED AGAINST A SYNGENEIC PLASMA CELL TUMOR IN THE MOUSE. DETECTION BY MACROPHAGE-MIGRATION INHIBITION TEST. (E.) Poupon, M.-F. (Sci. Cancer Res. Inst., Villejuif, France) and G. Lepinat. *J Nat Cancer Inst* 48(5):1297-1301, 1972.

Cells of the LA3 plasmacytoma of BALB/c mice were mixed with splenic lymphocytes from mice immunized

against LA3 and with peritoneal exudate cells (PEC) from normal and immunized mice. The migration of PEC cells was observed by the macrophage-migration inhibition test. The migration of PEC from normal mice in the presence of splenic lymphocytes from immunized mice was significantly inhibited when LA3 cells was present. The average inhibition was 50% of control (i.e., normal PEC plus LA3 cells and normal lymphocytes). Migration of PEC from immunized mice was also inhibited in this system. Immune lymphocytes from allogeneic C3H and C57BL mice in the presence of LA3 cells also inhibited PEC migration. The migration of BALB/c spleen cells was inhibited under the same conditions as was PEC migration. The PEC and spleen cell migration inhibition was mediated by a soluble factor which could be demonstrated in supernatants from mixtures of immune lymphocytes and LA3 cells.

3894 IMMUNOGENICITY OF VARIOUS FORMS OF H-2 ANTIGENS AS DETECTED BY THE GROWTH RATE OF AN ALLOGENEIC TUMOUR. (E.) Hilgert, I. (Czechoslovak Acad. Sci., Prague), H. Kristofova and S. Stoyanov. *Folia Biol* 17(6):353-359, 1971.

A/Ph and B10.D2 mice were given i.p. injections of irradiated (20,000 R) allogeneic spleen cells or cell-free spleen extracts, or i.p. injections of irradiated cells or extracts that had been submitted to freezing and thawing or lyophilization. The immunogenicity of the different forms of cell and extract H-2 antigens was measured by observing the growth of an allogeneic sarcoma grafted onto mice pretreated with spleen cells. Irradiation eliminated the proliferative capacity of spleen cells but did not affect their ability to absorb H-2 antibody. Irradiation produced maximal immunogenicity in spleen cells; growth of sarcomas in mice given irradiated spleen cells alone was impaired compared to growth of sarcomas in mice given freeze-thawed or lyophilized irradiated cells. Freeze-thawing reduced spleen cell immunogenicity more than lyophilization, but the difference was not essential. On cell-free extracts, the immunogenicity-reducing effect of freezing and thawing and lyophilization was weaker than but similar to that on irradiated cells.

895 HSV-2 ANTIGENS ABSENT FROM BIOPSIED CERVICAL TUMOR CELLS: A MODEL CONSISTENT WITH LATENCY. (E.) Aurelian, L. (Johns Hopkins Sch., Baltimore, Md.), J. D. Strandberg and H. J. Davis. *Proc Soc Exp Biol Med* 140(2):404-408, 1972.

Frozen sections and biopsy specimens from 29 patients with preinvasive and invasive cervical carcinoma were reacted in indirect immunofluorescence tests with a rabbit immune serum against the herpesvirus type-2 (HSV-2) antigen. No fluorescence reactions were seen in any of the neoplastic material. Electron microscopy revealed no herpesvirus virions or cytoplasmic changes associated with synthesis of herpesvirus antigens in cervical carcinoma biopsy material. How-

ever, 25 of 29 patients' exfoliated cervical carcinoma cells showed cytoplasmic HSV-2 fluorescence. Nuclear fluorescence was not seen. Virus particles were not seen in exfoliated cell material, but cytoplasmic changes associated with herpesvirus antigen synthesis were observed. These results demonstrate that biopsied cervical tumor cells harbor the HSV-2 genome in a repressed state.

3896 STUDIES ON THE ANTIGENICITY OF RADIATION-INDUCED MURINE OSTEOSARCOMATA. (E.)

Moore, M. (Charles Salt Res. Ctr., Oswestry, Shropshire, England) and D. E. Williams. *Brit J Cancer* 26:90-98, 1972.

Cells from 15 osteosarcomas induced in CBA mice by injection of ^{90}Sr were irradiated (15,000 rads) and implanted s.c. into syngeneic mice; immunizing grafts of irradiated tumor cells were given three times at intervals of ten to 21 days. In some cases, osteosarcoma grafts growing in mice were excised to immunize hosts to the tumor. Mice immunized against osteosarcoma by implantation with irradiated cells or by excision of a tumor graft were given 400 rads whole-body X-irradiation before challenge with osteosarcoma cells. Of 15 osteosarcomas, six were immunogenic in that the number of challenge tumor takes was less in hosts immunized by grafts of irradiated tumor cells than in unimmunized mice. However, the resistance induced to osteosarcomas was of a relatively low order. Nine tumors were either not immunogenic or were immunogenic to a negligible degree only. Only one osteosarcoma was immunogenic when inoculated as a challenge in a mouse immunized by excision of an osteosarcoma graft. Moreover, transplantation resistance in this case was weak. Sera from mice immunized against radiation-induced osteosarcomas by implantation of irradiated tumor cells gave no significant immunofluorescence reactions when reacted against cells of the same osteosarcoma.

3897 EFFECT OF IMMUNE FACTORS ON THE MOTILITY OF LYMPHOMA CELLS. (E.) Cochran, A. J.

(Dept. Tumor Biol., Karolinska Inst., Stockholm, Sweden), E. Klein and R. Keissling. *J Nat Cancer Inst* 48(6):1657-1661, 1972.

The effect of antisera on the migration of Moloney virus-induced YAC lymphoma cells, collected from A/Sn mice bearing the tumor, in Eagle's minimum essential medium was studied. Both anti-H-2a antiserum and an anti-Moloney virus antiserum markedly inhibited YAC cell migration when added to the tissue culture medium in which YAC cells were migrating. The anti-H-2a serum was more active in inhibiting YAC migration than the anti-Moloney antiserum. The inhibition of YAC migration by the antisera paralleled antisera activity in complement-dependent cytotoxicity tests with YAC cells as target. This suggested that YAC migration inhibition by antisera is independent of exogenous complement. The inhibitory effect of antisera was removed by absorbing sera with YAC cells.

YAC cells preincubated with antisera before migration testing showed considerably reduced migration. YAC cells preincubated with nonimmune normal A/Sn mouse serum migrated better than YAC cells not preincubated with any serum. YAC migration was inhibited by cell-free ascitic fluid from YAC lymphoma-bearing mice, but was not affected by fluid from tumor-free mice.

- 3898 CELLULAR CYTOLYSIS *IN VITRO*: MECHANISMS UNDERLYING A QUANTITATIVE ASSAY FOR CELLULAR IMMUNITY. (E.) MacPherson, B. R. (Nat'l. Cancer Inst., Bethesda, Md.) and Y. H. Pilch. *J Nat Cancer Inst* 48(6):1619-1627, 1972.

Guinea pigs were immunized against a methylchloanthrene-induced transplantable liposarcoma (MCA-A) or an osteosarcoma (MCA-25) by injection of tumor cell inocula. Immune lymphocytes were collected from the spleen, lymph nodes and blood of immune guinea pigs and introduced into cultures containing ³H-thymidine-labeled MCA-A or MCA-25 cells. Immune cytotoxicity of tumor cells was assayed by determining radioactivity of adherent tumor cells. Allogeneic and syngeneic immune lymphocytes from spleen, lymph nodes and blood produced detectable immune cytotoxicity at all dilutions tested. Immune cytotoxicity by syngeneic immune lymphocytes was at a lower level than that effected by allogeneic lymphocytes. The interaction of immune lymphocytes and target cells failed to cause lysis of immunologically unrelated target cells in the same culture. Serum from immune guinea pigs did not lyse MCA-A or MCA-25 cells. "Immune" cell-free supernatants from mixed immune lymphocytes and MCA-A cells did not lyse MCA-A cells. However "immune" supernatants combined with normal (nonimmune) guinea pig lymphocytes did produce slight cytotoxicity in MCA-A cells.

- 3899 CULTURES FROM ADULT RAT LIVER CELLS: II. DEMONSTRATION OF ORGAN-SPECIFIC CELL SURFACE ANTIGENS ON CULTURED CELLS FROM NORMAL LIVER. (E.) Iype, P. T. (Christie Hosp. Manchester, England), R. W. Baldwin and D. Graves. *Brit J Cancer* 26(1):6-9, 1972.

Freshly isolated liver cell lines from male Wistar rats, and epithelial and non-epithelial cell lines in culture for 60-182 days, were reacted with anti-normal rat liver membrane antiserum (ANLM), anti-liver cell antiserum, anti-plasma membrane antiserum (APM), or anti-normal liver *h* protein antiserum. The presence of liver-specific antigens on the surfaces of fresh as well as cultured rat liver cells was demonstrated by positive membrane immunofluorescence reactions of these cells with ANLM. APM also reacted strongly with freshly isolated cells. Antigens were also detected on enzyme-treated liver cells in which parenchymal cells had been disaggregated from liver tissue.

- 3900 MONOCLONAL MEMBRANE IMMUNOGLOBULINS IN CHRONIC LYMPHOCYTIC LEUKEMIA. (Fr.)

Preud'homme, J. L. (St. Louis Hosp. Blood Dis. Res. Inst. Paris, France), M. Klein, P. Verrdust and M. Seligmann. *Rev Eur Etudes Clin Biol* 16(10): 1025-1031, 1971.

Peripheral (and in some cases, medullary or ganglionic) lymphocytes from 13 patients with chronic lymphocytic leukemia were examined by direct immunofluorescence on viable cell suspensions for the presence of membrane-bound immunoglobulins. In 11 cases of lymphocytic leukemia lacking serum monoclonal immunoglobulins, 80-95% of the circulating lymphocytes carried monoclonal immunoglobulin chains. These were usually made up of μ chains, associated more often with κ than λ chains. The presence of monoclonal IgG was found in one case and monoclonal IgA, in another case also. These lymphocytes were considered to represent the proliferation of B lymphocytes which has been arrested in the maturation process. No membrane-bound immunoglobulins were found on the lymphocytes of two patients, suggesting a proliferation of thymus-dependent (T) lymphocytes. In two cases of chronic lymphocytic leukemia associated with serum monoclonal immunoglobulins, the finding of both membrane and intracytoplasmic immunoglobulins demonstrated a bclonal proliferation. In one case both IgA and IgM markers shared λ light chains whereas in the other case, the two immunoglobulins had different heavy and light chains. The detection of membrane-bound monoclonal immunoglobulins as markers of B cells could be useful in the early diagnosis of chronic lymphocytic leukemia.

- 3901 IMMUNOSUPPRESSION BY BISDIOXOPIPERAZINES: EFFECTS ON ANTIBODY-FORMING CELLS AND SERUM TITERS. (E.) Tucker, D. F. (Imperial Cancer Res. Fund, London, England) and M. D. Finch. *J Nat Cancer Inst* 48(5):1347-1354, 1972.

Male random-bred Swiss-Schneider ICRF mice were given i.p. injections totaling 15 mg/kg of 1,2-bis(3,5-dioxopiperazin-1-yl) ethane (ICRF 154) or (\pm)-1,2-bis(3,5-dioxopiperazin-1-yl) propane (ICRF 159); administration of 154 or 159 began three days before and ended two days after immunization of mice with sheep red blood cells (SRBC). With this injection schedule, the plaque-forming cell (PFC) response in spleens of treated mice was inhibited to about the same degree by 154 and 159 as it was by cyclophosphamide (CPA). There was good correlation between drug dose and inhibition of PFC response; the extent of PFC inhibition increased proportionally with increasing doses of 154 or 159. Similar treatment schedules with 154 or 159 also interfered with the primary immunization to bovine serum albumin, as judged by weakened secondary immune responses. The greatest interference was seen when 154 or 159 was given daily from the time of primary antigen exposure. The time dependence of immunosuppression by 154 or 159 was studied in more detail by use of the PFC assay system only. 154 or 159 were most

effective in immunosuppression when given 48 or 72 hr after SRBC (60% suppression of PFC). This effect was similar to but less striking than immunosuppression produced by CPA (83 and 79% depression of PFC at 48 and 72 hr after SRBC, resp.) When administered before SRBC, CPA gave only slight PFC inhibition; 159 gave 42% inhibition when given 72 hr before SRBC, and 154 was not inhibitory when given at 72 hr before SRBC.

3902 SPONTANEOUS TRANSFORMATION OF RAT CELLS AFTER LONG-TERM *IN VITRO* CULTIVATION AND THE "SWITCH-ON" OF A NEW COMPLEMENT-FIXING ANTIGEN. (E.) Rhim, J. S. (Natl. Inst. Hlth., Bethesda, Md.), M. L. Vernon, R. J. Huebner, H. C. Turner, W. Lane and R. V. Gilden. *Proc Soc Exp Biol Med* 40(2):414-419, 1972.

Morphological alterations and an abnormally increased growth pattern were seen in S-1193h rat embryo cells in culture at the 45th subculture. Foci of transformed cells appeared which consisted of randomly oriented, criss-crossed spindle-shaped cells. In complement-fixing (CF) tests with antisera produced in rats carrying Moloney sarcoma virus (MSV)-induced transplanted sarcomas, transformed rat embryo cells at the 51st subculture showed the CF antigen reactive with the anti-MSV serum. No viruses or virus-like particles were detected in transformed rat embryo cell cultures. Progressive transplantable tumors were readily produced in newborn rats by inoculation with spontaneously transformed rat embryo cells. Cultured tumor cells and rat tumors contained antigens reactive with the MSV rat antisera but not antigens reactive with the gs-1-specific guinea pig antisera. Rat tumors also reacted with sera from rats bearing tumor induced by polyoma virus-transformed rat embryo cells. While the antigen in the spontaneously transformed cells was similar to the antigen in polyoma-transformed cells, it appeared much earlier in polyoma-transformed cells.

3903 QUANTITATIVE STUDIES ON THE BINDING OF SYNGENEIC ANTIBODY TO THE SURFACE ANTIGENS OF AKR-VIRUS-INDUCED RAT LYMPHOMA CELLS. (E.) Boone, C. W. (Natl. Inst. Hlth., Bethesda, Md.), P. R. Brandchaft, D. N. Irving and R. Gilden. *Int J Cancer* 9(3):685-692, 1972.

Suspensions of Gross virus-induced rat lymphoma cells were treated with antisera against the lymphoma; mixed normal and immune sera mixed with lymphoma cells had been labeled with ^{125}I or ^{131}I , a technique permitting precise estimations of nonspecific antibody adsorption. The binding of antibody to the G cell surface antigen (GCSA) of lymphoma cells was determined by immune serum titration and cell titration; the number of antigenic sites per lymphoma cell and per bond was calculated. The number of antibody molecules bound to GCSA sites per lymphoma cell was 6.90×10^6 and the number of antigen sites

on each cell was $11,300$ sites/ μ^2 . The average equilibrium constant of the GCSA-antibody association reaction was 6.54×10^6 l/mole. The ΔF° (mean binding affinity) value of binding for the antibody-surface antigen bond was -9.17 Kcal/mole and the dissociation rate constant (k_2) of bound antibody at 0°C was 3.67×10^{-5} /sec.

3904 SPECIFIC ENHANCEMENT OF TRANSPLANTATION IMMUNITY WITH HEAT-KILLED *MYCOBACTERIUM BUTYRICUM* AND IMMUNIZING EXTRACTS FROM ADENOVIRUS 12-INDUCED TUMOUR CELLS. (E.) Rees, R. C. (Virus Res. Lab., U. Sheffield, England) and C. W. Potter. *Brit J Cancer* 26:139-140, 1972.

CBA mice were inoculated with cell suspensions from an adenovirus 12-induced transplantable CBA mouse tumor once a wk for three wk; some mice were given tumor cells together with heat-inactivated *Mycobacterium butyricum*. Two wk after the last immunizing inoculation, mice were challenged with viable tumor cells from the same tumor. The incidence with tumor cells and *M. butyricum* was significantly lower than in mice immunized with tumor cells alone. Forty-four percent of mice given tumor cells alone developed tumors while 5.5% of mice given tumor cells plus *M. butyricum* developed tumors. *M. butyricum* alone did not protect against tumor cell challenge; tumor incidences of 100% and 78% were obtained in two groups of controls.

3905 CELLULAR IMMUNITY TO RENAL CARCINOMAS IN MAN. (E.) Bubenik, J. (Inst. Exp. Biol. Genetics, Czechoslovak Acad. Sci., Prague), J. Jakoubkova, P. Krakora, M. Baresova, P. Helbich, V. Viklicky and V. Malaskova. *Int J Cancer* 8:503-513, 1971.

A microassay in disposable tissue-culture plates was used to demonstrate a cell-mediated immune response against human renal adenocarcinomas. Leukocytes from 12 of the 19 patients with renal carcinoma were cytotoxic for autochthonous and allogeneic renal carcinoma cells *in vitro*. No reproducible cytotoxic effects were produced by leukocyte suspensions from patients with pulmonary or mammary carcinoma, or by leukocytes from healthy and non-neoplastic control subjects. No cytotoxicity was observed when cells of unrelated tumors, mesothelioma and urinary bladder carcinoma were used as target cells for leukocytes from a patient who reacted positively against autochthonous renal carcinoma cells. The results indicate that human renal adenocarcinomas possess tumor-associated antigens which cross-react with each other. Cytological and electron microscopic characteristics of cultivated renal carcinoma cells are described.

3906 EFFECTS OF PIG LEUKOCYTES ON MOUSE LYMPHATIC LEUKEMIA. (E.) Hill, G. (U. Colorado Med. Ctr., Denver), K. Littlejohn, G. Kelly, R.

Atkins, J. Greer and B. Eiseman. *J Surg Oncol* 3(5): 569-579, 1971.

AKR/J mice were injected i.p. with BW 5147 lymphatic leukemia cells and with blood or spleen leukocytes from pigs immunized against BW 5147 leukemia. In some cases, tumor cells and pig leukocytes were incubated together and injected into mice together; in other cases, tumor cells were injected, followed by pig leukocytes. The increase in life span ILS, defined as percentage of improvement in mean survival time of treated as compared to untreated mice) was observed. Significant prolongation of ILS was seen in 8 of 13 experiments in which leukemic cells were incubated with tumor-immune pig leukocytes prior to injection into mice. ILS was prolonged when tumor cells were incubated with immune leukocytes from perfused pig spleens, from live pig spleens or from pig peripheral blood. ILS was not increased when leukemic cells were incubated with immune leukocytes from splenic perfusates from pigs. Significant ILS prolongation was not seen when tumor cells were incubated with nonimmune pig leukocytes or with leukocytes immunized against normal mouse lymphoid tissue. Also, no therapeutic benefit was apparent when tumor injections in mice were followed by treatment with tumor-immune pig leukocytes or normal pig leukocytes.

3907 SUPPRESSION OF *IN VIVO* IMMUNE RESPONSES IN THE GUINEA PIG BY PHYTOHEMAGGLUTININ.

(E.) Pilch, B. Z. (Natl. Cancer Inst., Bethesda, Md.), H. R. Gertner and P. B. Chretien. *J Surg Oncol* 3(5):525-532, 1971.

Guinea pigs were injected i.p. with phytohemagglutinin (PHA, 1 ml of an 0.85% solution/kg body wt) daily beginning two days before injection of antigenic bovine gamma globulin (BGG), skin grafting or injection of antigenic tuberculin D. Immune responses to antigens and skin grafts were observed. There was a significant delay in the rise of anti-BGG titers in all of seven PHA-treated guinea pigs two wks after BGG; the mean log₂ titer of untreated animals was ten while that of PHA-treated animals was 5.5. Skin allograft survival was prolonged from a mean of 10.6 days in untreated guinea pigs to a mean of 13.1 days in PHA-treated animals. The delayed cutaneous hypersensitivity reaction to tuberculin in guinea pigs immunized with BCG was completely suppressed in seven of eight PHA-treated guinea pigs.

3908 DETECTION OF AN ANTIGEN ASSOCIATED WITH ACUTE LEUKEMIA. (E.) Mann, D. L. (Natl. Cancer Inst., Bethesda, Md.), G. N. Rogentine, R. Halterman and B. Leventhal. *Science* 174(4014):1136-1137, 1971.

Antiserums to a purified cell membrane component from a Burkitt's lymphoma tissue culture cell line were produced in rabbits. These antiserums were cytotoxic to peripheral white blood cells from 8 of 15 patients with acute leukemia and 5 of 41 relatives,

but not to peripheral white blood cells from leukemia patients in clinical remission or from normal individuals. These antiserums appear to be detecting an acute leukemia associated antigen or antigens.

3909 IMMUNOLOGIC ENHANCEMENT OF ALLOGENEIC TUMOR GROWTH WITH SOLUBLE HISTOCOMPATIBILITY-2 ANTIGENS. (E.) Law, L. W. (Natl. Cancer Inst., Bethesda, Md.), E. Appella, P. W. Wright and S. Strober. *Proc Nat Acad Sci USA* 68(12):3078-3082, 1971.

Soluble, partially purified, histocompatibility antigens that were obtained from the membranes of A/J spleen cells have been assayed for their capacity to elicit immunologic enhancement of two tumors of A-strain origin: YAA-C1 and Sarcoma I. Crude membrane material and a partially purified, soluble antigen that were contained in a specific fraction, obtained after chromatography on a Sephadex G-150 column, elicited enhancement: this fraction has been shown to contain immunogenic histocompatibility-2^a antigens as well as alloantigenic specificities that were detected serologically. Another soluble fraction did not induce enhancement; this fraction has been shown to contain antigens other than H-2. Passive enhancement of both tumors was achieved with antisera produced in allogeneic mice that were inoculated with crude membrane material or with a fraction obtained by Sephadex G-150 chromatography. These antisera contained cytotoxic and/or hemagglutinating antibodies. Immunologic enhancement was specific. A readily enhanceable tumor, Py 89, of C57BL origin was not enhanced with anti-H-2^a antisera. These results suggest strongly that all important H-2^a transplantation antigenic determinants of spleen cells can be recovered by partial papain digestion and fractionation on a Sephadex G-150 column.

3910 TUMOR-ASSOCIATED ANTIGEN IN PATIENTS WITH CARCINOMA OF THE COLON. (E.) Lo Gerfo, P. (Columbia U., Coll. Physicians Surg., New York, N.Y.), F. Lo Gerfo, F. Herter, H. G. Barker and H. J. Hansen. *Amer J Surg* 123:127-131, 1972.

3911 SPLEEN WEIGHT IN RATS DURING TUMOUR GROWTH AND IN HOMOGRAFT REJECTION. (E.) Blamey, R. W. (Inst. Cancer Res., Cardiff, England) and D. M. D. Evans. *Brit J Cancer* 25(3):527-532, 1971.

3912 THE PRESENCE OF AN ANTIGEN PROTEIN IN THE URINE OF CANCER PATIENTS REVEALED BY IMMUNOELECTROPHORESIS; ITS CONFIRMATION BY IMMUNODIFFUSION. (Fr.) Aron, M. (Sch. Med. Strasbourg, France) and J.-P. Isaac. *C R Acad Sci [D] (Paris)* 275:305-308, 1972.

3913 DEPENDENCE OF THE ANTIBODY FORMING CELL NUMBER ON THE SPLEEN CELL PROLIFERATION STAGES, INDUCED EXPERIMENTALLY IN MICE. (Jap.)

3936 NEOPLASTIC TRANSFORMATION *IN VITRO* OF A CLONE OF ADULT LIVER EPITHELIAL CELLS INTO DIFFERENTIATED HEPATOMA-LIKE CELLS UNDER CONDITIONS OF NUTRITIONAL STRESS. (E.) Borek, C. (Columbia U., New York, N.Y.). *Proc Nat Acad Sci USA* 69(4): 956-959, 1972.

A cloned line of epithelial-like cells was established from the normal liver of a three-month-old buffalo rat and maintained in contact-inhibited monolayers by continuous subculture for a period of 8 months. After ten consecutive days in culture without feeding, the cells appeared as a tightly packed monolayer in which mitosis was observed. Within 30-40 days of the start of the experiment, isolated loci of refractile cells went into mitosis and began to form a second layer in 45 of the 50 experimental plates; no such loci were observed in the controls. Five to seven days after the appearance of the transformed cells, the whole petri dish was covered by a multilayer of cells. Analysis of the transformed cells showed that these cells had: maintained their ability to synthesize serum proteins, developed morphological changes, sustained a decreased adhesiveness to one another, were able to grow in semi-soft agar, acquired agglutination characteristics in the presence of heat germ agglutinin and concanavalin A and lost the inhibition of replication on contact with other cells. This experiment presents a simple device for producing transformation *in vitro*.

3937 THE KARYOTYPE OF BONE MARROW CELLS FROM CATTLE WITH PERSISTENT LYMPHOCYTOSIS AND IN LYMPHOSARCOMA. (E.) Cerny, L. (U. Sch. Vet. Med., Brno, Czechoslovakia), L. Lojda and R. Rademacher. *oplasma* 19(3):217-225, 1972.

Bone marrow cells were aspirated from five cows with lymphocytosis and from two cows with lymphosarcoma. Chromosome counts were made on bone marrow cells. In cows with lymphocytosis, bone marrow cell ploidy resembled that in normal healthy cow marrow; hypodiploidy was seen but hyperploidy was rare. The ratio of dividing to resting cells in marrow of cows with lymphocytosis ranged from 1:238 to 1:125. One of two cows with lymphosarcoma showed near-tetraploid bone marrow cells. In this cow, the ratio of near-tetraploid to diploid leukocytes in marrow was 1:20.

3938 CHANGES IN THE STRUCTURAL ORGANIZATION OF THE SURFACE MEMBRANE IN MALIGNANT CELL TRANSFORMATION. (E.) Ben-Bassat, H. (Weizmann Inst. Sci., Rehovot, Israel), M. Inbar and L. Sachs. *Membrane Biol* 6(3):183-194, 1971.

A comparison was made between the size of normal Syrian hamster embryo cells grown in "adult 1 calf serum", "adult 2 calf serum" or fetal calf serum and the size of cells transformed *in vitro* by polyoma virus or dimethylnitrosamine and grown in the same media. Transformed cells did not acquire the growth

pattern of normal cells in any of the three culture media. The relationship between cell size, binding sites and agglutinability in cells under different growth conditions was then examined using the Concanavalin A (Con A) agglutination assay and the radioactive method of counting binding sites. Adult 1 calf serum caused transformed hamster cells to bind a higher number of Con A molecules per cell than normal cells. The increase in the number of molecules bound was associated with an exposure of cryptic sites in transformed cells and to a lesser extent with a slight decrease in size of transformed cells. Both adult 2 calf serum and fetal serum permitted normal and transformed cells to bind a similar number of Con A molecules; only the transformed cells however were agglutinated by Con A. In adult 2 calf serum, the gain in agglutinability was associated with a concentration of exposed sites due to a decrease in cell size; there was no evidence of exposure of cryptic sites. In fetal serum, the gain in agglutinability in transformed cells was not due to differences in cell size but presumably to a rearrangement of exposed sites, resulting in clustering of sites.

3939 MORPHOLOGY AND DEVELOPMENT OF CERVICAL ATYPIA IN 106 CASES OUT OF 12,300 PREGNANCIES. (Fr.) Brux, J. de (Inst. Path. Cytol., Paris, France), C. Panopoulous and F. Coupez. *Rev Franc Gynec* 66(11-12):671-679, 1971.

Case reports of 12,300 pregnant women who received regular check-ups during pregnancy were screened and 180 cases (1.5%) of epithelial atypical of the cervix were found for a 10-yr period. Of these, 106 had received regular and thorough cytological and histological examinations, with adequate follow-up. These 106 lesions were scored objectively, as follows: 71 benign lesions and 34 borderline lesions, including 12 severe dyskaryoses and 22 lesions resembling intraepithelial carcinoma. Of the 34 severe lesions, 20 (58%) improved, 9 (27%) remained unchanged and 5 (15%) became worse. The risk of severe lesions was greater for multiparous women and those between the ages of 30-34 yrs. Hormonal imbalances that occur during pregnancy are involved in the histogenesis of the lesions; no histological or cytological indices have been found to indicate how the lesions will develop.

3940 CHROMOSOMES OF CONDYLOMA ACUMINATUM, PAGET'S DISEASE, *IN SITU* CARCINOMA, INVASIVE SQUAMOUS CELL CARCINOMA AND MALIGNANT MELANOMA OF THE HUMAN VULVA. (E.) Katayama, K. P. (Johns Hopkins U. Sch. Med., Baltimore, Md.), J. D. Woodruff, H. W. Jones, Jr. and E. Preston. *Obstet Gynec* 39(3):346-356, 1972.

Punch biopsies were taken from lesions from 21 patients with malignant conditions of the vulva, including three condyloma acuminatum cases, one Paget's disease case, six carcinomas *in situ*, ten

invasive squamous cell carcinomas and one malignant melanoma of the vulva. Biopsy material was prepared for chromosome study by the direct squash method. Five of six patients with mature carcinomas had lymph node metastases, while immature carcinomas showed no metastases. In chromosome studies, 78.4% of condyloma acuminatum cell metaphases and 55% of Paget's disease metaphases were diploid. Twenty-four percent of carcinoma *in situ* cells were diploid, 22% were triploid and 54% were tetraploid or above. Eighty-nine percent of invasive squamous cell carcinoma (immature type) cells were diploid, 11% were tetraploid and none was triploid. Thirty-seven percent of invasive squamous cell carcinoma (mature type) cells were diploid, 26% were triploid and 37% were tetraploid or above. The most striking chromosome aberrations were seen in malignant melanoma metaphases; 13% of these were diploid, 74% were triploid and 13% were tetraploid or above. Structural aberrations were also more common in malignant melanoma cells; 66 reciprocal translocations were seen in these cells. Mature type squamous cell carcinoma had the next highest frequency of structural aberrations, and condyloma acuminatum had the fewest aberrations (15 translocations).

- 3941 STEMLINE EVOLUTION OF A C57BL/10 MOUSE LYMPHOMA. (E.) Barr, K. J. (Dept. Microbiol., California St. Coll., Long Beach), B. G. Sanders, A. F. Brodetsky and R. L. Teplitz. *Arch Path* 93(1):22-25, 1972.

The splenic lymphoma of C57BL/10 mice could not be transferred to adult T6T6 mice, but could be transferred to "immunologically naive" neonatal T6T6 mice. Transplanted lymphomas had two cell populations, one with 40 chromosomes (T6 normal host cells) and one with 39 chromosomes (lymphoma cells). Spleen cells from C57BL/10 lymphoma-bearing T6T6 mice grew in C57BL/10 recipients but were rejected by T6T6 mice, suggesting that tumor transfer had been effected by true transplantation of tumor cells. The C57BL/10 lymphoma was cytogenetically mixoploid initially, but after 690 days and 50 transfers a single dominant stem cell line emerged. Every metaphase examined had 39 chromosomes, and there has been no chromosomal variation since. Karotypes showed no chromosomal translocations or other rearrangements. Tumor morphology and growth rate remained similar to those of the tumor prior to stemline evolution. Intracytoplasmic A particles (but no C particles) were seen in 10% of lymphoma cells. In an attempt to determine the presence of infectious virus in lymphomas, cell-free tumor extract was injected into adult and neonatal C57BL/10 mice. No tumors developed. It is concluded that if the A particles were of viral origin, they were incomplete and not recoverable by conventional means.

- 3942 EVIDENCE FOR A CLONAL ORIGIN OF HEAD AND NECK TUMORS. (E.) Fialkow, P. J. (Kenyatta Natl. Hosp., Nairobi, Kenya), G. M. Martin,

G. Klein, P. Clifford and S. Singh. *Int J Cancer* 9(1):133-142, 1972.

Blood and tumor biopsy specimens from 28 African patients with head and neck tumors were examined for glucose-6-phosphate dehydrogenase (G-6-PD) type. Patients were heterozygous at the G-6-PD locus and accordingly normal cells from patients contained both of the two G-6-PD phenotypes, A and B. A single enzyme phenotype in tumor cells was taken as evidence for a clonal origin for the tumor. Ten of 11 tumor biopsies from anaplastic carcinoma of the nasopharynx showed both G-6-PD types. Biopsy specimens, however, were heavily contaminated with nonneoplastic cells and no conclusion as to the origin of the tumor could be drawn. The one relatively pure anaplastic carcinoma of the nasopharynx had a single enzyme phenotype. A single enzyme phenotype was found for a squamous cell carcinoma of the palate and suspected for two other such tumors. In one well-differentiated squamous cell carcinoma of the maxillary antrum, both A and B enzymes were found; nevertheless, a clonal origin for this tumor could not be ruled out. Another antral squamous cell carcinoma had a single enzyme phenotype. Single enzyme phenotypes were also found for an adenocystic palatal salivary gland carcinoma, a plasmacytoma, a neuroblastoma, a melanoma and a reticulum cell sarcoma. A benign follicular thyroid adenoma had a single enzyme phenotype, as did a benign ectopic salivary gland adenoma. Thus, findings in virtually all cases suggest a clonal origin for mature tumors.

- 3943 HYPERPLASTIC AND EARLY NEOPLASTIC CHANGES IN THE OVARIES OF MICE AFTER GENIC DELETION OF GERM CELLS. (E.) Murphy, E. D. (Jackson Lab., Bar Harbor, Me.). *J Nat Cancer Inst* 48(5):1283-1295, 1972.

Early events in the development of bilateral ovarian tubular adenomas in C57BL/6J- \bar{w}^c/\bar{w}^c female mice were observed. This strain is characterized by early development of adenomas; mice of the same genetic background, but which were not prone to adenoma development, were observed as normal controls. In controls at one day of age, the standard number of oocytes/ovary was 6,000. In ovaries of adenoma-prone mice, the standard number of oocytes/ovary at one day of age was 49, less than 1% of normal. By 13 wk of age, no oocytes were seen in ovaries of adenoma-prone mice. At one day of age, sterile ovaries in adenoma-prone mice were composed chiefly of pregranulosa cell cords. Growing follicles or corpora lutea predominated in control ovaries by three wks of age; follicular development lagged behind controls in the adenoma-prone mice. Follicles disappeared from sterile ovaries by 13 wk and corpora lutea disappeared by 17 wk. "Germinal" epithelium invaded preovarian tissue beginning at wk eight; by 13 wk of age, it had penetrated and completely permeated two sterile ovaries, which were diagnosed as tubular adenomas. By 22 wk, 19 of 20 sterile ovaries were diagnosed as complex tubular adenomas. Interstitial cells in sterile ovaries were under-

going hyperplasia by four wk of age; the cells invaded the germinal epithelium by six wk and thin-walled blood vessels by eight weeks. The rete ovarii in sterile ovaries became hyperplastic by three wk. Interstitial cells formed inside granulosa cell cords, in theca interna of atretic follicles, in degenerating corpora lutea, in rete ovarii and directly from stromal cells. Sex hormones continued to be produced in ovaries after the disappearance of follicles and the development of interstitial cell hyperplasia.

3944 PROLIFERATIVE EPITHELIAL LESIONS OF THE URINARY BLADDER OF NONHUMAN PRIMATES INFECTED WITH *SCHISTOSOMA HAEMATOBII*. (E.) Kuntz, E. (Southwest Fdn. Res. Educ., San Antonio, Texas), W. Cheever and B. J. Myers. *J Nat Cancer Inst* 8(1):223-235, 1972.

Monkeys of eight species were infected s.c. with cercariae of the worm *Schistosoma hematobium*. When the infected monkeys died or were killed three to four months after infection, pelvic area tissues were examined. Papillary transitional cell carcinomas of the bladder were seen in a talapoin monkey which died 21 months after infection and in a capuchin monkey killed 56 wk after infection. Areas of epithelial proliferation were generally adjacent to schistosome eggs in bladder lamina propria. Two squirrel monkeys showed proliferation and squamous metaplasia of bladder epithelium, again located near *S. hematobium* eggs. An infected baboon killed one yr after infection had a papilloma in its ureter. The affected ureter contained schistosome eggs. Since spontaneous bladder cancer has not been reported in monkeys, it is thought that these lesions were caused by *S. hematobium* infection.

45 TISSUE INTERACTIONS IN MORPHOGENESIS, MORPHOSTASIS AND CARCINOGENESIS. (E.) Pirin, D. (Sch. Med., U. Leeds, England). *J Theor Biol* 34(1):61-72, 1972.

Studies of the relationship between different tissues and organs undergoing carcinogenesis and other pathological conditions are summarized. These studies provide support for the hypothesis that derangement of tissue interactions responsible for producing and maintaining biological structure is one of the fundamental mechanisms of carcinogenesis. Ultrastructural studies of skin and mammary carcinomas have revealed a series of marked changes at the junction between epithelium and connective tissue and have demonstrated that neoplastic epithelium mounts an enzyme attack on the underlying connective tissue. Based on the observation that viruses, chemicals and hormones cause remarkably similar morphological changes, different carcinogenic agents disturb the biological processes. At present it is not known if derangement of the interactions between epithelium and connective tissue arises from failure of epithelial function, failure of connec-

tive tissue function, or both, or from some impedance in communication between the tissues. Connective tissue tumors, benign and malignant tumors, and metastasis are also discussed in the context of the hypothesis of derangement of tissue interactions.

3946 GROWTH OF PRIMARY PLASMACYTOMAS IN THE MINERAL OIL-CONDITIONED PERITONEAL ENVIRONMENT. (E.) Potter, M. (Natl. Cancer Inst., Bethesda, Md.), J. G. Pumphrey and J. L. Walters. *J Nat Cancer Inst* 49(1):305-308, 1972.

Ascites cells from 15 primary mineral oil-induced BALB/c mouse plasmacytomas were injected i.p. into normal BALB/c mice or into BALB/c mice pretreated with one or two monthly i.p. injections of mineral oil. All the tumors grew in mineral oil-conditioned mice, while only three grew in unconditioned animals. Immunoelectrophoretic analysis of tumor and host cell proteins indicated that the tumors originated from host tissues. The effect of the number of conditioning doses of mineral oil on subsequent tumor development could not be properly evaluated.

3947 SPONTANEOUS STEM CELL LEUKEMIA IN YOUNG SPRAGUE-DAWLEY RATS. (E.) Richter, C. B. (Biol. Div., Oak Ridge Natl. Lab., Tenn.), P. C. Estes and R. W. Tennant. *Lab Invest* 26(4):419-428, 1972.

Over a one and one-half yr period, a total of 12 spontaneous leukemias (ten acute stem cell, one acute granulocytic, and one histologically untyped) was observed in a population of 600 outbred CR:CD (SD) rats. These tumors were studied by light and electron microscopy. The tumors characteristically appeared in young rats, and a high incidence of paralysis occurred due to encroachment of the tumor masses on the spinal cord. Hepatosplenomegaly and anemia were common findings at autopsy. Peroxidase stains of peripheral blood smears and liver imprints were negative. Although the liver and spleen were involved, infiltration of leukemic cells was most extensive in bone marrow. Liver infiltration tended to be diffuse and foci of extramedullary hematopoiesis were observed in most rats. Lymph node involvement was only secondary with the mesenteric nodes being the most common site. Thymic involvement was never observed. The pattern of neoplastic involvement in rats receiving tumor transplants differed from that in the spontaneous cases. I.p. inoculation produced large spleen and liver infiltrations. Unlike spontaneous cases, the lungs and lymph nodes were frequently involved while bone marrow involvement was less common. S.c. inoculation produced solid tumors which did not differ histologically from the leukemic form. The spontaneous leukemias were readily transplantable into CD:CR (SD) outbred and R344 inbred rats younger, but not older, than 25 days. Inoculation of rats with cell-free leukemia material failed to induce tumor formation.

Mouse leukemia virus antigens could not be detected in leukemic tissues by complement fixation nor were virus particles seen in tumor sections by electron microscopy. The characteristics of these spontaneous tumors suggest that they may serve as a useful model for the study of childhood leukemias.

- 3948 HISTOGENESIS OF ALVEOLAR SOFT PART SARCOMA. (E.) Welsh, R. A. (Louisiana State U. Sch. Med., New Orleans), D. M. Bray III, F. H. Shipkey and A. T. Meyer. *Cancer* 29(1):191-204, 1972.

Six alveolar soft part sarcomas, two granular cells myoblastomas, one carotid body tumor, and one normal carotid body were compared at the ultrastructural level. Strong similarities were noted between the alveolar soft part sarcoma and paragangliomas of carotid-body type. Similarities were the basic structural unit composed of chief cells, peripheral spindle cells, boundary laminae and surrounding vascular spaces arranged in a consistent pattern. Secretory-like granules resembling those of the carotid body were found in the chief cells of alveolar soft part sarcomas. Other similarities were the presence of light and dark cells, randomly located desmosomes between chief cells and characteristic hemidesmosomes at the periphery of chief cells. There was no similarity to the granular cell myoblastoma. The close homology between alveolar soft part sarcoma and the paragangliomas of carotid body type suggests that the tumors are of a related histogenesis.

- 3949 CHRONIC GASTRITIS AND STOMACH CANCER. (It.) Camarri, E. (Civil Hosp. Grosseto, Italy), L. Zaccherotti and E. Fanteria. *Rec Prog Med (Roma)* 51(2):144-158, 1971.

Morphologic changes induced in the mucous membrane by chronic atrophic gastritis (CAG); the relationship between pernicious anemia, achlorhydria and stomach cancer; and recent discoveries bearing on the development of CAG are reviewed. Of 150 CAG patients under treatment and observation at the Medical Clinic of Siena from 1961 to 1967, 48 died; five died from malignant neoplasms of the stomach. Of these, two had manifested clinical symptoms of cancer upon admission and both died within a year. The remaining three (2% of the total) died after two, five, and six years; biopsy confirmed CAG. Abnormalities in the mucous membrane including metaplastic changes (intestinal pseudometaplasia) occur frequently in CAG, but such changes occur also in a substantial number of cases of gastritis with a nonmalignant course. The finding that stomach cancer develops in the area of the glandular collum, where cells take part in regenerative processes of the mucous membrane, may show a causal relationship between CAG and stomach cancer. The same applies to hyperplastic structures in the

mucous membrane which can lead to cancer by an intermediate stage of adenomatous polyps which frequently become malignant. The high incidence of gastric cancer among pernicious anemia patients is attributed to the histological alterations (hyperplasia, atrophy, adenomatous polyps) of the gastric mucosa occurring in the course of this hemopathy. Histamine-resistant achlorhydria is a functional condition, frequent in both CAG and gastric cancer patients. But gastric cancer is often accompanied by normal hydrochloric acid secretion as well. Available evidence does not seem to substantiate the claim that CAG is a precancerous state. However, it precedes development of malignant gastric neoplasia in a certain number of cases. Gastric cancer can develop for unknown reasons at any age, no matter whether the mucosa secretes hydrochloric acid normally or abnormally.

- 3950 ULTRASTRUCTURAL SITE OF ATPase ACTIVITY IN THE MOUSE HEPATOMA CELL CYTOPLASMIC MEMBRANES. (Rus.) Petrunyaka, V. V. (Inst. Exp. Clin. Oncol., Moscow, USSR), N. T. Raikhlin, N. A. Filippova and L. V. Ol'shevskaya. *Vop Onkol* 17(12):57-63, 1971.

The effect of cell differentiation on ATPase activity in the cytoplasmic membrane was studied in Gel'shtein's minimal mouse hepatoma 46 and anaplastic hepatoma 22^a; normal liver cells in C3HA mice were used as controls. A modification of Wachstein and Meizel's method was used to determine ATPase. In normal liver tissue fixed with 5% glutaraldehyde maximum ATPase activity was found in microvilli of the bile capillaries, while little activity was present in microvilli of Disse's spaces, and no activity was observed in smooth parts of the membrane. When fixed with 2.5% glutaraldehyde, however, a marked increase occurred in ATPase in the microvilli of Disse's spaces and the activity in smooth parts of the membrane was as great as that in microvilli of the bile capillaries. This difference in results is attributed to the almost complete inhibition of Na⁺-K⁺-ATPase by 5% glutaraldehyde. However, hepatomas were fixed only with 5% glutaraldehyde and were therefore compared with normal liver fixed in 5% glutaraldehyde. In hepatoma 46, ATPase activity was highest in the microvilli of the bile canaliculi and smooth parts of the membrane and was low in Disse's spaces. This is apparently because of Mg⁺⁺-dependent ATPase activity which was not observed in normal liver tissue. In most cells of hepatoma 22^a there was no ATPase activity at all or the activity was spread over all parts of the membrane, while in a small number of cells the ATPase activity was high along the entire perimeter. There was no correlation between the extent of structural dedifferentiation and the site of ATPase activity; ATPase activity could occur at any site in the cytoplasmic membrane with equal probability. It is concluded that as hepatoma cells undergo dedifferentiation, ATPase activity becomes increasingly less associated with specific sites in the cytoplasmic membrane.

- 3965 A MORPHOMETRIC ANALYSIS OF HUMAN BREAST CARCINOMA. (E.) Underwood, J. C. E. (Dept. Path., Sheffield U., England). *Brit J Cancer* 26(3):234-237, 1972.

A morphometric procedure was devised to determine the volumetric cellular composition of human breast carcinoma. Ten surgical specimens of scirrhous carcinomas and two of medullary carcinoma of the breast were selected. An equatorial slice passing close to the center of the tumor was fixed and blocks of tumor were sliced, stained with hematoxylin and eosin, and the percentage volume of tumor cells was estimated morphometrically by point counting. The mean tumor cell volume of the scirrhous carcinomas was 287.6 mm^3 (range $10.5-845 \text{ mm}^3$), or 21.5% (range 3.9 to 39.4%) of the total volume of the neoplasm. The medullary lesions had a mean tumor cell volume of 417 mm^3 (range 342 to 492 mm^3), 64.5% (range 54.3 to 76.4%) of the total volume of the neoplasm. The main errors in volumetric analysis of tissues by morphometry were fixation-induced shrinkage and human error in identification of tumor cells. The wide range of total cell volume of scirrhous neoplasms was not entirely related to the size of the neoplasm; therefore, conclusions on the cellularity of breast tumors based solely on the size of the tumor are inadvisable.

- 3966 MALE MAMMARY CANCER: AN ANALYSIS OF 32 CASES. (E.) Crichlow, R. W. (Sch. Med., U. Pennsylvania, Philadelphia), E. L. Kaplan and W. H. Kearney. *Ann Surg* 175(4):489-494, 1972.

Thirty-two cases of male mammary cancer seen over a 25-year period (1940-1964) are described. Five of the 32 patients were Negroes; the rest were Caucasian. Sixteen tumors appeared in the right breast and 15 in the left breast. None of the patients had received hormone therapy prior to diagnosis of mammary cancer. The ages of patients ranged from 36-82 yr (mean = 60 yr). Twenty tumors appeared to be invasive ductal carcinoma; the degree of anaplasia varied from tumor to tumor and from one part of a tumor to another part. There were two Paget's carcinomas of the breast. Of 24 patients subjected to radical mastectomy, eight had axillary lymph node metastases. The survival rates at five and ten yr after diagnosis were 47% and 38%, resp. Although comparison between the sexes of prognosis in mammary cancer is hindered by the scarcity of data for men, the available data do suggest a poorer prognosis for men overall.

- 3967 CANCER MORTALITY: VITAL STATISTICS VERSUS CANCER REGISTRY. (E.) Steinitz, R. (Ministry Hlth., Jerusalem, Israel) and C. Costin. *Israel J Med Sci* 7(12):1405-1412, 1971.

Cancer mortality figures compiled by two Israeli agencies, the Central Bureau of Statistics (CBS) and the Israel Cancer Registry (ICR), for the years 1964 and 1965, were compared. Differences were expected between ICR and CBS figures since the

CBS cancer mortality figures were based on underlying cause of death only, while the ICR figures were based on the mortality of the population with cancer. The sum of cases reported as primary or unspecified liver cancer in the ICR tables was greater than the number reported by the CBS. Similar findings applied to uterine carcinoma. ICR data showed that the ratio of uterine cervix to uterine corpus cancer was 3:4. The CBS figures indicated a greater preponderance of corpus carcinoma. Cancer mortality as reflected by the ICR was generally higher than that reflected by the CBS. Some obstacles to the accumulation of complete and accurate cancer mortality data are discussed.

- 3968 IRRADIATION IN THE EPIDEMIOLOGY OF LEUKEMIA AMONG ADULTS. (E.) Gibson, R. (St. U. New York, Buffalo), S. Graham, A. Lilienfeld, L. Schuman, J. E. Dowd and M. L. Levin. *J Nat Cancer Inst* 48(2):301-311, 1972.

The association of diagnostic X-irradiation and increased leukemia risk was studied in a survey of 1,414 adults who had died of leukemia or who suffered from diagnosed leukemia. The cases were from 26 upstate New York counties and the Baltimore and Minneapolis-St. Paul areas. There were 1,370 controls. In all cases details of X-ray exposure by site and numbers of films were taken from hospital records. Increased risks associated with irradiation were found only for acute myeloid and monocytic leukemia. Males with 41 or more X-ray films to all sites and especially to the "trunk" (i.e., thorax, abdomen and pelvic area) showed greater risks of leukemia compared to patients with fewer exposures. The risks for more and less exposed patients were 5.06 and 2.34, resp. No correlation of myeloid leukemia risk and radiation was found for females. As the numbers of X-ray films in males increased the relative risk of myeloid leukemia increased also. Neither irradiated males nor females had increased risks for any other leukemia type. The results indicated that, while small, the proportion of leukemia cases attributable to diagnostic irradiation is important. Still, most patients given irradiation do not develop leukemia.

- 3969 CANCER MORTALITY AND IMMIGRATION TO ISRAEL, 1950-67. (E.) Halevi, H. S. (Tel Aviv U. Med. Sch., Israel), F. Dreyfuss, E. Peritz and U. O. Schmelz. *Israel J Med Sci* 7(12):1386-1404, 1971.

Figures on cancer mortality among Israelis are presented; the data were compiled by the Israeli Central Bureau of Statistics and cover the period 1950-1967. For both sexes and for all sites, the lowest mortality rates were seen among Israelis born in Asia and Africa. The age of onset of stomach and prostate carcinoma and of leukemia was greater in Israelis born in Israel than among those born elsewhere. Mortality rates for lung neoplasms and intestinal neoplasms except rectal neoplasms increased throughout the data period. Mortality from stomach tumors and from rectal cancers in males declined during the data

period. A steep decrease in mortality rates was seen for rectal cancer among men and women born in Asia and Africa. Mortality curves for carcinoma of most sites did not show any clear and well-defined trend. Overall cancer mortality increased markedly among Israelis born in Iraq as compared to mortality among Israelis born in Yemen, among whom overall cancer mortality decreased slightly. Leukemia mortality was much higher among European and American-born Israelis over 25 yr than among those born in Asia and Africa.

- 3970 CANCER IN JEWISH IMMIGRANTS. (E.)
Steinitz, R. (Ministry Hlth., Jerusalem, Israel) and C. Costin. *Israel J Med Sci* 7(12):1413-1436, 1971.

Data on cancer morbidity from the Israeli Central Bureau of Statistics were analyzed and five-yr age-specific incidence rates for cancers of various sites among Israelis were established. A total of 31,194 newly diagnosed cancer cases were covered by the data, which dealt with the period 1960-1966. Extremely high rates for many cancers were found for Israeli Jews from Eastern and Central Europe, while extremely low rates were seen among Yemeni and Iranian Jews. The latter groups, however, had high rates of esophageal cancer. High rates for stomach cancer were seen among Israelis from all nations except Yemen and Iraq. Stomach cancer was most prevalent among Jews from Eastern Europe. Lung cancer had its highest incidence among Jewish male Israelis from Greece, Bulgaria and Turkey. Yemeni Israelis had low lung cancer rates. Yemenites were also conspicuous for their low morbidity from mammary carcinoma. Israeli Jews from northwest Africa had high rates for cervical cancer. The Israeli population generally appeared to have a high rate for leukemia and lymphoma.

- 3971 MENOPAUSE AND BREAST CANCER RISK. (E.)
Trichopoulos, D. (Harvard Sch. Public Hlth., Boston, Mass.), B. MacMahon and P. Cole. *J Nat Cancer Inst* 48(3):605-613, 1972.

Age at menopause and type of menopause from hospital records of breast cancer patients were compared with similar information reported by a national probability sample of women. The cancer series consisted of 3,887 patients selected from those reported to the Connecticut Cancer Registry between 1950-1959. The national sample comprised 3,581 women responding to the National Health Examination Survey of 1960-1962. The validity of the comparison and the effect of the relatively large number of breast cancer patients whose menopause histories were deficient were evaluated; no substantial bias was identified. Overall, surgically induced menopause was associated with a reduction in breast cancer risk to about 60% of that experienced by women having natural menopause at ages 45-54. The decrease was greatest for those with menopause induced before age 45, but induction up to age 50 was protective. Among

women with menopause induced before age 35, breast cancer risk remained as low as one-third that expected 30 and more years later. Relative risk of breast cancer increased with age at natural menopause. Women with natural menopause at age 55 or older had twice the risk experienced by those whose menopause occurred before age 45. The relative risk of breast cancer associated with late natural menopause was greatest after age 70. These findings illustrate the long period which may elapse between etiologic events and the appearance of human cancer; and they imply that the ovarian etiology of human breast cancer is not restricted to cancers appearing during the years of active ovarian function.

- 3972 MALIGNANT TROPHOBLASTIC DISORDERS. EPIDEMIOLOGIC ASPECTS AND RELATIONSHIP TO HYDATIDIFORM MOLE. (E.) Matalon, M. (Tel Hashomer Government Hosp., Israel), B. Paz, M. Modan and B. Modan. *Am J Obst Gynecol* 112(1):101-106, 1972.

Records of all women with newly diagnosed choriocarcinoma and chorionadenoma destruens in Israel between 1950-1965 were reviewed. The mean annual incidence of malignant trophoblastic disorders (MTD) was 1:15,000 live births in Jewish women. Incidence was similar in all age groups below 40 yr, with a sharp rise subsequently; this is in contrast to Puerto Rico where an increased incidence in the under-20 age group was observed as well. Birth rank had no effect on MTD incidence, and the only difference among ethnic groups was a higher incidence in European-born women above age 45. In women with a history of hydatidiform mole, the risk of developing MTD declined from 21.8% in 1950-1954 to 4.4% in 1960-1965. The decline is attributed to earlier recognition and better treatment of hydatidiform mole.

- 3973 CARCINOMA OF THE CERVIX IN JEWISH WOMEN IN ISRAEL, 1960-67: AN EPIDEMIOLOGICAL STUDY. (E.) Pridan, H. (Dept. Social Med., Hadassah U. Hosp., Jerusalem, Israel) and A. M. Lilienfeld. *Israel J Med Sci* 7(12):1465-1470, 1971.

The life habits of Israeli Jewish women with carcinoma of the cervix (index group) were compared with those of a matched group of Jewish women suffering from a non-malignant gynecological condition and with those of a matched group from the general population. Of a total of 452 cases of cervical carcinoma reported to the Cancer Registry from 1960 to 1967, 222 were included in the index group. No differences were seen between the index group and the control groups in geographic origin, population of birthplace, average number of cities lived in, education, degree of orthodoxy of religion, number of pregnancies, number of abortions, median age of menarche, frequency of intercourse, total period of sexual relations, or social class. Index women, however, tended to immigrate to Israel later than did the women in the control groups. Index cases also

commenced sexual relations earlier and had more sexual partners than women in the control groups. More index women had been widowed or divorced. Although the incidence of herpes type 2 infections was higher in index women (38.4%) than in the general population controls (12.8%), the incidence in the gynecological controls was the highest (51.5%). The husbands of women in the index group tended to have had a greater number of sexual partners than had the husbands of women in either control group. This finding seems to strengthen the possibility of the operation of an infective agent in the etiology of carcinoma of the cervix uteri.

- 3974 HIGH INCIDENCE OF GASTRIC CARCINOMA IN A COAL MINING REGION. (E.) Matolo, N. M. (U. Utah Coll. Med., Salt Lake City), M. R. Klauber, W. M. Gorishek and J. A. Dixon. *Cancer* 29(3):733-737, 1972.

An epidemiologic study was conducted from January 1965 to December 1969 to determine the incidence of gastric cancer in Carbon and Emery Counties, Utah, the only coal-mining regions in the state. Fifty-nine percent of male patients in the two counties were coal miners. The age-adjusted gastric cancer incidence in the miners was at least three times that of nonminers and at least eight times that of males in counties with no coal mining. The increased risk for females in Carbon and Emery Counties was not statistically significant, but the increased risk in males was highly significant compared to other Utah males. All homes of gastric cancer patients in Carbon and Emery Counties were heated with coal, and in some of the homes coal was used for cooking. It is concluded that coal mining in the area and, to a lesser degree, the extensive use of soft coal might be etiologic factors. If coal smoke particles reach the stomach, gastric carcinoma could be induced by benzo(a)pyrene and its related carcinogens.

- 3975 RELATION BETWEEN CANCER AND CONGENITAL MALFORMATIONS. THE VALUE OF SMALL SERIES, WITH A NOTE ON PINEAL TUMORS IN NATIVE AND MIGRANT JAPANESE. (E.) Miller, R. W. (Nat'l. Cancer Inst., Bethesda, Md.). *Israel J Med Sci* 7(12):1461-1464, 1971.

Definitive evidence of a relationship between specific cancers and congenital malformations usually requires study of hundreds of cases of a particular cancer or dozens of a rare anomaly with very high risk of cancer. Associations between Down's syndrome and leukemia, congenital hemihypertrophy or congenital aniridia and Wilm's tumor, and between Bloom's syndrome and acute myelogenous leukemia or squamous cell carcinoma of the tongue were discovered using this approach. However, when the population of an area is small, there may be difficulties in obtaining large enough numbers of cases for epidemiologic study. A useful method in these cases is to find

two or three patients or families with a previously unsuspected association involving a congenital malformation and cancer and to test this association elsewhere epidemiologically. For example, Good and his colleagues developed their concept of immunosurveillance from laboratory observations and human data on eight cases of ataxia-telangiectasia with lymphoma, three of Wiskott-Aldrich syndrome with lymphoreticular neoplasia and three of X-linked agammaglobulinemia with acute lymphocytic leukemia. Sophisticated laboratory procedures are also being used to explore the connection between oncogenesis and teratogenesis as they occur together in certain persons or families. In this manner, an association between Fanconi's anemia and the enhanced transformability of the patients' cultured skin fibroblasts by SV40 was discovered. It is also possible, even in small populations, to demonstrate rare associations in a subpopulation. In a recent study, the high incidence of pineal tumors in Japanese migrants to Hawaii was discovered. This finding substantiated the previously published claim of a high incidence of pineal tumors in native Japanese.

- 3985 MECHANISMS OF METASTASIS: AN ULTRASTRUCTURAL STUDY ON THE RELATIONSHIP BETWEEN VASCULATURE AND NEOPLASTIC CELLS ORIGINATING IN THE MASTOMYS STOMACH. (E.) Tazawa, K. (Niigata U. Sch. Med., Japan). *Acta Medica Biol* 18(4):219-248, 1971.

To determine the relationship of migrating neoplastic cells to the endothelium and the basement membrane of the vascular system, ultrastructural studies were performed on 27 histologically proven malignant epithelial neoplasms developing spontaneously in the glandular stomachs of 21 mastomys aged 14-30 months and weighing 45-90 g. Changes similar to those observed in inflamed vessels were found in the small vasculatures in the neoplastic tissue. The basement membrane on the side of the vascular vessels was often well-preserved, but occasionally showed focal disruption at the points of the "hooking" of neoplastic projections. Resistance of the membrane to invading neoplastic cells was unexpectedly high. In areas of erythrocytic extravasation, free endothelial cells were sometimes attached to the invading neoplastic cells. It is postulated that differences in the biologic features of two types of neoplastic cells, the solid form and the free ascitic form without preserved basement membrane, may be important factors in vascular invasion by neoplastic cells.

- 3986 HYDROLASE ACTIVITY FOR N-SUBSTITUTED AMINOACYL-tRNA IN RIBOSOMES AND SUPERNATANT FRACTIONS FROM HUMAN TISSUES AND TUMORS. (Ger.) Neth, R. (U. Pediat. Clin. Polyclin., Hamburg, West Germany), N. Dunlop, G. Heller-Schöch, G. Schöch, and K. Winkler. *Hoppe Seylers Z Physiol Chem* 353:117-121, 1972.

Activities and characteristics of hydrolase activity are described for N-substituted aminoacyl-tRNA (aa-tRNA) in ribosomes and supernatant fractions of human tonsils, spleens, tumors, normal and leukemic leukocytes, and rat tissue and rat tumors. The "non-specific fragmentation reaction without puromycin" in observed ribosomes from spleen and tumors may be due to contamination with foreign proteins, which have a high hydrolase activity for N-substituted aa-tRNA. High hydrolase activity was found in the supernatant fractions of human spleen, leukocytes, adenocarcinomas, and paramyeloblasts as well as in rat spleen, kidneys and lungs, upon centrifugation at 100,000 x g. In these supernates, there are extreme differences in hydrolase activities. The reason is the varied tRNA content of these organs, the hydrolase being inhibited by unloaded tRNA. The function of this enzyme is probably the hydrolysis of peptidyl-tRNA, inadvertently released from a peptide chain. The difference in hydrolase activity between paramyeloblasts and paraproerythroblasts is of particular interest in the biochemical supplement to the cytochemical studies in leukemia.

- 3987 NUCLEIC ACID CONTENT IN CELL NUCLEI OF THE HUMAN LIVER AND SPLEEN IN VARIOUS FORMS OF LEUKEMIA. (Rus.) Drel', K. A. (Donetsk Med. Inst., Donetsk, USSR) and S. A. Veksler. *Vop Med Khim* 17(6):632-634, 1971.

Nucleic acid levels in cell nuclei of the livers and spleens of 42 patients who died of leukemia and 19 healthy people who died accidentally were determined spectrophotometrically. In nuclei of liver cells the RNA level decreased 20-30% in hemocytoblastosis, myelogenous leukemia, and lymphocytic leukemia but increased 17% in reticulum cell sarcoma. DNA levels in liver nuclei decreased greatly in leukemia (66% in hemocytoblastosis, 35% in myelogenous leukemia and 40% in lymphocytic leukemia), but decreased slightly in reticulum cell sarcoma. Nucleic acids in spleen cell nuclei decreased in both forms of leukemia (52% in reticulum cell sarcoma and 50% in lymphocytic leukemia). RNA decreased 48% in lymphocytic leukemia and 38% in reticulum cell sarcoma. Morphologically, hyperplastic cell growth and lymphocytic leukemic infiltrates were observed in both organs. The decreases in RNA and DNA are due to cell proliferation and hyperplasia in leukemia. In addition to cells undergoing mitosis, there is a large number of long-living cells which are unable to differentiate and mature, divide, and synthesize DNA.

- 3988 PROTEIN METHYLASES IN HEPATOMAS. (E.) Paik, W. K. (Temple U. Sch. Med., Philadelphia, Pa.), H. W. Lee and H. P. Morris. *Cancer Res* 32(1):37-40, 1972.

Levels of various protein:S-adenosyl-L-methionine methyltransferases were examined in solid hepatomas with various growth rates. Protein methylase I (protein-arginine:S-adenosyl-L-methionine methyltransferase) activity in tumors roughly paralleled tumor growth rate. The enzyme activity in the host

liver was significantly elevated in animals bearing both a slow-growing and a fast-growing hepatoma but otherwise remained in the normal range. Protein methylase II (protein-carboxyl:S-adenosyl-L-methionine methyltransferase) activity in both tumors and host livers showed no significant change from normal rat liver. Protein methylase III (protein-lysine:S-adenosyl-L-methionine methyltransferase) decreased with decreasing rate of growth of tumors; in a fast-growing Novikoff hepatoma, it was approximately two to three times higher than that of normal rat liver. The activity in host livers was essentially the same as for the normal rat liver. These results suggest that methylation of the guanidino group of arginine, which is particularly abundant in histone, might have some important specific role in neoplastic growth.

- 3989 HISTOENZYMATIC CHARACTERISTICS OF HUMAN LARYNGEAL CANCER. (Rus.) Avtandilov, G. G. (Inst. Human Morphol., Moscow, USSR), I. S.

Kruglova and L. I. Avtandilova. *Vop Onkol* 18(3): 28-31, 1972.

A comparative microspectrophotometric study was made of enzymatic activity of slices from squamous-cell carcinomas of the larynx and quantitative changes in the oxidative enzymes in the neoplasms after radiation therapy. Larynxes, either partially or completely resected, from 14 male patients over 45 yr old were studied. Five of them received radiation therapy (6000-10000 r) preoperatively. Glutamate dehydrogenase and cytoplasmic α -glycerophosphate dehydrogenase were determined by a modified version of the Rubinstein-Klatzo-Miquel method; mitochondrial α -glycerophosphate dehydrogenase and succinate dehydrogenase were determined by the method of Nachlas *et al.* The activity of glutamate dehydrogenase varied in different layers of the squamous cell epithelium of intact sections of the mucous membrane, being highest in the cytoplasm of cells in the growth layer and lowest in the prickle-cell layer. The activities of glutamate dehydrogenase and succinate dehydrogenase in parts of the tumor where growth was submerged were three times higher and the cytoplasmic α -glycerophosphate dehydrogenase was four times higher than in the multilayered squamous epithelium of the laryngeal mucosa. These findings indicate that the rate of lipid metabolism is increased in the multilayered squamous-cell epithelium of the larynx in patients with laryngeal cancer. In cells of the growing tumor the rate of protein synthesis is increased, as are carbohydrates taking part in α -glycerophosphate synthesis. Mitochondrial α -glycerophosphate dehydrogenase was decreased by 15%. There was a sharp decrease in the activities of glutamate-succinate dehydrogenase and cytoplasmic α -glycerophosphate dehydrogenase in the cylindrical cells of the epithelium after radiation.

3990 COLLAGENOLYTIC ENZYMES IN HUMAN NEOPLASMS.
(E.) Dresden, M. H. (Baylor Coll. Med., Houston, Texas), S. A. Heilman and J. D. Schmidt. *Cancer Res* 32(5):993-996, 1972.

A variety of human tissue specimens were examined for their ability to produce collagenolytic enzymes in culture. Basal and squamous cell carcinomas, keratocanthomas, and carcinomas of the colon demonstrated a very high frequency of collagenolytic activity. Nonmalignant skin lesions, i.e., actinic and seborrheic keratoses, normal skin, and neoplasms of mesenchymal origin only rarely produced collagenase. Basal cell, squamous cell, colon, and endometrial carcinoma enzymes were isolated and purified. The tumor collagenases degraded soluble native collagen into tropocollagen fragments (75% TC_A and 25% TC_B), showed maximum activity at neutral to alkaline pH, and were inhibited by EDTA, cysteine, and pooled human sera. These results indicate that collagenolytic enzymes from human neoplasms and normal human skin are similar.

3991 PTERIDINE AND RIBOFLAVIN IN TUMOR TISSUE AND THE EFFECT OF CHLORAMPHENICOL AND

ISOXANTHOPTERIN. (E.) Kokolis, N. (Dept. Gen. Biol., U. Athens, Greece), N. Mylonas and I. Ziegler. *Z Naturforsch* 27(3):292-295, 1972.

The results of injection experiments to determine the effects of chloramphenicol and isoxanthopterin on tumor growth and on tetrahydrobiopterin/isoxanthopterin (TH/IX) and tetrahydrobiopterin/riboflavin (TH/RB) ratios in human skin tumors and mouse submaxillary glands are reported. Male and female Wistar rats weighing between 200-250 g were injected s.c. with 80×10^6 T-8 Guerin human cancer cells. Isoxanthopterin injections at 3 μ g/g body wt were made i.p. every 12 hr for ten days; chloramphenicol at 200 μ g/g body wt was injected i.p. every six hr for ten days. Rats receiving both drugs showed delayed tumor growth and longer survival times than untreated rats. The delay in tumor growth and the increase in life time were the most marked after isoxanthopterin injection. The submaxillary glands contained 0.760 μ g riboflavin and 0.330 μ g TH; the human skin tumors contained 1.490-2.530 μ g TH and 0.270-0.330 μ g riboflavin. TH was also found accumulated in the transplanted growing tumors. Isoxanthopterin was not present in human tumor tissue or submaxillary glands. Decreased xanthinoxidase activity is presumably involved in the high TH/IX and/or TH/RB ratios characteristic of tumor tissue and regeneration blastema. Thus the regulation of this enzyme could be an important factor in neoplastic growth.

3992 THE RELATIONSHIP BETWEEN SYNTHESIS AND METHYLATION OF DNA IN MOUSE FIBROBLASTS.
(E.) Adams, R. L. P. (Dept. Biochem., U. Glasgow, Scotland). *Biochim Biophys Acta* 254(2):205-212, 1971.

Studies on the *in vivo* methylation of DNA in cultured mouse L cells confirm the presence of a distinct lag between synthesis of DNA and its methylation. To determine the lag period, mouse L cells subcultured from the stationary phase were synchronized by treatment with aminopterin for 16 hr. This treatment extends the growth period before DNA synthesis starts. The block in DNA synthesis induced by aminopterin was reversed by thymidine; the DNA made at different points in the synthesis (S) phase was then investigated by incubating the synchronized cells with 5-bromodeoxyuridine. The DNA made in the first hr of S was more extensively methylated than that made later in the S phase. Moreover, methylation of this early DNA was completed very soon after synthesis. This was in contrast to the DNA made between two and three hr of S phase and particularly to the DNA made between four and five hr of S phase. The significance of these observations is unclear. The function of methyl groups in 5-methylcytosine in DNA is unknown, but the evidence does not support a role for DNA methylation in the determination of which genes are to be transcribed.

3993 STUDY OF THE PRODUCTION OF ALPHA-1-FETO-PROTEIN (FP) DURING THE DEVELOPMENT OF

PRIMARY CANCER OF THE LIVER: 83 CASES. (Fr.) Sankalé, M. (Med. Fac., Dakar, Senegal), R. Masseyeff, P. Teyssier and L. Leblanc. *Arch Franc Mal Appar Dig* 60(12):615-628, 1971.

Both qualitative and semi-quantitative determinations of α_1 -fetoprotein (α_1 -FP) were made on 83 African patients (64 men and 19 women). Liver cancer was confirmed, either by autopsy or biopsy, in 47 of these 83 patients. Clinical forms of liver cancer diagnosed were hepatomegaly (56 cases), cirrhotic (14 cases), pseudosuppurative (4 cases), and protracted in which the patient survived for more than six months (9 cases). Associated diseases included polyarthritis (1/83), polycythemia (2/83), hypoglycemia (6/83), and hypercholesterolemia (11/83). Histological examinations, made on 27 patients, showed that 15 had trabecular hepatocellular cancer, one had mixed trabecular and vesicular hepatocellular cancer, nine had unidentified hepatocellular cancer, one had anaplastic cancer, and one had mixed cholangiocellular and hepatocellular cancer. No correlations were found between the presence or titer of α_1 -FP and the sex, age, geographic origin, ethnic origin, clinical form, or histological class of cancer. Of the 11 patients with hypercholesterolemia, eight produced α_1 -FP (72.7%). However, there were not enough patients in this group to draw any definite conclusions. Determinations of α_1 -FP were made at least three times on 30 patients with liver cancer. In 10/11 patients with negative findings, no change occurred during the course of the disease. In the 19 patients who secreted α_1 -FP, little or no change occurred in the level of this protein during the course of the disease.

3994 LIVER BIOPSY IN HODGKIN'S DISEASE. CLINICOPATHOLOGIC CORRELATIONS IN 127 PATIENTS. (E.) Bagley, C. M., Jr. (Nat'l. Cancer Inst., Bethesda, Md.), J. A. Roth, L. B. Thomas and V. T. Devita, Jr. *Ann Intern Med* 76(2):219-225, 1972.

Liver biopsy sections in 127 patients (89 previously untreated) with Hodgkin's Disease (HD) were classified for the presence of Reed-Sternberg cells and other cellular infiltrates and abnormalities. The histologic findings were then correlated with clinical and laboratory findings in each patient. In the 20 patients with positive biopsies (eight untreated and 12 previously untreated), atypical reticulum cells were seen in association with Reed-Sternberg cells in the portal triads involved with HD. In the 89 previously untreated patients, there was no correlation between the absence of infiltrates or the presence of mononuclear or mixed cell infiltrates and other histologic or clinical variables, including symptoms, liver size, stage of nodal disease, liver function tests, Lukes-Butler class, eosinophil count, or prognosis. When these patients were classified by extent of nodal disease, more extensive disease showed significant correlations with fever, weight loss, liver enlargement, and mixed cellularity Lukes-Butler classification. Alkaline phosphatase and sulfobromophthalein tests were of

little value in predicting positive findings. Like mononuclear and granulocytic infiltration and hepatomegaly, alkaline phosphatase elevation and increased sulfobromophthalein retention may be nonspecific hepatic reactions to the presence of HD elsewhere in the patient. However, patients with splenomegaly had a high risk of liver involvement. The frequency of positive biopsies was approximately doubled by performing a laparotomy or peritoneoscopy when a percutaneous biopsy was negative.

3995 ENHANCEMENT BY INTERFERON OF THE SPECIFIC CYTOTOXICITY OF SENSITIZED LYMPHOCYTES. (E.) Lindahl, P. (Inst. Cancer Res., Villejuif, France), P. Leary and I. Gresser. *Proc Nat Acad Sci USA* 69(3):721-725, 1972.

The effect of interferon preparations on the cytotoxicity of sensitized lymphocytes for allogeneic target cells was examined. C57BL/6 mice were injected i.p. with 5×10^7 mouse lymphoid leukemia L 1210 cells; splenic lymphocytes were obtained from immunized or normal C57BL/6 mice. L 1210 cells, an interferon-resistant subline of L 1210 cells (L 1210-R), and Ehrlich ascites cells were the target cells. Mouse, human, and rabbit interferon preparations were tested on mouse L-, monkey BSC-, and rabbit RK13 monolayer cell cultures, resp. Splenic lymphocytes from C57BL/6 mice immunized with allogeneic L 1210 cells lysed ^{51}Cr -labeled L 1210 target cells readily within six hr of incubation. This specific cytotoxicity was markedly increased when the sensitized lymphocyte suspensions were first treated with mouse interferon preparations. Interferon was shown to act on the sensitized lymphocytes and not on the target cells; specific cytotoxicity was enhanced by all mouse interferon preparations tested. Control immune lymphocytes and interferon-treated immune lymphocytes were not cytotoxic for Ehrlich ascites target cells. Splenic lymphocytes from nonimmunized C57BL/6 mice were not cytotoxic for L 1210 target cells and prior interferon treatment did not make them cytotoxic. The results indicate that interferon enhances a specialized cellular function in addition to its inhibition of viral multiplication and inhibition of cell division.

3996 GLYCOGEN METABOLISM IN REGENERATING LIVER AND LIVER NEOPLASMS. (E.) Lea, M. A. (Coll. Med. Dent. New Jersey, Newark), P. Murphy and H. P. Morris. *Cancer Res* 32(1):61-66, 1972.

Glycogen levels in mice and rat livers were examined after partial hepatectomy to determine if an inverse correlation exists between glycogen concentration and growth rate of hepatic tissues. Maximum DNA synthesis occurred later after partial hepatectomy in mouse liver than in rat liver, and there was a similar delay in maximum glycogen depletion. The decline in activities of glycogen synthetase and phosphorylase did not parallel changes in glycogen concentration in the regenerating rat liver. The glycogen concen-

tration of two slowly growing tumors was greater than in the rapidly growing tumors examined. *In vitro* assays of tumor glycogen synthetase activity showed a decrease to less than 25% of the activity in normal or host liver. On addition of glucose 6-phosphate this change was less marked, and in the slowest growing hepatoma there was no significant difference in activity. Glycogen phosphorylase activity decreased in the hepatomas, but was stimulated by AMP; in the most rapidly growing tumor, AMP caused a doubling of the enzyme activity. Cysteine inhibited glycogen phosphorylase activity in the fast-growing tumor but increased the activity in the rat liver and the gastrocnemius muscle. Acid α -glucosidase activity was markedly increased in the fast-growing tumor though not in regenerating rat liver. It is concluded that glycogen metabolism in regenerating liver more closely resembles that in normal liver than in rapidly growing hepatomas.

3997 PYRIDINE-ADENINE DINUCLEOTIDE TRANSHYDROGENASE ACTIVITY IN CELLS CULTURED FROM RAT HEPATOMA. (E.) De Luca, C. (Sch. Dent., State U. New York, Buffalo) and R. P. Gioeli. *Canad J Biochem* 50(5):447-456, 1972.

Some characteristics of transhydrogenase (TH) activity found in *in vitro* rat hepatoma cell preparations are described. Cell line H4-II-E-C3 (H4 cells), derived from a minimal-deviation hepatoma, was used. TH activity measurement was based on the reduction of two specific analogues of NAD, the 3-acetylpyridine analogue (3AP-NAD) and the thionicotinamide analogue (TN-NAD), in the presence of reduced NAD and a cell preparation treated with digitonin. TH activity was first observed with crude H4 cell homogenates using Tris buffer at pH 8.6 and with TN-NAD as acceptor; addition of dithiothreitol (DTT) significantly increased the rate of transfer to the analogue. Digitonin treatment immediately exposed full enzyme activity. Storage half-life of TH activity in digitonin preparations was about 16-18 hr at 5°C. Both 3AP-NAD and NADH had typical Michaelis saturation curves, yielding apparent half-saturation values of 3.55×10^{-4} M and 9.87×10^{-6} M, resp. Maximum TH activity with 3AP-NAD as acceptor occurred at pH 5.8; Tris buffer caused 50-60% inhibition at pH 7.0-8.5. In the presence of DTT, a second area of optimum activity was seen between pH 8.0-9.0, thus reversing the Tris effect. Similar results were obtained with TN-NAD as acceptor. Addition of androsterone, ATP, or NAD at the start of the reaction, before addition of NADH, had an inhibitory effect in all cases. The observed stoichiometry led to the conclusion that hydrogen was transferred directly from NADH to 3AP-NAD.

3998 ACTIVITIES OF HEXOKINASE AND ASPARTATE- AND ALANINE AMINOTRANSFERASES IN TRANSPLANTED RAT SARCOMAS. (Rus.) Il'in, V. S. (S. M. Kirov Inst. Postgrad. Med., Leningrad, USSR) and P. Ya. Kovner. *Vop Med Khim* 17(6):644-649, 1971.

Activities of hexokinase and aspartate- and alanine-aminotransferases and changes in them induced by hydrocortisone were studied in three different transplanted rat sarcomas. Sarcomas M-1, 45, and Jensen sarcomas were inoculated s.c. into non-inbred white rats weighing 100-160 g. The activities of the enzymes in tumors were determined 7-9 and 15-16 days after inoculation. Hydrocortisone was administered s.c. (5 mg/100 g body weight daily for seven days), starting from the second day after inoculation. The animals were killed 24 hr after the last injection of hydrocortisone. Sarcomas M-1 developed rapidly, weighing 14.3 ± 2.5 g 7-9 days and 35.5 ± 3.68 g 14-16 days after inoculation; Jensen sarcomas developed slowly, weighing 6.71 ± 0.70 g and 22.7 ± 3.01 g, resp. The activity of hexokinase was highest in sarcoma M-1, being 40.2 ± 4.86 μ g/10 mg tissue/15 min after 7-9 days and 44.7 ± 3.31 after 14-16 days; its activity was lowest in Jensen sarcoma (21.8 ± 4.26 and 20.8 ± 3.60 , resp.). The activity of aspartate-aminotransferase was lowest in sarcoma M-1 (34.4 ± 1.53 μ g/mg tissue/hr) and highest in Jensen sarcoma (45.7 ± 3.44 μ g/mg tissue/hr). Thus, there is a direct relation between the tumor growth rate and hexokinase activity, while there is an inverse relation between the tumor growth rate and aspartate aminotransferase activity. The relation between alanine-aminotransferase activity and tumor growth rate was not clarified. Hydrocortisone caused decreases in body weight and inhibited the development of sarcomas. The weight decreased 15% in rats with sarcoma M-1, 18% in those with sarcoma 45, and 22% in rats with Jensen sarcoma. Hydrocortisone did not have any appreciable effect on enzyme activities in any of the three types of sarcomas.

3999 CHARACTERIZATION OF HUMAN LEUKEMIA AND BURKITT LYMPHOMA CELLS BY THEIR ACIDIC NUCLEAR PROTEIN PROFILES. (E.) Weisenthal, L. M. (U. Michigan Med. Sch., Ann Arbor) and R. W. Ruddon. *Cancer Res* 32(5):1009-1017, 1972.

Leukocytes were purified from peripheral blood from seven patients with acute or chronic leukemia and from normal donors. Leukemic lymphocytes were cultured in the presence of PHA (8 μ g/ml) in medium containing 10% fetal calf serum. Burkitt lymphoma (P₃J) cells were similarly maintained but without PHA. Nuclei were isolated from leukocytes by homogenization and acidic nuclear proteins (ANP) and nucleohistones were purified from nuclear sonicates. Examination of the ANP fraction from various leukemias was conducted by SDS-polyacrylamide gel electrophoresis. The banding patterns from these largely nondividing populations (paucity of high-molecular-wt. and majority of lower-molecular-wt. proteins) was quite different from the banding patterns of ANP of cultured Burkitt lymphoma cells, which contained a heterogeneous population of high-molecular-wt proteins and a comparatively small amount of lower-molecular-wt proteins. Some higher-molecular-wt protein bands were detectable in the myeloid leukemias which were not seen in the lymphoid leukemias. A correlation was found between the ANP binding pattern and "maturity" of lymphoid cells as

immature leukemic cells contained protein species that banded near the middle of the gels but more fully mature leukemic cells of the large lymphocyte type and normal donor lymphocytes showed smaller amounts of these proteins. Leukemic lymphocytes cultured with PHA increased ^3H -thymidine incorporation into DNA by 100-fold by the sixth day. At the same time, their ANP profile showed a progressive disappearance of low-molecular-wt proteins and a progressive appearance of high-molecular-wt proteins, a pattern similar to that of P₃J Burkitt lymphoblasts. The change in ANP profile preceded the increase in thymidine incorporation into DNA. A similar shift in ANP content was observed in PHA-stimulated normal donor lymphocytes.

- 4000 EFFECT OF HYPERGLYCEMIA ON TUMOR GROWTH IN RATS. (Rus.) Tagi-Zade, S. B. (Res. Inst. Roentgenol. Radiol. Oncol., Baku, USSR). *Vop Onkol* 17(11):75-80, 1971.

Sarcoma M₁ was transplanted s.c. into noninbred albino rats. Diabetes was first induced in one group of animals by two 15 mg/kg i.p. injections of alloxan three days apart; these rats were given 5% glucose with their drinking water and, ten days after the last dose of alloxan, received the tumor transplant. A second group of rats received glucose (2 mg/g/day s.c.) for ten days, starting seven days after tumor transplantation. A third group of rats received glucose (2 mg/g s.c.) six times a day for ten days, starting from the day of transplantation or seven days later. Injection of glucose once a day had no appreciable effect on tumor growth. Administration of glucose six times a day significantly reduced tumor weight, particularly when injections started on the day of transplantation. Maximum inhibition of tumor growth was observed in diabetic animals. Tumor necrosis was also more pronounced in diabetic rats than in those given six glucose injections per day. These findings support the hypothesis that inhibition of tumor growth in diabetic animals is a result of systemic changes in the carbohydrate and protein metabolism of the host and that tumor necrosis results from the successful competition of normal cells with cancer cells for glucose.

- 4001 COMPARISON OF ACTIVITY AND ISOZYME PATTERNS OF FOUR ENZYMES FROM HEPATOMAS OF DIFFERENT GROWTH RATES. (E.) Otani, T. T. (Natl. Cancer Inst., Bethesda, Md.) and H. P. Morris. *J Nat Cancer Inst* 47(6):1247-1253, 1971.

The activity and relative isozyme distribution of four enzymes--glutamic-oxalacetic transaminase (GOT), glutamic-pyruvic transaminase (GPT), malate dehydrogenase (MDH), and lactic dehydrogenase (LDH)--were determined in electrophoretically purified water extracts of normal liver cells from young (72-76 days) and old (172-212 days) Buffalo rats, from young (72-83 days) and old (184-217 days) ACI rats, and

from fast-growing (3924A), intermediate-growing (5123tc), and slow-growing (7793 and R₇) Morris hepatomas. Enzyme assays were performed by measuring the decrease in absorbance at 340 mμ accompanying the oxidation of NADH₂ to NAD. The normal levels of GOT (20.2-23.4 x 10³ spectrophotometric units/mg protein N), GPT (4.3-8.0 x 10³), MDH (89.0-103.6 x 10³), and LDH (48.8-59.0 x 10³) were unaffected by the age of the animals. Hepatic GPT was higher and hepatic LDH was lower in the ACI strain than in the Buffalo strain. Hepatoma GOT specific activities were inversely proportional to the rate of growth being lowest (5.5 x 10³) in 3924A and highest (30.4 and 38.9 x 10³ resp.) in 7793 and R₇. No detectable GPT activity was found in hepatomas 3924A and 5123tc. GPT levels of 7793 and R₇ were approximately the same as that of normal liver. MDH activity was apparently unrelated to growth rate; though lower than normal (61.9 x 10³) in the fast-growing 3024A tumor, it was in the range of levels of normal liver in hepatomas 5123tc, 7793 and R₇. LDH levels showed a direct relation to tumor growth rate when compared in a given strain, but did not appear to be correlated with growth rate if strain difference was disregarded, since 5123tc (generation time of 1.1 month) had about the same LDH level as R₇ (4.5 months). LDH levels of all tumors (except 3924A) were well below those of normal liver. Separation of isozymes by electrophoresis was noted with GOT (two peaks) and MDH (two or more peaks). LDH and GPT showed predominantly single peaks. No qualitative differences in mobility of the isozymes were seen between normal liver and hepatomas. The relative distribution of the isozymes of the different enzymes varied considerably among the tumors and each of the tumor enzyme activities differed from those of normal liver in the activity of at least one enzyme or isozyme. The fast-growing, poorly differentiated hepatoma 3924A showed the greatest deviation with five "abnormal" enzyme components out of six.

- 4002 METHYLATION OF PURIFIED TRANSFER RNA PREPARATIONS BY EXTRACTS DERIVED FROM RAT KIDNEY AND KIDNEY TUMOURS. (E.) Pegg, A. E. (Middlesex Hosp. Med. Sch., London, England). *Biochim Biophys Acta* 262(3):283-289, 1972.

The methylation of tRNA^{fMet}, tRNA^{Glu}, and unfractionated tRNA from *E. coli* K12 (methyl deficient) by normal rat kidney extracts and extracts from kidney tumors induced by dimethylnitrosamine is described. The tumor extract was two to three times more active than normal tissue extract in the presence of excess tRNA, expressed as pmoles methyl groups incorporated per mg protein per 15 min. With unfractionated tRNA as substrate maximal activity occurred with either 25 mM putrescine or 0.3 M NH₄⁺; 60% of this methylation rate was seen with 2 mM spermidine and 20% with Mg²⁺. tRNA^{Glu} showed maximal activity with NH₄⁺; it was almost inactive with Mg²⁺. tRNA^{fMet} was active with Mg²⁺ but maximal activity was seen with putrescine or spermidine. Unfractionated tRNA as substrate gave methylation products of 5-methylcytosine, N²-methylguanine, and

1-methyladenine; 5-methyluracil, N^2,N^2 -dimethyl-guanine, 1-methylguanine, and 7-methylguanine were also present. Tumor extracts produced two to four times as much base in the 15-min incubation period as did normal kidney extracts. Maximal incorporation of methyl groups into tRNA occurred when 1 μ g of unfractionated tRNA or 20 pmoles of tRNA^{fMet} or tRNA^{Glu} was incubated with 3 mg protein for 54 min. It is suggested that factors other than the specificity of the tRNA methylases were responsible for the degree of tRNA methylation found in the experiments.

4003 METHYLATION PATTERNS OF TRANSFER RNA FROM ASCITES HEPATOMAS. (E.) Inose, M. (Sasaki Inst., Tokyo, Japan), S. Miyata and Y. Iwanami. *Biochim Biophys Acta* 259(1):96-103, 1972.

In vivo methylation patterns were studied in ³H-methionine-labeled tRNA purified from mouse ascites hepatoma strains 13, 66, 108A and 7974. Paper chromatography of labeled hepatoma tRNA acid hydrolysates showed relatively low uracil and increased guanine plus cytosine compared to normal liver tRNA. Relative content of 1-methyladenine was 13 to 14% of total methyl counts in all hepatoma strains. Methylguanine content of hepatoma tRNA was generally decreased compared to that of normal liver tRNA. Analyses of the four methylated bases comprising the methylguanine fraction showed that, while 1-methylguanine, N^2 -methylguanine and N^2 -dimethylguanine tended to vary, 7-methylguanine content of all hepatoma strain tRNAs was lower than that of normal liver. The ratios of 7-methylguanine to 1-methylguanine in hepatomas were consistently lower than that in normal liver.

4004 FETAL-TYPE ISOENZYMES IN HEPATIC AND NON-HEPATIC RAT TUMORS. (E.) Farron, F. (Harvard Med. Sch., Boston, Mass.), H. H. T. Hsu and W. E. Knox. *Cancer Res* 32(2):302-308, 1972.

Isoenzymes of lactate dehydrogenase (LDH), aldolase and pyruvate kinase were analyzed by starch gel or Sepharose III cellulose polyacetate electrophoresis and by assay of enzyme activity. The enzymes were obtained from cell homogenates of fetal rat (NEDH) liver, normal and regenerating adult rat liver, adult kidney and a variety of transplanted Morris hepatomas, two renal tumors and one rhabdomyosarcoma, covering a range of growth rates. The single forms, LDH-5 (M monomer), aldolase A and pyruvate kinase K, predominated in fetal rat tissues. Although normal and regenerating adult liver also contained predominantly LDH-5, the prominent form in adult kidney was LDH-1 (H monomer). Aldolase B and the L and M forms of pyruvate kinase predominated in normal adult tissues. A new finding was the detection of the cathodic aldolase C in lactating rat mammary gland. This form was absent in the hepatomas studied. Tumors originating from each of the tissues studied contained mainly the fetal types of the three enzymes and lacked

the adult forms. Whereas isoenzyme patterns of the faster-growing, less-differentiated tumors were closest to the fetal forms, slower-growing tumors generally showed patterns intermediate between those of adult and fetal tissue.

4005 TRANSFER RIBONUCLEIC ACID METHYLASES OF NUCLEOLI ISOLATED FROM A RAT TUMOR. (E.) Liao, M. C. (M.D. Anderson Hosp. Tumor Inst., Houston, Tex.), C. M. O'Rourke and R. B. Hurlbert. *Biochemistry* 11(4):629-636, 1972.

Novikoff ascites hepatoma cells were harvested after five or six days' growth in Sprague-Dawley rats, and methylases capable of transferring ³H-methyl from labeled S-adenosyl-L-methionine to purine and pyrimidine bases of *E. coli* tRNA were extracted from purified nucleoli with 0.5 M NH₄Cl. These enzymes were compared with pH 5-precipitated tRNA methylases derived mainly from cytoplasmic or soluble portions of the cells. The isolated nucleoli contained a constant and significant proportion (5%) of the total cellular tRNA methylase activity when assayed with heterologous *E. coli* RNA as substrate. Both nucleolar and "cell-soluble, pH 5" preparations were similar in pH optimum (pH 9), ionic strength (maximum activity in 0.2 M NH₄Cl) and response to ATP concentration (maximum at 1 mM), but they differed somewhat in their response to NaF and MgCl₂. Homologous RNAs and synthetic polynucleotides were ineffective substrates for both enzymes. Major methylation products, identified by paper chromatography of tRNA hydrolysates, were the same for both preparations (1-methyl-adenine, 7-methylguanine, 1-methylguanine, N^2 -methylguanine, 5-methylcytosine, thymine and 5-hydroxymethyluracil). The relative proportions of the methylated bases, however, differed considerably between the two preparations. In nucleolar preparations, 69% of label was in methylcytosine and 15% in methylguanines, while in the cell-soluble fraction 13% was in methylcytosine and 60% in the guanine derivatives. When cells were labeled *in vivo* with [³H-methyl]-methionine, the patterns of labeling of endogenous 4-6S RNAs showed the same trend, with nucleolar label primarily in the cytosine derivatives and cytoplasmic label primarily in the guanine derivatives. The nucleolar tRNA methylation enzymes were therefore judged to be true components of the nucleoli and to form a distinct subgroup of the total cellular methylation enzymes.

4006 DEGENERATION OF THE PINEAL GLAND OF PATIENTS WITH CANCER. (E.) Hajdu, S. I. (Mem. Hosp. Cancer Allied Dis., New York, N.Y.), R. S. Porro, P. H. Lieberman and F. W. Foote, Jr. *Cancer* 29(3):706-709, 1972.

Gross and microscopic changes of the pineal gland in 275 cancer patients were studied. Multiple slit-like cystic cavities, gliosis, and large numbers of Rosenthal fibers were found in the enlarged pineal gland of 31 patients (mostly children and adolescents). Twenty-four of the 31 patients died with acute granu-

locytic or lymphocytic leukemia. The extent of the changes found suggest a chronic process and that damage to the pineal gland is nonreversible. Although changes were observed only in the pineal gland it is possible that this degenerative process may involve other parts of the nervous system.

- 4007 MORPHOGENESIS OF TWO IMMUNOLOGICALLY INDUCED MOUSE LYMPHOMAS. (E.) Krueger, G. R. (Nat'l. Cancer Inst., Bethesda, Md.) and U. I. Heine. *Cancer Res* 32(3):573-582, 1972.

Female BALB/c and DBA/2N mice were treated simultaneously with azathioprine and an antigen (LDH virus, tubercle bacteria, or bovine serum albumin). Experimental animals developed between 20 and 66% malignant lymphomas that were classified by light and electron microscopy as lymphoblastic types. The tumors developed in an atrophic thymus and subsequently spread to involve the remaining lymphoreticular and hemoreticular tissues, as well as nearly all other organs. Cytologically, the initial thymic tumor nodules did not differ from hyperplastic nodules of nonneoplastic lymphoblastic stem cells. Also, cells of a well-established tumor showed only slight differences from those of normal lymphoblastic stem cells, such as increased esterase activity and presence of cytoplasmic annulate lamellae. Virus particles (C-type) were identified by electron microscopy only in early tissue culture passages of the BALB/c lymphoma but not in the DBA lymphoma. All tumors were readily isotransplantable. Cell-free transplantation remained negative in all instances tried. The tumor grows in tissue culture as an established lymphoblast cell line.

- 4008 COLLATERAL SENSITIVITY OF RESISTANT LINES OF MOUSE LEUKEMIAS L1210 AND L5178Y. (E.) Schmid, F. A. (Sloan-Kettering Inst. Cancer Res., New York, N.Y.) and D. J. Hutchison. *Cancer Res* 32(4):808-812, 1972.

Mouse leukemias L1210 and L5178Y, and two sublines of each, which are resistant to various chemotherapeutic agents and show pronounced patterns of collateral sensitivity (i.e., by acquiring resistance to one agent, the cell becomes more sensitive to another), were studied. BDF₁ mice received i.p. implantations of the leukemia cells and sensitivity to single or multiple injections of chemotherapeutic agents was measured by median survival time (MST). Sensitivity to cytoxan, carbazilquinone, methotrexate, 6-mercaptopurine and cytosine arabinoside was greatly increased in the resistant sublines as compared to the parent lines. MST of all lines except the parental L1210 were shorter when mice received whole-body x-irradiation (400R) 24 hr prior to s.c. injection of leukemia cells. Growth potential of the six leukemia lines in x-irradiated homologous mice and in x-irradiated and

streptomycin-treated heterologous golden hamsters was inversely proportional to the sensitivity to the chemotherapeutic agents, indicating a decrease in oncogenic potential, rather than antigenic changes of the tumor cells. No uniform pattern in the distribution of chromosome numbers was associated with change in oncogenic potential.

- 4009 THE ORIGIN OF HUMAN EMBRYO LUNG CELLS IN CULTURE: A COMMENT ON CELL DIFFERENTIATION, *IN VITRO* GROWTH AND NEOPLASIA. (E.) Franks, L. M. (Imperial Cancer Res. Fund, London, England) and T. W. Cooper. *Int J Cancer* 9(1):19-29, 1972.

The ultrastructure of cells from 15 cell lines derived from human embryo lung tissue at 11 different transfer generations (2nd-19th) was examined with an electron microscope and compared with that of cells present in starting cell suspensions and explants. Differentiated epithelial cells were not seen after the 2nd transfer generation. Two predominant cell types were present in all cultures although the proportion of each type varied from culture to culture. These cells were morphologically similar to endothelial cells and pericytes present in the initial explants. Type 1 cells had rounded or bean-shaped nuclei with a thin rim of marginal chromatin. The cytoplasm contained some rough endoplasmic reticulum, many free ribosomes, a small Golgi zone, and relatively few other organelles. Cell processes were short and few in number. Type 2 cells had a more convoluted nucleus with a thicker peripheral chromatin layer and small clumps of nuclear chromatin. The Golgi zone was large and there were usually many lysosomes and autophagic vacuoles and often dilated cisternae of rough endoplasmic reticulum. These and previous observations on other cell lines suggest that many cell lines established from normal tissues, and some lines established from tumors, have the same two predominant cell types, which may be derived from the endothelium and pericytes of small blood vessels. Since some differentiated tumor cells with recognizable tissue markers can be maintained *in vitro* under similar conditions, it is concluded that "normal" and tumor cells must have similar metabolic pathways. Therefore, the "normal" cells may not be satisfactory control material for biochemical and other studies of normal and tumor cells. The ability of differentiated cells to become established *in vitro* is apparently associated with the development of neoplastic characters.

- 4010 PRODUCTION OF THE PLACENTAL-TYPE ALKALINE PHOSPHATASE ISOENZYME BY LUNG CANCER TISSUE. (E.) Kang, K.-Y. (Osaka U. Sch. Md., Japan), K. Higashino, M. Hashinotsume, Y. Takahashi, T. Aoki, E. Tsubura and Y. Yamamura. *Gann* 63(2):217-224, 1972.

Alkaline phosphatase was purified from primary lung

tumor and from lung and liver metastases from a 55-yr-old male with a poorly differentiated adenocarcinoma of the left lung and compared to alkaline phosphatase isolated from a placenta. Enzyme activity was determined by spectrophotometric measurement of the release of phenol from sodium phenyl phosphate, and analysis of the tumor enzyme was carried out by polyacrylamide gel thin-layer electrophoresis, by immunoelectrophoresis, and by immunodiffusion, using rabbit anti-placental alkaline phosphatase. Enzyme from lung cancer and metastatic tumor was found to be identical to that from human placenta in heat-inactivation kinetics and in gel electrophoretic and immunoelectrophoretic banding patterns. Both tumor and placental enzymes showed the same kinetics of inactivation by L-phenylalanine, L-leucine, urea, L-isoleucine, L-valine, L-cysteine·HCl, KH_2PO_4 , NaCN and EDTA. The K_m values for tumor and placental alkaline phosphatase were both 2.27×10^{-3} M, compared with 2.95×10^{-3} M for normal lung enzyme. No other enzymes assayed showed a change of activity in tumor tissue. Fluorescent antigen-antibody staining of sections of lung tumor and normal lung tissue showed that placental-type alkaline phosphatase was present only in tumor tissue. It was concluded that placental-type alkaline phosphatase might be synthesized in lung cancer cells.

Tohoku U., Sendai, Japan), H. Kikuchi, H. Saeki and S. Tsuiki. *Biochim Biophys Acta* 244:19-29, 1971.

Yoshida sarcoma, ascite hepatomas AH-66F and AH-130 and Ehrlich ascites carcinoma were transplanted i.p. into male Donryu rats and male dd mice. Five or ten days after implantation the tumor cells were harvested, incubated with glucosamine in the presence or absence of glucose and examined for rate of glucosamine consumption. The metabolism of glucosamine differed strikingly according to the concentration used. Yoshida sarcoma cells readily phosphorylated 2 mM glucosamine and transformed a large portion of the formed glucosamine 6-phosphate into glycogen and lactate, the latter being the major end product. Exposure of Yoshida cells to 2 mM glucosamine also resulted in a marked fall in ATP unaccompanied by a rise in ADP. When the cells were incubated with 0.5 mM glucosamine, formation of glucosamine 6-phosphate was delayed and the major end product was glycogen. The cellular level of adenine nucleotides was only slightly affected. These metabolic differences due to differences in glucosamine concentration arise primarily from a low affinity of hexokinase toward glucosamine. Consumption of glucosamine by Yoshida cells ceased completely in the presence of glucose. Although no glycogen was formed by Ehrlich ascites carcinoma, the pattern of glucosamine metabolism was similar for the other tumors. All tumors were rich in phosphoglucosamine isomerase, which appears to determine the rate of conversion of glucosamine to glycogen, lactate, and CO_2 in tumor cells.

4011 EVIDENCE FOR TRANSLATIONAL REGULATION OF SPECIFIC ENZYME SYNTHESIS BY N^6, O^2 -DIBUTYRYL CYCLIC AMP IN HEPATOMA CELL CULTURES. (E.) Wicks, W. D. (Natl. Jewish Hosp. Res. Ctr., Denver, Colo.) and J. B. McKibbin. *Biochem Biophys Res Commun* 48(1):205-211, 1972.

Dibutyryl cAMP has been shown to increase the rate of phosphoenolpyruvate carboxykinase (PEPCK) synthesis in cultured Reuber hepatoma (H35) cells. A two- to three-fold increase in incorporation of ^3H -leucine into PEPCK occurred as early as 1.5 hr after addition of dibutyryl cAMP (0.5 mM) to H35 cultures which had been transferred to serum-free medium 12-18 hr previously. Addition of actinomycin D, which has been shown to inhibit the early phase of dibutyryl cAMP-dependent stimulation of tyrosine transaminase (TT) in H35 cells, had no early inhibitory effect on PEPCK activity. As time progressed, however, inhibition of increasing intensity was observed. In contrast, actinomycin D could prevent PEPCK stimulation by dexamethasone. These results are consistent with the conclusion that the response of PEPCK to dexamethasone requires new RNA synthesis while that to dibutyryl cAMP does not. Dibutyryl cAMP may affect a post-transcriptional step in PEPCK synthesis. Superinduction of TT was observed after addition of high concentrations of actinomycin D with both dexamethasone and dibutyryl cAMP; PEPCK, however, did not exhibit this phenomenon with either indicator.

4013 THE GENERATION TIME OF HUMAN LEUKEMIC MYELOBLASTS. (E.) Greenberg, M. L. (Mount Sinai Sch. Med., City U. New York, N.Y.), A. D. Chanana, E. P. Cronkite, G. Giacomelli, K. R. Rai, L. M. Schiffer, P. A. Stryckmans and P. C. Vincent. *Lab Invest* 26(3):245-252, 1972.

Three patients with acute myelocytic leukemia, one with acute myelomonocytic leukemia and one with a morphologic blast crisis in chronic myelocytic leukemia were studied to determine the generation time of the leukemic myeloblasts. No patient received therapy during the experimental period. Each subject was injected i.v. with ^3H -thymidine followed by a series of bone marrow aspirations for autoradiographs. Myeloblasts were divided into large, medium and small size populations on the basis of micrometer measurements. As a rule, myeloblasts in DNA synthesis were larger than those in other phases of the cell cycle. Based on the kinetics of cell labeling, it was concluded that the larger myeloblasts divided to produce small myeloblasts. The large myeloblast populations in all patients had labeling indices of 30 to 51%, values similar to those reported for nonleukemic myeloblasts. The time required for DNA synthesis, determined from the wave of labeled mitoses and from a dual labeling autoradiography technique, was similar to or slightly longer than that reported for nonleukemic myeloblasts. Generation times,

4012 TRANSFORMATION OF GLUCOSAMINE TO GLYCOGEN AND LACTATE BY ASCITES TUMOR CELLS. (E.) Sukeno, T. (Res. Inst. Tuberculosis, Leprosy, Cancer,

estimated using the labeling indices of the large myeloblasts and DNA synthesis times, were 19.5 to 53.5 hr, values also similar to those reported for nonleukemic myeloblasts. No striking differences were observed between normal and leukemic myeloblasts with respect to the duration of the various phases of the cell cycle. It is possible that differences in the cell cycle of potential therapeutic advantage may be found at the stem cell level; however, such work is presently technically impossible.

- 4014 MALIGNANT TUMORS OF THE SPERMATIC CORD.
(E.) Malek, R. S. (Mayo Clinic, Rochester, Minn.), D. C. Utz and G. M. Farrow. *Cancer* 29(4): 1108-1113, 1972.

The diagnosis, treatment and prognosis of ten patients with sarcoma of the spermatic cord seen at the Mayo Clinic in a 39-year period (1932-1970) is presented. Eight of the ten patients had undergone a radical or simple orchiectomy elsewhere; the remaining two had a radical orchiectomy after a cord tumor was "shelled out". Three of the patients had an embryonal rhabdomyosarcoma confined to the cord; five had the same tumor invasive to the testis; one had a leiomyosarcoma, grade 4; and one a fibroblastic liposarcoma, grade 3. Treatment (surgical, chemotherapeutic and adjunct radiotherapy) was dependent on the degree of spread of metastases. The patients with tumors confined to the cord are among the longest survivors (1 1/2 to 39 yr). The prognosis for the invasive tumors is poor, but two patients are still living (2 to 2 1/2 yr). The patients with leiomyosarcoma and fibroblastic liposarcoma are alive 3 and 18 yr, resp., after the initial diagnosis.

- 4015 MATURATION PATHWAY FOR RIBOSOMAL RNA IN THE HeLa CELL NUCLEOLUS. (E.) Maden, B. E. H. (Dept. Biochem., U. Glasgow, Scotland), M. Salim and D. F. Summers. *Nature New Biol* 237(70):5-9, 1972.

The maturation pathway for rRNA in the HeLa cell nucleolus proposed by Weinberg and Penman was confirmed by "fingerprinting" T1 RNase plus alkaline phosphatase digests of mature 18S and 28S rRNA and nucleolar precursor RNA after *in vitro* labeling with ³H-methyl methionine. Using this technique, several unique 18S and 28S spots were resolved by two dimensional thin-layer chromatography. With only a few exceptions, the spots seen in fingerprints of digests of 45S and 41S precursor RNA molecules purified on sucrose density gradients corresponded to those of 18S and 28S fingerprints, indicating a nucleolar origin for rRNA. 32S fingerprints showed patterns similar only to those of 28S rRNA, confirming that 32S RNA is a unique precursor of 28S rRNA. Fingerprints of nucleolar 18-20S RNA corresponded to those of cytoplasmic 18S rRNA, thus indicating

a precursor-product relationship between these moieties.

- 4016 A STUDY OF MULTINUCLEATED TUMOR CELLS DEMONSTRATING THE EFFECT OF TRANSPLANT DURATION ON SERUM CHANGES IN CANCER-BEARING HAMSTERS. (E.) Gillespie, D. M. (Dept. Zoology, U. Vermont, Burlington) and D. F. Stevens. *Cancer Res* 32:1577-1579, 1972.

A cancer-induced change had previously been reported in the serum of hamsters bearing transplantable cheek pouch tumors. In the present study, the kinetics of appearance and disappearance of this serum change were studied. Female golden hamsters received an injection of $1.5 \times 10^6 \pm 10\%$ ascites tumor cells into the left cheek pouch. At various times thereafter, blood samples were drawn and tested for tumor-associated serum changes. The ability of serum to decrease the number of multinucleated tumor cells in an *in vitro* incubation assay was used as the criterion for the serum change. Sera from more than 90% of all hamsters receiving tumor cell injections were able to decrease the number of multinucleated tumor cells by 24 hr after tumor cell inoculation. Tumors were excised after three days when all sera exhibited activity. At varying times after tumor excision, serum samples were again drawn and tested. Serum activity was still present in all animals five days after tumor excision; however, the percentage decreased to 45.5% on day six and continued to drop until zero activity was reached 9 to 10 days after tumor excision. The appearance of a specific, cancer-induced serum change was probably related to the number of cells present in the host as serum from animals inoculated with only 1.0×10^6 cells was inactive up to four days after transplantation, even though small tumor nodules were present. If nodules were allowed to continue to grow, the serum eventually became active. Transplantation of 1.5×10^6 normal regenerating liver cells into female hamster cheek pouches failed to induce serum activity.

- 4017 SYNTHETIC RNA-DEPENDENT DNA POLYMERASE ACTIVITY IN NORMAL RAT LIVER AND HEPATOMAS. (E.) Ward, D. C. (Imperial Cancer Res. Fund Labs., London, England), K. C. Humphries and I. B. Weinstein. *Nature* 237:499-503, 1972.

A high level of synthetic RNA-dependent DNA polymerase (RD-DP) activity has been detected in a low-speed pellet fraction of normal Sprague-Dawley rat liver and dimethylaminoazobenzene-induced rat hepatoma crude cell homogenates. RD-DP activity, which was evidently located in nuclei or on large membrane fragments, was purified 200-fold by ammonium sulfate precipitation followed by fractionation on DNA-cellulose and Sephadex G-100 columns. The purified enzyme showed optimum activity with 0.5 mM Mn⁺⁺ at a pH

of 8.0 to 9.5. RD-DP used poly(dT)·poly(rA) and poly(rA)·poly(rU) as templates but showed little or no ability to incorporate ³H-TTP into DNA with poly d(A-T), poly r(A-U), native or denatured nicked and unnicked calf thymus DNA, or various "single-stranded" RNAs as templates. Crude homogenates of hepatomas had twice as much RD-DP activity per gm wet wt as did normal rat liver, when assayed with poly(dT)·poly(rA) or poly(rA)·poly(rU). However, both tissues had the same amounts of DNA-dependent DNA polymerase activity when assayed with poly d(A-T).

4018 A COMPARISON OF THE ETIOLOGIC FACTORS IN VIRAL HEPATITIS, CIRRHOSIS AND PRIMARY LIVER CANCER. (Fr.) Bertrand, E. (C.H.U., Abidjan, Ivory Coast), M. Lebras and B. Beda. *Bull Soc Pathol Exot* 64(3):251-259, 1971.

An epidemiological study of three liver diseases (hepatitis, cirrhosis and liver cancer) in Abidjan hospitals was conducted for evidence of an etiologic relationship between the three. Hepatitis was the most frequently occurring, with severe (hospitalized) cases constituting 3.84% of all hospital cases, with a 3.80% occurrence for cirrhosis cases and 1.60% for liver cancer. All the diseases occurred more frequently in men than women; the ratio of male to female cases was: for hepatitis, 3:1; for cirrhosis, 5.5:1, and for cancer, 11:1. Hepatitis occurred more frequently at an earlier age (20-30 yr) than cirrhosis and cancer (30-40 yr), with a second peak arising between 50-60 yr for cirrhosis where the alcoholic factor was important. The hepatitis and cirrhosis age distribution curves indicated cirrhosis of the 3rd and 4th age decade to be of hepatitic origin. Primary liver cancer epidemiology revealed development of this neoplasia to occur often in patients with a cirrhosis history. These epidemiologic findings seem to confirm the hypothesis, which has been advanced on clinical, anatomical and experimental grounds, that hepatitis, cirrhosis and liver cancer are etiologically related.

4019 CHROMOSOME 16: A SPECIFIC CHROMOSOMAL PATHWAY FOR THE ORIGIN OF HUMAN MALIGNANCY? (E.) Bender, M. A. (Dept. Radiol., Vanderbilt U., Nashville, Tenn.), M. A. Kastenbaum and C. S. Lever. *Brit J Cancer* 26(1):34-42, 1972.

An excess of E16 chromosomes was correlated with malignancy in a recent study of 17 human cell lines. The study employed a semi-automatic karyotyping system in which a computer program was used to classify chromosome arm length measurements from stylized tracings of actual chromosomal images. To test the accuracy of this method of karyotyping, chromosome arm lengths in a sample of 723 normal human cells from 100 normal subjects were measured by an experienced cytogeneticist. The human observer arrived at very different results from those obtained with the computer. Only 29% of chromosomes classified as E16 by the computer

were classified as E16 by the cytogeneticist. The computer method also failed to give correct average numbers of chromosomes in the various classes. It was concluded that the excess in number of E16 chromosomes detected in malignant human cells is a systematic artifact of the computer method of karyotyping.

4020 THE ABILITY OF TUMOR CELLS OF THE LYMPHO-RETICULAR SYSTEM TO GROW *IN VITRO*. (E.) Trujillo, J. M. (U. Texas M. D. Anderson Hosp. Tumor Inst., Houston), B. Drewinko and M. J. Ahearn. *Cancer Res* 32(5):1057-1065, 1972.

Cells from biopsies of lymph nodes (45 cases), spleen (seven cases), bone marrow (five cases) and peripheral blood (one case) of untreated patients with a variety of malignant diseases and from peripheral blood samples of two healthy donors were propagated in monolayer cultures or spinner flasks using Ham's F-10 medium supplemented with 20% fetal calf serum, vitamins, glutamine and penicillin. Cytological, electron microscope and chromosome studies were periodically performed while cultures remained viable. The growth span of cells was classified as short (< two months), early (two wk to six months) or long (> six months). A line was considered established when cells had been maintained in continuous culture for over one yr. Of the 58 cases, 96.5% grew as short-term cultures, 84.5% progressed to early cultures and 55.5% grew for longer periods. Only four cell lines were established as permanent cultures: T1, derived from the lymph node of a patient with lymphocytic lymphoma and maintained in culture over six yr; T3, from a lymph node of a patient with undifferentiated lymphoma; T4, from the bone marrow of a patient with acute leukemia; and T5, from a mixed lymphocytic culture from healthy donors. T1 and T4 produce immunoglobulin. As cultures became established, the cells changed from predominantly fusiform to a mixed population of round, elongated and polygonal cells which revealed morphological features of lymphocytoid, plasmacytoid and reticulum cells. Many of the round cells were intensely periodic acid-Schiff and pyronin positive. Most of the primary cultures had diploid or near-diploid karyotypes with occasional deletions or supernumerary chromosomes. Aneuploid cells in the near-tetraploid range began to emerge in long-term cultures. All four established lines were aneuploid. Cell lines which grew only for short periods maintained the ultrastructural characteristics of small lymphocytes (large N/C ratio, clumped chromatin, few organelles and sparse granules and vacuoles). Established lines, regardless of origin, had a small N/C ratio, finely dispersed chromatin, large nucleoli and numerous cytoplasmic organelles. C-type particles were seen in T1 cells and intranuclear herpes-like viral particles in T4 cells during the first few passages *in vitro*. However, subsequent cultures failed to exhibit viral particles. Cultures derived from malignancies generally grew for the longest periods (24 of 33 long-term cultures). Only one of eight cultures derived from normal tissues survived past eight months.

- 4021 HEMATOLOGIC AND CYTOGENETIC REMISSION OF BLASTIC TRANSFORMATION IN CHRONIC GRANULOCYTIC LEUKEMIA. (E.) Canellos, G. P. (Nat'l. Cancer Inst., Bethesda, Md.), V. T. DeVita, J. Whang-Peng and P. P. Carbone. *Blood* 38(6):671-679, 1971.

Thirty patients in the blastic phase of chronic granulocytic leukemia (CGL) were treated with a combination of vincristine (2 mg/sq m body surface/ i.v./wk) and prednisone (60 mg/sq m/orally/day). Increasing blast percentage and progressive leukocytosis are characteristic of this phase of CGL. Nine patients (30%) achieved complete or partial remission, eight a greater than 50% reduction in peripheral blast count only and 13 showed no antileukemic effects. A mean of 3.5 wk of therapy was required for remission to occur. In six patients achieving complete remission, the mean duration of the first remission was five months. Cytogenetic studies were performed on all patients in the chronic stage of the disease, and in 28 at the onset of the blastic transformation. All were Philadelphia chromosome-positive during the course of their disease. Nineteen patients entering the blastic phase showed a major aneuploid cell line (44-51 chromosomes) that was not present in the chronic stage. Complete hematologic remission was associated with the disappearance of the aneuploid cell lines and return of chromosomal number to that of the chronic phase. The findings in this series of patients indicate that hypodiploid cell lines are significantly more sensitive to the cytotoxic effects of vincristine and prednisone therapy. Subsequent relapse of the disease in previously remitted patients was associated with further degrees of aneuploidy, suggesting clonal evolution of a resistant cell line.

- 4022 DNA BIOSYNTHESIS BY ISOLATED MITOCHONDRIA STIMULATION BY CYTOPLASMIC FACTORS FROM NEOPLASTIC AND REGENERATING TISSUES. (E.) Kalf, G. F. (Jefferson Med. Coll., Philadelphia, Pa.), M. A. D'Agostino and G. R. Hunter. *Cancer Res* 31:2054-2058, 1971.

Postmicrosomal 105,000 x g supernatant fluids prepared from Walker R256 mammary carcinoma, mouse 6C3HED Gardner lymphosarcoma, 22 hr posthepatectomy regenerating rat liver and normal fetal and adult rat liver were studied with respect to their effect on the incorporation of radioactive thymidine triphosphate (dTTP) and deoxyadenosine triphosphate (dATP) into rat liver mitochondria *in vitro*. Incorporation into acid-insoluble material was stimulated by supernatant fractions from all tissues except normal adult rat liver. The stimulation was completely abolished by addition of ethidium bromide in low concentrations to the incubation mixture. The stimulatory activity was nondialyzable, heat labile, was not affected by DNase I, phosphodiesterase or RNase, and was precipitated by 30 to 50% ammonium sulfate. Fractionation of the crude rat hepatoma supernatant fraction on a DNA-cellulose column led to the separation of two active peaks which eluted at 0.15 and 0.30 M NaCl, resp. Analyses

of these proteins by polyacrylamide gel electrophoresis indicated that they were negatively charged at the pH at which they bound to the DNA-cellulose. Their ability to bind DNA in the presence of high salt concentrations indicated that the proteins recognized DNA as a specific substrate.

- 4023 DOPAMINE- β -HYDROXYLASE ACTIVITY IN MOUSE NEUROBLASTOMA TUMORS AND IN CELL CULTURES. (E.) Anagnoste, B. (New York U. Med. Ctr., N.Y.), L. S. Freedman, M. Goldstein, J. Broome and K. Fuxe. *Proc Nat Acad Sci USA* 69(7):1883-1886, 1972.

The activity of dopamine- β -hydroxylase was studied by radioassay and histochemical fluorescence in mouse C-1300 neuroblastoma tumors and in cultured cell lines derived from these tumors. Growing tumors possessed substantial hydroxylase activity which was proportional to the weight of the tumor. Hydroxylase activity in the serum of tumor-bearing A/J mice was markedly increased two wk after tumor implantation when compared with controls. Treatment of mice with 5-bromodeoxyuridine (3 mg/kg i.p. twice daily) caused a marked inhibition of tumor growth in the first two wk after the beginning of administration. Histochemical studies showed that 1-5% of the cells in the C-1300 neuroblastomas contained catecholamines and that catecholamine-containing processes terminated primarily around blood vessels of the tumor. Enzyme activity was also detected in two clonal lines of C-1300 neuroblastoma cells. The cell line which had the higher activity had the greater tendency to form axon-like processes. Tumors derived from mouse neuroblastoma cells maintained by continuous animal passage had a higher hydroxylase activity than did tumors derived from neuroblastoma cells cultured for prolonged periods *in vitro* and then implanted into mice.

- 4024 PROSTAGLANDIN PRODUCTION BY EXPERIMENTAL TUMOURS AND EFFECTS OF ANTI-INFLAMMATORY COMPOUNDS. (E.) Sykes, J. A. C. (Imperial Cancer Res. Fund, London, England) and I. S. Maddox. *Nature New Biol* 237(71):59-61, 1972.

BP8/P₁ ascites and solid tumor, and sarcoma 180 (S180) grown in male C3H/He and male Schneider mice, resp., were assayed for prostaglandin E₂-like activity by measuring the ability of purified tumor cell extracts to induce contraction of rat and chick gastrointestinal tissue. Prostaglandins were detected and estimated by gas-liquid chromatography. The mean prostaglandin E₂ content of two BP8/P₁ tumors was 1.98 ± 0.35 μ g/g wet weight of packed ascitic cells, and 2.29 ± 0.032 μ g/g of solid tumor. S180 tumor contained only 0.628 ± 0.132 μ g/g tumor. Daily i.p. injections of the anti-inflammatory agent indomethacin (5 mg/kg) reduced prostaglandin levels by 66% without appreciably affecting tumor growth. The effect of various anti-inflammatory compounds on prostaglandin synthesis was studied in an *in vitro* guinea pig system. Indo-

methacin (0.3 μ M) caused a 50% inhibition and fenclozic acid (ICI 54,450; 4 μ M) produced a 100% inhibition. However, an analog of fenclozic acid (ICI 54,501) which has no anti-inflammatory activity also completely inhibited prostaglandin synthesis, suggesting that inhibition of prostaglandin synthesis may not be the primary mode of action of anti-inflammatory compounds. Fenclozic acid at concentrations as high as 0.8 mM actually stimulated prostaglandin synthesis in BP8/P ascites cells.

4025 INCREASED EFFICIENCY OF EXOGENOUS MESSENGER RNA TRANSLATION IN A KREBS ASCITES CELL LYSATE. (E.) Metafora, S. (Coll. Phys. Surg., Columbia U., New York, N.Y.), M. Terada, L. W. Dow, P. A. Marks and A. Bank. *Proc Nat Acad Sci USA* 69(5):1299-1303, 1972.

10S mRNA's, purified by sucrose gradient centrifugation, from reticulocytes obtained from New Zealand rabbits, C57BL/6J mice treated with phenylhydrazine and humans with acquired hemolytic anemias were tested for their translation efficiency in a Krebs ascites cell S-30 lysate by measuring the rate of incorporation of isotopically labeled amino acids into acid-insoluble material. tRNA's from Krebs cells, rabbit reticulocytes and mouse liver showed similar abilities to increase protein synthesis by the Krebs lysate. Addition of mammalian tRNA increased protein synthesis by the Krebs lysate, both in the presence and absence of exogenous mRNA. Addition of a 0.5 M KCl wash fraction from rabbit reticulocyte ribosomes caused a three- to ten-fold increase in the extent of translation of natural mRNA's by Krebs S-30 lysates. In the presence of the wash fraction, one mole of rabbit or mouse 10S RNA directed the incorporation of 80 pmoles leucine into rabbit globin. Heating the wash fraction to 90 C for three min abolished its activity. Addition of human 10S RNA to the assay system including the wash fraction resulted in synthesis of equal amounts of α and β globin chains. Whereas addition of 1 A₂₆₀/ml of mouse 10S RNA resulted in the synthesis of five times more β than α chain, addition of 0.1 A₂₆₀/ml resulted in a symmetrical synthesis of the two chains. Stimulation by wash fraction was not specific for globin mRNA; it also increased the rate of protein synthesis in the endogenous system, and in the presence of encephalomyocarditis RNA and phage Q β RNA. A ribosomal wash fraction from Krebs ascites ribosomes inhibited protein synthesis, both with endogenous and exogenous mRNA. The rabbit reticulocyte wash fraction contained aminoacyl-tRNA synthetase activity, but results from amino acid incorporation studies indicated that the stimulation of protein synthesis by the wash fraction was probably due solely to aminoacyl-tRNA synthetase activity.

4026 THE EFFECT OF L-ASPARAGINASE ON THE NUCLEIC ACID METABOLISM AND CELL CYCLE OF HUMAN LEUKEMIA CELLS. (E.) Saunders, E. F. (Dept. Pediatrics, U. Toronto, Canada). *Blood* 39(4):575-580, 1972.

The effect of L-asparaginase on the cell cycle and on nucleic acid synthesis of leukemic cells was studied in four girls and one boy with acute lymphoblastic leukemia. L-asparaginase (2000 U/kg) was given i.v. over a 30 min period. Marrow samples were then taken and buffy coat volume and mitotic index were determined. DNA and RNA synthesis was assessed by autoradiography of marrow cells incubated *in vitro* with ³H-thymidine and ³H-uridine, resp. A rapid decline in buffy coat volume by 6 hr after drug administration indicated a lytic effect on leukemic cells which was too rapid to be cell-cycle dependent. More proliferating blasts were killed than were nonproliferating leukemia cells. Mitotic indices remained essentially unchanged for the first 6 hr but then decreased steadily to very low levels by 48 hr. In contrast, the mean ³H-thymidine labeling index decreased to less than 50% of the control during the first 6 hr. Thereafter, the labeling index and mitotic index curves declined in parallel. The fact that labeling indices decreased before mitotic indices indicated that L-asparaginase blocked the entry of leukemic cells into S phase. Cells already in S phase when the drug was administered appeared to continue into mitosis. In all patients, ³H-uridine labeling indices decreased to an average of 25% of control values by 48 hr. Uridine uptake was inhibited equally in both proliferative and nonproliferative blasts. Thus, the inhibition of RNA synthesis by L-asparaginase was independent of the proliferative activity of the marrow.

4027 GENETIC DETERMINANTS OF MORPHOLOGICAL DIFFERENTIATION IN HYBRID TUMORS. (E.) Weiner, F. (Dept. Tumor Biol., Karolinska Inst., Stockholm, Sweden), A. Cochran, G. Klein and H. Harris. *J Nat Cancer Inst* 48(2):465-486, 1972.

A hybrid cell line was produced by fusing cells of a line of L-cell-derived, fibroblastic, relatively non-tumorigenic cells (A9) with lymphocytic cells of a highly malignant, immunoresistant variant of an ascites lymphoblastoid lymphoma induced by Moloney leukemia virus (YACIR). The chromosome constitutions of the YACIR/A9 hybrid, and of tumors produced *in vivo* by hybrid cell inocula, were observed. Immediately after cell fusion the modal chromosome number of the YACIR/A9 hybrids was 92, almost exactly the sum of the modes of the two parent cells. During long-term (one yr) culture, the modal chromosome numbers of the hybrids fell progressively. YACIR/A9 hybrids had a low level of tumorigenicity compared to that of the YACIR parent cells. The tumors produced by the YACIR/A9 hybrid cells had chromosome patterns which fell into three groups. Group I tumors had relatively large chromosome numbers comparable with those of the hybrid line after reduction of chromosome number by long-term cultivation. Group II tumors had drastically reduced chromosome numbers (modes from 43-48). Group III tumors had a chromosome pattern intermediate between Groups I and II (modes between 50-68). The effects of chromosome loss on the morphology of tumors in Groups I, II and III were observed. Group III tumors

resembled the YACIR/A9 hybrids in being fibroblastic, some tumors showing lymphocytic as well as fibroblastic cells. Group II tumors showed a restored lymphocytic morphology resembling that of the YACIR parent line. Although lymphocytic morphology was suppressed when the lymphocytic YACIR cells were fused with fibroblastic A9 cells, the determinants of the lymphocytic morphology were apparently not lost in the hybrids. Rather, these determinants were carried cryptically from one generation to the next, until the loss of fibroblastic morphology permitted the lymphocytic differentiation to reappear.

4028 AMINO ACID ACTIVATION BY NUCLEOLI ISOLATED FROM THE NOVIKOFF ASCITES TUMOR. (E.)

Lamkin, A. F. (Dept. Biochem., U. Texas, Houston) and R. B. Hurlbert. *Biochim Biophys Acta* 272(2): 321-326, 1972.

The mechanism of the incorporation of amino acids into nucleolar protein was studied with nucleoli isolated by sucrose gradient centrifugation from homogenates of Novikoff ascites tumor cells. Each of 15 ^{14}C -labeled amino acids, added singly, was incorporated into acid insoluble material without need for added ATP, tRNA, complementary amino acids or other components of the cytoplasmic protein-synthesizing system. The activating enzymes corresponding to most of these amino acids (except proline and glutamic acid) were demonstrable by measuring the rate of amino acid hydroxymate formation when the nucleoli were incubated with the amino acid, NH_4OH and ATP. Thus, isolated Novikoff ascites tumor nucleoli appear to contain a tightly integrated protein synthesizing system which includes amino acid activating enzymes and tRNAs.

4029 DISTRIBUTION OF CERVICAL LYMPH NODE METASTASES FROM SQUAMOUS CELL CARCINOMA OF THE UPPER RESPIRATORY AND DIGESTIVE TRACTS. (E.)

Lindberg, R. (U. Texas M.D. Anderson Hosp., Houston). *Cancer* 29(6):1446-1449, 1972.

The topographical distribution of cervical lymph node metastases was determined in 1,155 patients with previously untreated squamous cell carcinomas of the head and neck. Subdiaphragmatic nodes were the most common site of metastases from primary tumors in the oral tongue and oropharynx. Nodes in the submaxillary triangle were the most common sites of metastases from tumors of the floor of the mouth. Tumors of the supraglottic larynx metastasized most commonly to the upper jugular nodes. Tumors of the nasopharynx metastasized most commonly to ipsilateral and contralateral nodes of the upper jugular. The incidence of cervical node metastasis increased as the size of the primary tumor increased in patients with tumors of the oral tongue, floor of mouth, retromolar trigone/anterior faucial pillar and soft palate. The incidence of nodal metastasis was not correlated with size of the primary tumor when the tumor was located in the tonsillar fossa, base of tongue, supraglottic larynx or hypopharynx.

4030 HISTOGENETIC BEHAVIOR OF TUMORS: III. POSSIBLE RELATIONSHIPS TO PATTERNS OF GLYCOLYSIS. (E.) Auersperg, N. (Cancer Res. Ctr., U. British Columbia, Vancouver, Canada). *J Nat Cancer Inst* 48(6):1589-1596, 1972.

Aerobic and anaerobic glycolysis was observed in two cell lines derived from a poorly differentiated squamous carcinoma of the human uterine cervix. One of the cell lines, C-4 I, resembled spinous cells and possessed more prominently than the other line (C-4 II) properties generally associated with malignancy. The less malignant line C-4 resembled normal basal cells. Under all conditions tested, aerobic and anaerobic, the glycolytic rate for C-4 I cells was higher than that for C-4 II cells. At cell densities ranging from early log phase to stationary phase, glucose utilization of C-4 I cells was 1.5-2.5 times higher than that of C-4 II cells; lactic acid accumulation of C-4 I cells was six to nine times higher than that of C-4 II cells at low cell densities and two to six times higher than that of C-4 II cells at higher densities. In C-4 I cells, lactic acid accumulation behaved as a fixed function of glucose utilization, independent of changes in the cell environment (e.g., changes in density, O_2 and CO_2 tension and pH). Changes in such environmental variables did modify glycolytic patterns in C-4 II cells. In addition, C-4 I cells evidenced anaerobic glycolysis. The greater glycolytic capacity of C-4 I cells was in keeping with the greater malignancy of these cells by other criteria.

4031 USE OF CELL SEPARATION AT 1 g FOR CYTOKINETIC STUDIES IN SPONTANEOUS AKR LEUKEMIA. (E.) Omine, M. (Natl. Cancer Inst., Bethesda, Md.) and S. Perry. *J Nat Cancer Inst* 48(3):697-704, 1972.

AKR strain mice with advanced spontaneous leukemia were injected once i.p. with 75-100 μCi ^3H -thymidine. At various times after injection, grossly enlarged thymuses were removed and prepared for 1-g sucrose gradient sedimentation. Cells were sedimented for two hr after which they were collected in 30 fractions of increasing cell size. The cohort of leukemic cells pulse-labeled with ^3H -thymidine showed consistent and continuous progress through the range of fractions of various cell sizes. A shift of radioactivity from larger to smaller cell fractions was seen by 12 hr after ^3H -thymidine injection. By 18 hr the major part of the leukemic cell cohort had completed a cell cycle (i.e., cell cycle time was 18 hr). From observations of cohort movement the average durations of the different cell cycle phases could be estimated. T_{G_1} was six hrs, the sum of the G2 and M phases was < four hrs, and T_{S} was a little more than eight hr. After multiple injections of ^3H -thymidine for 18 hr, most larger cells and nearly half the medium-sized cells were labeled, but most smaller cells remained unlabeled. Labeled cells made up about 60% of the whole population in multiple-labeling experiments. With longer labeling periods (to 87 hr) the labeling index of

the whole cell population increased as the number of labeled smaller cells increased. Some small cells remained unlabeled as the number of labeled smaller cells increased. However, some small cells remained unlabeled even after 87 hr of labeling.

4032 HUMAN LYMPHOBLASTOID CELL LINES: III. COCULTIVATION TECHNIQUE FOR ESTABLISHMENT OF NEW LINES. (E.) Steel, C. M. (Western Gen. Hosp., Edinburgh, Scotland). *J Nat Cancer Inst* 48(3): 623-628, 1972.

Cells from each of seven lymphoblastoid lines derived from patients with Burkitt lymphoma, infectious mononucleosis, viral gastroenteritis or chronic lymphatic leukemia were lethally irradiated (3,000 rads) and cocultivated with fresh blood leukocytes. The successful induction of cell lines from the mixed cultures was observed. Of the seven irradiated lines, all but three contained Epstein-Barr virus particles (EBV). The presence of EBV was correlated with effectiveness of irradiated cells as promoters of long-term growth in fresh leukocytes. None of the three EBV-negative lines was successful in establishing new cell lines; all of the EBV-positive lines were successful. With one exception, no new cell line was initiated from 24 mixed cultures using irradiated cells eight to 18 days postirradiation (the exception was a culture initiated using infectious mononucleosis cells nine days postirradiation). In contrast, 24 new lines were established from leukocytes mixed with irradiated cells on days zero to seven postirradiation. The likelihood of initiating a new cell line was not affected by the number of irradiated cells/5 ml mixed culture (within the range 0.5×10^6 – 5.0×10^6 irradiated cells). Likelihood of initiating a new line was improved, however, when the number of fresh leukocytes in mixed cultures exceeded 3×10^6 . Placental blood leukocytes grew more readily than those from older children or adults. Only eight of 23 new cell lines established showed EBV under the electron microscope. However, occult EBV infection was suspected in the other 15 lines. Of a total of 25 new cell lines established from mixed cultures, 22 were diploid (one was aneuploid and two were not examined cytogenetically). There was no evidence that EBV influenced the karyotypes of newly established lines.

4033 PROLIFERATIVE ACTIVITY OF HUMAN GRANULOCYTES, AS ESTIMATED QUANTITATIVELY BY IN VITRO COLONY FORMATION. (E.) Northup, J. D. (Nat'l Cancer Inst., Bethesda, Md.), J. M. Bull and P. P. Arbore. *J Nat Cancer Inst* 48(3):629-637, 1972.

Human marrow cells from normal subjects and patients with leukemia and anemia were cultured in a methylcellulose medium containing a colony-stimulating factor prepared from human embryo kidney cells. The number of colonies formed/10,000 nucleated marrow cells in cultures was observed after 10-12 days incubation. The number of colonies/10,000 nucleated mar-

row cells from ten normals was 0.9-5.8 (mean = 2.3). In patients with aplastic anemia, the range was 0-0.5 and in acute lymphoblastic leukemia patients the range was 0-10.1. Patients with acute myeloblastic leukemia showed 0-5.5 colonies/10,000 marrow-nucleated cells. Only a fraction of marrow cells in cultures were granulocyte precursors. The relationship between proportions of granulocyte precursors and the number of colonies produced was observed; as the proportion of granulocyte precursors increased the number of colonies/culture plate increased. Normals showed a mean of 6.0 colonies formed/10,000 granulocyte precursors. In acute lymphoblastic leukemia patients' marrow, the range of number of colonies/10,000 granulocytes was 0.4-126. The number of colonies formed/ml of marrow in ten normals' bone marrow cell cultures was 3,000-25,000/ml (mean = 12,000 colonies/ml). For patients with aplastic anemia or acute leukemia, the number of colonies/ml was normal or below normal.

4034 STUDIES ON THE GENETIC CONTROL OF CELL PROLIFERATION: I. CLEARANCE OF DNA-BOUND RADIOACTIVITY IN 19 INBRED STRAINS AND HYBRID MICE. (E.) Heiniger, H. J. (Jackson Lab., Bar Harbor, Me.), H. W. Chen, H. Meier, B. Taylor and L. S. Commerford. *Life Sci* 11(2):87-96, 1972.

Female mice of 19 different inbred strains and F₁ hybrids were given i.p. injections of tracer amounts of ¹²⁵I-5-iodo-2'-deoxyuridine (¹²⁵IUDR). Whole-body clearance of DNA-bound ¹²⁵I activity was observed from one min to 20 days after ¹²⁵IUDR injection. The DNA clearance curve was similar in shape for all strains, showing a continuous distribution of DNA turnover rates for all strains. Genetically related strains showed similar patterns of DNA clearance. On grouping strains for high and low rates of turnover, turnover was found to be associated with histocompatibility loci H-1, H-2 and H-4. No association was found between DNA turnover rate and occurrence, incidence or type of spontaneous tumorigenesis in mice.

4035 THE REPLICATION OF DNA IN MURINE LYMPHOMA CELLS (L5178Y). II. SIZE OF REPLICATING UNITS. (E.) Lehmann, A. R. (Chester Beatty Res. Inst., Sutton, England) and M. G. Ormerod. *Biochim Biophys Acta* 272(2):191-201, 1972.

The size of the replicating units of the DNA from murine lymphoma L5178Y cells was studied by direct measurement of the size of the growing DNA strands in sucrose gradients. Cells were pulse-labeled with ³H-thymidine and then irradiated with low doses of x-rays in order to introduce a small amount of DNA fragmentation, thus overcoming entanglement effects. Detailed analysis of the radioactivity profiles obtained on sedimentation of the resulting labeled DNA fragments in alkaline sucrose gradients has provided information about the size of the growing DNA strands. The results suggest that the replicating units have a single-strand molecular wt of

about 2×10^6 . Sometimes a much smaller population with a molecular wt of about 4×10^7 is also observed. On completion of replication the newly-synthesized strands are linked end-to-end, so that the molecular wt of the DNA strands in the G2 phase of the cell cycle is more than 10^9 , the upper limit of current measurement methods.

- 4036 METHYLATION OF DNA IN HUMAN CHRONIC GRANULOCYTIC LEUKEMIA CELLS. (E.) Tryfiates, G. P. (West Virginia U. Med. Ctr., Morgantown). *Life Sci* 11(5):229-236, 1972.

Methylation of DNA in human chronic granulocytic leukemic cells was studied. Granulocytes harvested from leukemic patients were incubated *in vitro* with ^3H -thymidine or methyl- ^3H methionine and the DNA was isolated and analyzed by CsCl centrifugation. DNA hydrolysates were analyzed by paper and Sephadex G-10 column chromatography for methylated bases using authentic methylated bases as standards. Upon incubation at 37°C , human leukemic granulocytes actively synthesized and methylated DNA. DNA synthesis occurred optimally after approximately one hr of incubation whereas DNA methylation was not maximal until about two hr of incubation, one hr after maximal DNA synthesis. The main DNA peak banded at $\rho = 1.6916 \text{ g/cm}^3$ from which an approximate guanine-cytosine content of 32.2% was calculated. Analysis of DNA hydrolysates showed the presence of 1-methyladenine and 5-methylcytosine. In addition, 1-methyl and/or 7-methylhypoxanthine, and 6-dimethylamino purine and/or 6-methyl mercaptopurine were tentatively identified.

- 4037 THE INFLUENCE OF THE THYMUS ON THE DEVELOPMENT OF TRANSPLANTED MAMMARY TUMOUR IN MICE. (E.) Belyaev, D. K. (USSR Acad. Sci., Novosibirsk) and E. V. Gruntenko. *Int J Cancer* 9(1):1-7, 1972.

High cancer C3H/He strain mice were thymectomized on the third day of life and given an engrafted C3H/He spontaneous mammary tumor at 60-75 days of age. The influence of thymectomy on tumor graft growth was observed. In thymectomized mice, tumor development was delayed and tumor weight was reduced. In a second set of experiments, C3H/He mice were given s.c. thoracic grafts of one, three or five thymuses from C3H/He mice ten days before receiving syngeneic mammary tumor grafts. Mice with one or three extra thymuses showed accelerated tumor growth. In the group with five extra thymuses, tumor growth was inhibited, suggesting that two factors exerting contrary effects on tumor development are present in the thymus. In a final group of experiments, five-day-old F_1 hybrids of matings between C3H/He females and C57BL (low cancer strain) males were thymectomized and the thymus was immediately replaced with a thymus from either a C57BL or a C3H/He donor. Tumors from C3H/He donors were grafted at two to three months of age. Replacement of the

hybrids' thymus by a C3H/He thymus did not effect the success of tumor grafting. Replacement of hybrid's thymus by a C57BL thymus significantly decreased grafting success; in 14 of 40 such mice, tumor grafts did not grow at all.

- 4038 CHROMOSOMAL MECHANISM FOR THE INDUCTION OF REVERSION IN TRANSFORMED CELLS. (E.) Block-Shtacher, N. (Weizmann Inst. Sci., Rehovoth, Israel), Z. Rabinowitz and L. Sachs. *Int J Cancer* 9(3):632-640, 1972.

A clone of hamster embryo cells transformed by polyoma virus was grown in culture at low cell density (10^3 cells/50 mm dish) at 41°C in the absence of a feeder layer to induce reversion of transformation. By six days of culture, the percentage of colonies in the cultured cells decreased from 79 to 33%, implying an increase in revertant cells, or cell variants. The increased frequency of variants was proportional to the increase frequency of aneuploid cells in reverting cultures. In six days of culture the percentage of diploid cells dropped from 78 to 33% and the percentage of aneuploid cells rose from 18 to 62%. Most aneuploid cells had chromosome numbers of 70-87. Changes in chromosome number and frequency of cell variants were not found in transformed cells seeded in culture at 10^5 cells/dish. The reverted state induced by growth at low cell density was unstable, but could be stabilized by incubation at 24°C . Chromosome numbers and percentage of colonies were not changed by incubation at 24°C . In studies of the number and size of nuclei in revertant cultures, it was found that binucleated cells developed which gave rise to cells with a large nucleus. The latter cells were apparently polyploid, and lost chromosomes to become aneuploid variant cells. Stabilization of the revertant state is probably associated with the production of the right type of stable aneuploid cells required for reversion.

- 4039 BONE MARROW RESPONSE TO ERYTHROPOIETIN IN POLYCYTHEMIA VERA AND CHRONIC GRANULOCYTIC LEUKEMIA. (E.) Zucker, S. (New England Med. Ctr. Hosp., Boston, Mass.), D. M. Howe and L. R. Weintraub. *Blood* 39(3):341-346, 1972.

The incorporation of exogenous iron into heme in bone marrow cells from four normals, three chronic granulocytic leukemia (CGL) patients and five polycythemia vera patients was observed. The effect of erythropoietin on iron incorporation was measured. Iron incorporation into heme by the normals' marrow ranged from $5.1-9.1 \mu\text{M}/10^6$ nucleated red blood cells. Iron incorporation into heme was above normal in all CGL and polycythemia vera patients. Erythropoietin (most effective dose = 0.6 U/ml marrow cells) increased heme incorporation of iron by 22.4-47.6% in normal marrows and by 35.5-38.4% in marrows of CGL patients. Erythropoietin did not significantly stimulate iron incorporation in marrows of polycythemia vera patients.

4040 L-ASPARAGINASE EFFECTS ON INTACT MURINE LEUKEMIA CELLS AND ON ISOLATED CELL PLASMA MEMBRANES. (E.) Kessel, D. (U. Rochester Med. Ctr., N.Y.) and H. B. Bosmann. *Biochem Biophys Res Commun* 48(1):35-40, 1972.

The effects of L-asparaginase were examined on intact and isolated membranes of asparaginase-sensitive L5178Y and resistant L5178Y/ASP lymphoma cells. Treatment of isolated L5178Y plasma membranes prelabeled *in vivo* with ^3H -L-fucose caused the release of small amounts of cell-surface glycoproteins into the supernatant fluid. Such a solubilization was not found using prelabeled intact L5178Y cells or prelabeled cells or plasma membranes of the resistant L5178Y/ASP line. Resistant L5178Y/ASP cells contained lower levels of cell-surface glycoprotein with papain-sensitive linkages than did the sensitive L5178Y cells, indicating that L-asparaginase resistance was a consequence of lower levels of plasma membrane glycoproteins. L-asparaginase (100 U/ml for 30 minutes) produced no alterations in intact or isolated L5178Y plasma membranes which could be seen using phase-contrast microscopy. Thus, the effect of asparaginase on sensitive cells could not be attributed to an immediate cell lysis resulting from an action of the enzyme on preformed membrane structures. The mechanism of asparaginase action may involve the inhibition of glycoprotein and protein synthesis required for the maintenance of membrane structure.

41 STIMULATING FACTORS FROM NORMAL AND LEUKEMIC CELLS LINES: SECRETION AND ACTION DURING ESTABLISHMENT OF A CELL LINE. (E.) Rosenfeld, (Paul-Brousse Hosp., Villejuif, France), A.-M. Guat and C. Choquet. *Rev Europ Etudes Clin Biol* (10):1036-1043, 1971.

11 lines from blood leukocytes of healthy donors and donors with acute myeloblastic, acute lymphoblastic and chronic lymphocytic leukemia were grown in medium 1640 RPMI. Stimulating factors were obtained in growth medium by growing normal or leukemic cells in it, and then centrifuging the conditioned medium. The presence of stimulating factors in supernatants of conditioned medium was demonstrated by inoculating supernatants with small numbers of homologous or homologous cells and observing their growth in conditioned medium. Inoculation of leukemic cells in new (unconditioned) medium and in conditioned medium which had supported autologous cells for three days showed that multiplication of leukemic cells is possible for inocula of less than 10^5 cells/ml in conditioned medium and that multiplication ceases in new media for inocula greater than 1×10^6 cells/ml. In general, conditioned media were able to support the growth of homologous or homologous normal and leukemic cells in small inocula which did not survive in unconditioned media. This effect was seen with supernatants of cell cultures incubated in medium with or without serum and in cell cultures incubated with medium alone, suggesting that stimulating factors in

conditioned medium were a cell product. The effect on cell growth of conditioned media was tested with media from normal and leukemic cultures 24 hr after initiation of culture, at various times during the descending phase which precedes establishment of cell culture and after establishment of cultures. Factors were produced by normal and leukemic cell cultures at the beginning of culture, but little or no factor was produced by cultures in the declining phase. After establishment of cultures, during the period of active culture growth, stimulating factors were again produced.

4042 FREQUENCY OF OCCURRENCE OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH PORPHYRIA CUTANEA TARDA IN LONG-TERM FOLLOWUP. (E.) Korđac, V. (Charles U., Prague, Czechoslovakia). *Neoplasma* 19(2):135-139, 1972.

Autopsies were performed on 36 patients with porphyria cutanea tarda (PCT), who had died over a 17-yr period at the Porphyric Dispensary, Prague. Of these, 33 were males. The average duration between clinical manifestation of the disease and death was 9 yr (a range of 2-20 yr). Cirrhosis of the liver was found in 63.9% of the autopsied cases. Hepatocellular carcinoma, which was invariably located in cirrhotic regions, was found in 47.2% of the cases, a rate 100 to 200 times that randomly found at autopsy in Czechoslovakia. The average duration of disease in PCT patients with cirrhosis and/or hepatocarcinoma was 11.7 yr, compared with 6.3 yr for those without liver disease at autopsy. These results tend to confirm the hypothesis that the extent of liver disease in PCT patients depends on the duration of the disease, although exceptions were observed.

4043 POLYNUCLEOTIDE LIGASE IN RAT TISSUES AND ASCITES HEPATOMA. (E.) Miyaki, M. (Cancer Inst., Tokyo, Japan) and T. Ono. *Cancer* 63(2):251-260, 1972.

DNA ligase and endonuclease activities were assayed concurrently in homogenates of regenerating rat liver and spleen and in sonicates of ascites hepatoma. ATP-dependent ligase activity, measured by the amount of covalently joined mixed ^3H -labeled dimer absorbed by hydroxyapatite, began to increase 15 hr after partial hepatectomy, reaching a value eight times that of normal liver by 37 hr. Endonuclease activity, determined by alkaline sucrose gradient centrifugation of native ^3H -DNA preincubated with tissue extract, was maximal in normal liver and minimal at 37 hr after partial hepatectomy. Up to a 2.5-fold higher ligase activity was observed in rat spleen and ascites hepatoma, AH-130 and AH-7974, than in regenerating liver. A reciprocal relationship between ligase and nuclease activities was also observed in these tissues. The ligase activity of nuclei was highest in both regenerating liver and AH-130, and the activities

of subcellular fractions of AH-130 were higher than those of corresponding fractions of regenerating liver. ATP-dependent ligase of regenerating liver and that of spleen were separated into two fractions by phosphocellulose column chromatography (eluting at 0.2 M and 0.3 to 0.35 M phosphate, resp.). Most of the ligase activity of ascites hepatoma AH-130, however, was recovered in a single peak eluting at 0.23 M phosphate. The ability of this fraction to rejoin nicked DNA in the absence of ATP suggested the presence of a ligase-AMP complex. The increase in ligase activity in regenerating liver at 37 hr corresponded to previously reported time of increased DNA synthesis and thymidine kinase activity, thus suggesting that ATP-dependent ligase may participate in DNA synthesis.

- 4044 OVARIAN TUMORS: AN EXTENSION OF THE PEUTZ-JEGHERS SYNDROME. (E.) Christian, C. D. (U. Arizona Coll. Med., Tucson). *Trans Amer Gynec Soc* 94:67-72, 1971.

The relationship between the Peutz-Jeghers syndrome and ovarian tumors is examined. In spite of the low incidence of occurrence of this syndrome, the coexistence of tumors in 15 of 125 reported cases is considered significant. A possible genetic defect reflected by the syndrome which in turn leads embryologically to either gastrointestinal polyposis or ovarian tumors is considered. Conceptually, data indicate that the embryological defect is thought to occur in the yolk sac entoderm which produces a primary germ cell which in turn induces a stromal proliferation resulting in the ovarian tumor. In light of a predilection for tumors in the presence of this syndrome, recommendation is made for continued documentation of the pathological nature of the ovarian tumors.

- 4045 JUVENILE THYROID CARCINOMA. (E.) Roeher, H. D. (U. Hosp., Heidelberg, Germany), R. Daum, M. Pieper and H. Rudolph. *J Pediatr Surg* 7(1): 27-31, 1972.

The diagnosis and treatment of nine juveniles with thyroid carcinoma are reported. The incidence, association with previous radiation therapy of the neck, and frequency of occurrence among juvenile females, in particular, are discussed. Treated children have relatively good prognosis with a satisfactory survival rate.

- 4046 SOME SIMILARITIES IN THE RESPONSES OF MICE TO PREGNANCY AND LEUKEMOGENESIS. (E.) Tyndall, R. L. (Oak Ridge Natl. Lab., Tenn.), J. A. Otten, M. R. Proffitt, N. D. Bowles and R. W. Tennant. *Int J Cancer* 9(3):584-594, 1972.

Pregnant BALB/c and AKR mice, AKR mice with spontaneous thymic lymphoma and mice of both strains with leukemia induced by inoculation with preparations of

Rauscher leukemia virus (RLV) were used as donors of serum and spleen cells for separation of serum proteins and nonspecific esterases by acrylamide gel electrophoresis. Serum protein patterns of RLV-infected leukemic mice and of spontaneously leukemic AKR mice resembled sera of pregnant normals in showing diminished second and third prealbumins, increased fourth prealbumin and increases in the protein migrating next to serum transferrin. Serum protein alterations in pregnant mice were similar to but more pronounced than those in leukemic mice. Sera from pseudopregnant mice, partially hepatectomized mice, mice inoculated with fetal tissue or mice infected with lactic dehydrogenase virus or pneumotropic mycoplasma did not show similar alterations, while sera of scalped mice did. Spleens from pregnant mice, like those of RLV-infected mice, showed marked hyperplasia in the red pulp. Germinal center formation was seen in spleen tissues from inbred (BALB/c) pregnant mice at 18-20 days of gestation and in postpartum spleens. Spleen esterases from RLV-infected mice showed decreased prealbumin and increased postalbumin esterase; a similar pattern was seen in esterases in spleens of pregnant mice. In related experiments, sera from pregnant or scalped rats and anti-murine leukemia virus rat serum showed a common precipitin line when reacted in double-diffusion tests with RLV from a variant RLV-infected JLS V5 cell line. Sera of virgin rats showed no such reactivity nor did cells from lines not infected with RLV.

- 4047 THE STIMULATION AND INHIBITION OF THE GROWTH CAPACITIES OF SPONTANEOUS TUMORS OF MAMMARY GLAND ORIGIN IN MICE (ADENOCARCINOMATA). (E.) Strong, L. C. (Leonell C. Strong Res. Fdn. Inc., San Diego, Calif.) and H. Matsunaga. *J Surg Oncol* 3(4):467-473, 1971.

A specially prepared liver extract with tumor-inhibiting powers was divided into two parts; one portion (REF) was stored in a refrigerator at -2.2 C and the other (ART) was stored at room temperature (22.2-28.9 C). Between 70-314 days after initial preparation of the liver extract, REF or ART was used to treat mice bearing spontaneous mammary adenocarcinomas. With each moiety there were obtained three reactions in regard to the growth capacity of spontaneous tumors over a 50 wk observation period. In sequence, these were (1) a stimulation of growth rate of tumors, (2) no effect on growth capacity of tumors and (3) a pronounced inhibition of tumor growth. REF given 262 or 314 days after its original preparation virtually abolished growth of tumors. The constituents of the tumor-inhibiting liver extract included adenosine, N^6 -methyladenosine and 5-methylcytidine.

- 4048 RETICULOSARCOMA AND AMYLOID DEVELOPMENT IN BALB/c MICE INOCULATED WITH SYNGENEIC CELLS FROM YOUNG AND OLD DONORS. (E.) Ebbesen, P. (Inst. Med. Microbiol. U. Copenhagen, Denmark). *J Nat Cancer Inst* 47(6):1241-1245, 1971.

Untreated BALB/c female mice (108) over 16 months old showed a markedly increasing risk of developing reticulosarcoma and leukemia with age increase; the mean survival time for the group was 20 months. Most of 116 males died with amyloidosis before reaching the age at which reticulosarcoma and leukemia became common in females, the mean survival time for males being 13 months. Intraperitoneal inoculation of one-month-old mice with 10^7 mixed viable thymus, spleen and lymph node cells from nonmalignant 4-month-old mice tripled the incidence of reticulum cell sarcomas and reduced the mean survival time. Mechanically disrupted cells from 14-month-old donors were less effective in inducing neoplasia. Inoculation one- and 14-month-old mice with viable cells from one-month-old donors did not increase tumor incidence. Extensive amyloid deposits were frequently seen in liver, kidney and thyroid of old mice, but were rarely observed in females. Inoculation of cells from old mice did not accelerate amyloid development.

49 INHIBITION OF LYMPHOCYTE TRANSFORMATION BY L-ASPARAGINASE IN ACUTE LEUKEMIA. (Sp.) Braudo Conesa, L. C. (Natl. Acad. Med. Buenos Aires, Argentina), S. Pavloski and J. C. Scornic. *Medicina* (5):434-439, 1971.

4063 CYTOMEGALOVIRUS INFECTIONS IN LEUKAEMIC CHILDREN. (E.) Caul, E. O. (Bristol Public Hlth. Lab., U. Bristol, England), V. A. Dickinson, A. P. Roome, M. G. Mott and P. A. Stevenson. *Int J Cancer* 10:213-220, 1972.

4064 MIDLINE MALIGNANT RETICULOSIS. A CLINICO-PATHOLOGIC ENTITY. (E.) Fechner, R. E. (Baylor Coll. Med, Houston, Texas) and D. W. Lamppin. *Arch Otolaryng* 95(5):467-476, 1972.

4065 CARCINOMA OF THE STOMACH. A FOLLOW-UP STUDY OF 1963 PATIENTS. (E.) Inberg, M. V. (Dept. Surgery, U. Turku, Finland), J. Vuori and S. J. Viikari. *Acta Chir Scand* 138:195-201, 1972.

- 4066 NEUROBLASTOMA: SYNCHRONIZATION OF NEURITE OUTGROWTH IN CULTURES GROWN ON COLLAGEN. (E.) Miller, C. A. (Albert Einstein Coll. Med., Bronx, N.Y.) and E. M. Levine. *Science* 177(4051): 799-802, 1972.
- 4067 MYELOID LEUKEMIA IN THE RABBIT (*ORYCTOLAGUS CUNICULUS*). (E.) Meier, H. (Jackson Lab., Bar Harbor, Maine), R. R. Fox and D. D. Cray. *Cancer Res* 32:1785-1787, 1972.
- 4068 METABOLIC ACTIVITIES OF MURINE CARCINOMA 755 AT VARIOUS STAGES OF GROWTH. (E.) Wheeler, G. P. (Southern Res. Inst., Birmingham, Ala.) and J. A. Alexander. *Cancer Res* 32:1761-1768, 1972.
- 4069 SERUM LIPOPROTEIN LEVELS IN PATIENTS WITH CANCER. (E.) Nydegger, U. E. (Blood Transfusion Service, Berne, Switzerland) and R. E. Butler. *Cancer Res* 32:1756-1760, 1972.
- 4070 ASSOCIATION OF EXOGENOUS RNA WITH NOVIKOFF HEPATOMA ASCITES CELLS. (E.) Okada, S. (Baylor Coll. Med., Houston, Texas) and H. Busch. *Cancer Res* 32:1737-1744, 1972.
- 4071 STUDIES ON ADRENOCORTICAL CARCINOMA OF RAT CYCLIC NUCLEOTIDE PHOSPHODIESTERASE ACTIVITIES. (E.) Sharma, R. K. (VA Hosp, Memphis, Tenn.). *Cancer Res* 32:1734-1736, 1972.
- 4072 INDUCTION OF TYROSINE AMINOTRANSFERASE AND AMINO ACID TRANSPORT IN MORRIS HEPATOMAS AND IN ADULT AND NEONATAL RAT LIVER. (E.) Reynolds, R. D. (Wisconsin Med. Ctr., Madison), D. F. Scott, V. R. Potter and H. P. Morris. *Cancer Res* 31:1580-1589, 1971.
- 4073 CARTESIAN DIVER STUDIES ON RESPIRATION AND GLYCOLYSIS OF HIGH AND LOW SARCOMA LINES. (E.) Lutton, J. D. (Dept. Biol., New York U., New York) and M. J. Kopac. *Cancer Res* 31:1564-1569, 1971.
- 4074 STIMULATION OR SUPPRESSION OF METASTASES WITH GRADED DOSES OF TUMOR CELLS. (E.) Vanwijck, R. R. (Harvard Med. Sch., Boston, Mass.), E. A. Godrick, H. G. Smith, J. Goldweitz and R. E. Wilson. *Cancer Res* 31:1559-1563, 1971.
- 4075 CONGENITAL TUMOR OF ATRIOVENTRICULAR NODE WITH COMPLETE HEART BLOCK AND SUDDEN DEATH. MESOTHELIOMA OR LYMPHANGIO-ENDOTHELIOMA OF ATRIOVENTRICULAR NODE. (E.) Lewman, L. V. (Inst. Path., Case Western Reserve U., Cleveland, Ohio), M. A. Demany and H. A. Zimmerman. *Amer J Cardiol* 29(4):554-557, 1972.
- 4076 ADENOMA OF THE RETINAL PIGMENT EPITHELIUM. HISTOCHEMICAL AND ELECTRON MICROSCOPIC OBSERVATIONS. (E.) Font, R. L. (Armed Forces Inst. Path., Washington, D.C.), L. E. Zimmerman and B. S. Fine. *Amer J Ophthalmol* 73(4):544-554, 1972.
- 4077 GONADOBLASTOMA. (HISTOENZYMOLGY AND ULTRASTRUCTURE). (Fr.) Laffargue, P. (Sch. Med. Marseille, France), B. Argemi, F. Laffargue and L. Adechy-Benkoel. *Ann Anat Path (Paris)* 16(4):467-476, 1971.
- 4078 HISTOCHEMICAL FEATURES OF GLYCOGEN IN TUMORS OF THE UTERINE CERVIX BEFORE AND AFTER RADIATION THERAPY. (Ger.) Kasabjan, S. S. (Volograd Med. Inst., USSR) and O. W. Sgibnewa. *Acta Histochem* 42(2):213-216, 1972.
- 4079 ACUTE LEUKEMIA WITH MYELOFIBROSIS. (Fr.) Zittoun, R. (Hotel-Dieu Hosp. Paris, France), J. Diebold and N. C. Gorin. *Nouv Rev Franc Hemat* 12(2):229-240, 1972.
- 4080 ELECTRON MICROSCOPIC VISUALIZATION OF CARBOHYDRATE COMPONENTS IN THE GLYCOCALYX OF TUMOR CELLS USING CONCAVALIN A. (E.) Roth, J. (Inst. Path., Friedrich-Schiller-U. Jena, Germany), H. W. Meyer, F. Bolck and D. Stiller. *Exp Pathol* 6(3/4):189-192, 1972.
- 4081 LYMPHATIC DISSEMINATION OF CANCER CELLS. (E.) Weissleder, H. (German Clin. Diagn., Wiesbaden). *Lymphology* 5:51-52, 1972.
- 4082 MACROMOLECULAR SYNTHESIS, GLUCOSE UTILIZATION AND LACTATE PRODUCTION OF EHRICH ASCITES TUMOR CELLS SERIALY CULTIVATED IN MEDIA WITH INCREASED NaCl CONTENT. (E.) Schachtschabel, D. O. (Physiol. Chem. Inst., Phillips U., Marburg, Germany) and E. Kürschner. *Exp Cell Res* 71(2):338-344, 1972.
- 4083 ASPARTYL TRANSFER RNA PROFILES IN NORMAL AND CANCER CELLS. (E.) Briscoe, W. T. (U. Texas M. D. Anderson Hosp. Tumor Inst., Houston), W. Taylor, A. C. Griffin, R. Duff and F. Rapp. *Cancer Res* 32:1753-1755, 1972.
- 4084 A SURFACE 3'-EXONUCLEASE OF NOVIKOFF HEPATOMA ASCITES CELLS. (E.) Crooke, S. T. (Baylor Coll. Med., Houston, Texas), S. Okada and H. Busch. *Cancer Res* 32:1745-1752, 1972.
- 4085 OCCULT SEMINOMA OF THE TESTIS MASQUERADING AS PRIMARY EXTRAGONADAL GERMINAL NEOPLASMS. (E.) Meares, E. M., Jr. (Stanford U. Sch. Med., Calif.) and E. M. Briggs. *Cancer* 30(1):300-306, 1972.

- 4086 A PROSPECTIVE STUDY OF ANTI-CANDIDA INTERFERING FACTOR IN LEUKEMIC PATIENTS. (E.) Preisler, H. D. (Nat'l. Cancer Inst., Bethesda, Md.), I. F. Hasenclever, E. S. Henderson, J. K. Smith and D. B. Louria. *Cancer* 30(1):294-299, 1972.
- 4087 COMPARATIVE HIGH-RESOLUTION ELECTROPHORESIS OF TUMOR HISTONES: VARIATION IN PHOSPHORYLATION AS A FUNCTION OF CELL REPLICATION RATE. (E.) Balhorn, R. (Dept. Biochem., U. Iowa, Iowa City), I. Balhorn, H. P. Morris and R. Chalkley. *Cancer Res* 32:1775-1784, 1972.
- 4088 AN AMELANOTIC VARIANT OF B16 MALIGNANT MELANOMA. (E.) Pasztor, L. M. (Oregon Regional Primate Res. Ctr., Beaverton) and F. Hu. *Cancer Res* 32:1769-1774, 1972.
- 4089 A COMPARATIVE BIOCHEMICAL STUDY OF ALKALINE PHOSPHATASES IN NORMAL AND LEUKEMIC CELLS. (E.) Neumann, H. (Weizmann Inst. Science, Rehovot, Israel), K. J. Wilson, R. Hauck-Granoth and N. Haran-Ghera. *Cancer Res* 31:1695-1701, 1971.
- 4090 TRANSCRIPTION OF WALKER 256 CARCINOSARCOMA CHROMATIN. (E.) Kostraba, N. C. (Biol. Dept., State U. New York, Buffalo) and T. Y. Wang. *Cancer Res* 31:1663-1668, 1971.
- 4091 AMINO ACID REQUIREMENTS *IN VITRO* OF HUMAN LEUKEMIC CELLS. (E.) Ohnuma, T. (Roswell Park Mem. Inst., Buffalo, N.Y.), J. Iligunda and J. F. Holland. *Cancer Res* 31:1640-1644, 1971.
- 4092 LYSOSOMAL AND NONLYSOSOMAL ENZYME ACTIVITIES OF MORRIS HEPATOMAS. (E.) Amberger, R. J. (Cleveland Clin. Fdn., Ohio), H. Hozumi and H. P. Morris. *Cancer Res* 31:1632-1639, 1971.
- 4093 BENIGN CHONDROBLASTOMA. A STUDY OF 125 CASES. (E.) Dahlin, D. C. (Mayo Clinic, Rochester, Minn.) and J. C. Ivins. *Cancer* 30(2):411-413, 1972.
- 4094 PLASMACYTOMA OF THE UPPER AIR AND FOOD PASSAGES. (E.) Kotner, L. M. (Mass. Gen. Hosp., Boston) and C. C. Wang. *Cancer* 30(2):418-419, 1972.
- 4095 HEXOKINASE ISOZYME PATTERNS OF HUMAN UTERINE TUMORS. (E.) Kikuchi, Y. (Nat'l. Cancer Ctr. Res. Inst., Tokyo, Japan), S. Sato and T. Sugimura. *Cancer* 30(2):444-447, 1972.
- 4096 SALIVARY GLAND LESIONS IN CHILDREN. A SURVEY OF 430 CASES. (E.) Krolls, S. O. (Armed Forces Inst. Path., Washington, D.C.), J. N. Trodahl and R. C. Boyers. *Cancer* 30(2):459-469, 1972.
- 4097 CARCINOMA OF THE BREAST IN CHILDHOOD. (E.) Oberman, H. A. (U. Michigan, Ann Arbor) and P. J. Stephens. *Cancer* 30(2):470-474, 1972.
- 4098 JUVENILE MYELOID LEUKEMIA WITH FETAL ERYTHROPOIESIS. (E.) Shapira, Y. (Hadassah Med. Sch., Jerusalem, Israel), A. Polliack, G. Cividalli and E. A. Rachmilewitz. *Cancer* 30(2):353-357, 1972.
- 4099 REPRESSION OF PROPAGATION OF EHRlich ASCITES TUMORS BY MEANS OF ATTENUATING TUMOR CELLS. (E.) Maekawa, K. (Fac. Agriculture, Kyushu U., Fukuoka, Japan) and M. Kushibe. *Cancer* 30(2):366-372, 1972.
- 4100 CALCIFYING EPITHELIAL ODONTOGENIC TUMOR. A HISTOCHEMICAL AND ULTRASTRUCTURAL STUDY. (E.) Chaudhry, A. P. (Sch. Med., State U. New York, Buffalo), C. T. Hanks, C. Leifer and E. A. Gargiulo. *Cancer* 30(2):519-529, 1972.
- 4101 METABOLISM OF BONE MARROW LEUKOCYTIC ELEMENTS IN CHRONIC MYELOID LEUKEMIA. (Rus.) Lapotnikov, V. A. (I. P. Pavlov Med. Inst. Leningrad, USSR), N. P. Lebedeva, I. G. Moskalik, I. A. Onushchenko and L. V. Filev. *Probl. Gemat* 17(2):3-6, 1972.
- 4102 HISTOCHEMICAL ENZYME FINDINGS IN A REPEATEDLY TRANSPLANTED NERVE TUMOR OF THE RAT. (Ger.) Osske, G. (Acad. Med. Erfurt, Germany) and R. Warzok. *Exp Path* 6(3/4):145-150, 1972.
- 4103 EXPERIMENTAL STUDIES ON TUMOR-DETERMINED BONE DETERIORATION. (Ger.) Rath, F. W. (Inst. Path. Martin-Luther U. Halle-Wittenberg, Germany). *Exp Path* 6(3/4):121-129, 1972.
- 4104 PRIMARY CARCINOMA OF THE URETER: CASE REPORT AND SURVEY OF 294 CASES REPORTED IN JAPAN. (Jap.) Washida, H. (Med. Sch. U. Nagoya, Japan) and K. Ueda. *Acta Urol Jap* 17(12):755-765, 1971.
- 4105 SOME FEATURES OF THE CANCER AND LEUKEMIA ASSOCIATION. (It.) Benini, G. (C. Forlanini Reg. Hosp. Rome, Italy) and F. Giordano. *Riv Tuberc Mal App Resp* 19(2):78-85, 1971.
- 4106 NEOPLASTIC AUTOPHAGY. BIOCHEMICAL STUDIES ON THE PATHOGENESIS OF PRIMARY LUNG

- CANCER CAVERNS. (It.) Cattaneo, C. (C. Forlanini Reg. Hosp. Rome, Italy) and U. Fantoli. *Riv Tuberc Mal App Resp* 19(2):71-77, 1971.
- 4107 CHANGES OF THE EXOCRINE PANCREAS FUNCTION IN PATIENTS WITH LEUKEMIA. (Rus.) Mitropolsky, A. N. (S. M. Kirov Acad. Mil. Med., Leningrad, USSR) and K. A. Sidorov. *Ter Arkh* 44(2):24-28, 1972.

- 247 CYTOPLASMIC RNA IN IMMUNOGLOBULIN-SECRETING MYELOMA TUMOR CELLS: I. IDENTIFICATION AND CHARACTERISTICS OF A CLASS OF HETEROGENEOUS RNA. (E.) Kimmel, C. B. (Dept. Biol., Oregon, Eugene) and C.-Z. Lu Wang. *Biochim Biophys Acta* 29(3):397-412, 1972.
- 248 COMPARISON OF THE SPECIFICITY AND EXTENT OF *IN VITRO* METHYLATION BY GUANYLATE RESIDUE-SPECIFIC TRANSFER RNA METHYLASES ISOLATED FROM ASCITES HEPATOMA, 3'-METHYL-4-DIMETHYLAMINO-2-TOBENZENE-INDUCED HEPATOMA, AND NORMAL RAT LIVER. (E.) Kuchino, Y. (Natl. Cancer Ctr. Res. Inst., Tokyo, Japan), H. Endo and S. Nishimura. *Cancer Res* 32(6):1243-1250, 1972.
- 249 CONTRIBUTION TO THE BEGINNING OF STROMAL INVASION IN CERVICAL CARCINOMA. (Ger.) Kuchner, J. (City Hosp. Vienna-Lainz, Austria) and J. H. Holzner. *Geburtsh Gynaek* 175(3):209-217, 1971.
- 250 GIANT CELL MORPHOLOGY IN MACROCELLULAR SARCOMAS OF THE BRAIN. (Pol.) Maszkiewicz, H. (Neurol. Clin., Warsaw Acad. Med., Poland) and E. Spychalski. *Neuropat Pol* 14(4):371-376, 1971.
- 251 URINARY HYDROXYPROLINE, ALKALINE PHOSPHATASE AND SERUM PHOSPHORUS LEVELS IN PATIENTS WITH BONE NEOPLASIA. (Pol.) Radom, S. (M. Sklodowska-Curie Inst. Oncol., Warsaw, Poland), Z. Zulawska and D. Golebiowska. *Nowotwory* 21(4):267-273, 1971.
- 252 DIGITAL METASTASES OF A GRAWITZ TUMOR. (Cz.) Kovarik, V. (Reg. Inst. Pub. Health, Dept. Radiol., Prachatice, Czechoslovakia). *Czech Radiol* 25(6):277-279, 1971.
- 253 CHROMOSOMES IN ADENOMATOUS HYPERPLASIA AND IN ENDOMETRIAL ADENOCARCINOMA. (Ger.) Villanilla-Musoles, F. (Women's Clin. U. Valencia, Spain). *Geburtsh Gynaek* 175(3):218-225, 1971.
- 254 THE KINETICS OF GLYCEROL AND DIMETHYL SULFOXIDE IN CULTURED LEUKEMIC AND BURKITT LYMPHOMA CELLS. (E.) Niwayama, G. (Sch. Med., U. California, Los Angeles). *Tohoku J Exp Med* 106(1):1-30, 1972.
- 4255 THE ROLE OF CERTAIN SCINTISCANNING METHODS IN THE STUDY OF LUNG TUMORS. (Fr.) Trinci, M. (Inst. Radiol., U. Rome, Italy), G. Cantarano and E. Falcetti. *Gaz Int Med* 76(20):1255-1269, 1971.
- 4256 CERTAIN ROENTGEN-MORPHOLOGICAL PECULIARITIES OF VASCULARISATION OF CANCER METASTASES IN THE LIVER. (Rus.) Rozenstrauch, L. S. (Moscow Inst. Radiol. Res., USSR), L. L. Kapuller and R. L. Magazannik. *Eksper Khir Anest* (5):38-40, 1971.
- 4257 PRIMARY CARCINOMA OF THE LIVER. (Siamese). Plengvanit, U. (Pacific-Congress of Gastroent., Melbourne, Australia). *Siriraj Hosp Gaz* 23(9):1272-1293, 1971.
- 4258 THE BRAIN SPECIFIC PROTEINS S₁₀₀ AND 14.3.2 IN EXPERIMENTAL BRAIN TUMORS OF THE RAT. (E.) Stavrou, D. (Dept. Vet. Med. U. Munchen, Germany), K. G. Haglid and W. Weidenbach. *Z Ges Exp Med* 156(3):237-242, 1971.
- 4259 EXPRESSION OF DIFFERENTIATED FUNCTIONS IN HEPATOMA CELL HYBRIDS: INDUCTION OF MOUSE ALBUMIN PRODUCTION IN RAT HEPATOMA-MOUSE FIBROBLAST HYBRIDS. (E.) Peterson, J. A. (Natl. Sci. Res. Ctr., Gif-sur-Yvette, France) and M. C. Weiss. *Proc Nat Acad Sci USA* 69(3):571-575, 1972.
- 4260 ALTERATIONS IN THE SERUM AMINO ACID COMPOSITION OCCURRING IN PATIENTS WITH ACUTE LEUKEMIA. (Rus.) Abramovich, A. B. (Ctr. Inst. Hemat. Blood Transf., Moscow, USSR) and L. G. Kovaleva. *Probl Gemat* 16(12):22-26, 1971.
- 4261 MALIGNANT RETROPERITONEAL NEURINOMA. (It.) Telleski, S. (Inst. Path. Anat. Histol. U. Florence, Italy). *Arch de Vecchi* 56(1):183-200, 1971.
- 4262 BLOOD HYALURONIDASE AND HYALURONIC ACID LEVELS IN PATIENTS WITH HYDATID MOLE OR CHORIONEPITHELIOMA. (Rus.) Gomeniuk, I. P. (H. I. Pirogov Med. Inst. Vinnista, USSR). *Akush Ginek* 47(12):52-53, 1971.
- 4263 THE QUANTITATIVE FEATURES OF BASOPHILIC AND EOSINOPHILIC GRANULOCYTES IN LEUKEMIC CHILDREN. (Ger.) Blau, H.-J. (Children's Clin. U. Rostock, Germany). *Folia Haemat (Leipzig)* 96(3/4):300-307, 1971.
- 4264 HISTOENZYMOLOGIC STUDIES ON CELL METABOLISM IN INTRACRANIAL TUMORS. (Fr.) Brotchi,

- J. (Neurol. Surg. Anat. Serv., U. Liege, Belgium). *Acta Neurol Belg* 72(1):5-17, 1972.
- 4265 GASTRIC METASTASES OF A SKIN MELANOMA. (Rus.) Klement'yeva, L. S. (Chudnovskiy Clin. Hosp., USSR) and M. R. Makarov. *Vestn Rentgen Radiol* 47(1):83-84, 1972.
- 4266 ALKALINE PHOSPHATASE ACTIVITY IN GRANULOCYTES OF PATIENTS WITH CHOLECYSTITIS AND CHOLANGITIS, OBSTRUCTIVE JAUNDICE AND NEOPLASMS OF THE LIVER. (E.) Kusch, F. (Voivodeship Hosp. Opole, Poland). *Pol Med J* 10(5):1102-1111, 1971.
- 4267 OVARIAN TUMOURS: A CLINICAL REVIEW. (E.) Ghose, N. (Chittaranjan Seva Sadan Coll. Obstetrics, Gynaecology Child Hlth., Calcuta, India). *Punjab Med J* 21(1):21-25, 1971.
- 4268 CANINE MALIGNANT MAMMARY TUMOURS. I. SARCOMAS. (E.) Misdorp, W. (Netherlands Cancer Inst., Amsterdam), E. Cotchin, J. F. Hampe, A. G. Jabara and J. von Sandersleben. *Vet Path* 8(2):99-117, 1971.
- 4269 SOME OBSERVATIONS ON THE PATHOLOGY AND NATURAL HISTORY OF UROTHELIAL NEOPLASMS. (E.) Schade, R. O. K. (Newcastle Gen. Hosp., Newcastle upon Tyne, England). *Beitr Path Bd* 145(4):325-335, 1972.
- 4270 MODAL DEOXYRIBONUCLEIC ACID VALUE AND SURVIVAL IN CARCINOMA OF THE BREAST. (E.) Atkin, N. B. (Mount Vernon Hosp., Northwood, England). *Brit Med J* 1(5795):271-272, 1972.
- 4271 NATURALLY OCCURRING AND INDUCED LEVELS OF AMINO ACID TRANSPORT AND TYROSINE AMINOTRANSFERASE IN RATS BEARING MORRIS HEPATOMAS. (E.) Scott, D. F. (Med. Ctr., U. Wisconsin, Madison), F. R. Butcher, V. R. Potter and H. P. Morris. *Cancer Res* 32(10):2127-2134, 1972.
- 4272 GLYCOCALYX OF TUMOR CELLS. (E.) Roth J. (Inst. Path., Friedrich-Schiller-U., Jena, Germany), D. Stiller and F. Bolck. *Exp Path* 6(1):35-46, 1972.
- 4273 CALCIFIED (PSAMMONA) BODIES IN ALVEOLAR CELL CARCINOMA OF THE LUNG. (E.) Gupta, P. K. (All-India Inst. Med. Sci., New Delhi, India) and K. Verma. *Acta Cytol* 16(1):59-62, 1972.
- 4274 SERIAL ESTIMATION OF SERUM, URINE, AND LEUKOCYTE MURAMIDASE (LYSOZYME) IN MONOCYTIC LEUKEMIA. (E.) Ohta, H. (Nagoya U. Sch. Med., Japan) and H. Nagase. *Acta Haemat* 46(5):257-266, 1971.
- 4275 ASSOCIATION OF MULTIPLE HAEMATOLOGICAL DISORDERS (ACUTE MYELOBLASTIC LEUKAEMIA, PARAPROTEINAEMIA, AND THALASSAEMIA) IN A 46,XX/46,XXqi FEMALE. (E.) Castoldi, G. L. (Inst. Internal Med., U. Ferrara, Italy), G. D. Grusovin, G. L. Scapoli and R. Spanedda. *Acta Haemat* 46(5):294-306, 1971.
- 4276 MALIGNANCY AND IMMUNOSUPPRESSION: RENAL HOMOTRANSPLANTATION IN PATIENTS WITH PRIMARY RENAL NEOPLASMS. (E.) Belzer, F. O. (Dept. Surg., U. California, San Francisco), R. T. Schweizer, S. L. Kountz and A. A. Delorimier. *Transplantation* 13(2):164-170, 1972.
- 4277 OESTROGEN PROFILES AND BREAST CANCER. (E.) Lipsett, M. B. (Natl. Inst. Child Hlth. Human Devel., Bethesda, Md.). *Lancet* 2(7738):1378, 1971.
- 4278 THE MORPHOLOGY OF ELASTOSIS IN THE REGION CLOSE TO KROMPECHER'S CARCINOMA. (Ger.) Kozlowski, H. (Inst. Path. Anat. Acad. Med. Gdansk, Poland), J. Kozakiewicz and W. Halgas. *Derm Mschr* 158(2):110-115, 1972.
- 4279 VEIN ENDOTHELIA DERIVED FROM TUMORS. (Ger.) Ito, K. (Surg. Clin. U. Tottori, Japan). *Yonago Acta Med* 15(2):86-98, 1971.
- 4280 A CASE OF TUMOR OF THE CAROTID BODY. (Ger.) Kato, D. (Surg. Clin. U. Tottori, Japan). *Yonago Acta Med* 15(2):81-85, 1971.
- 4281 AGE FACTORS INVOLVED IN THE MAMMARY GLAND CARCINOMA. (Ger.) Sekigawa, H. (Surg. Clin. U. Tottori, Japan). *Yonago Acta Med* 15(2):109-116, 1971.
- 4282 LYMPHOSARCOMATOSIS FOLLOWING CHRONIC LYMPHOCYTIC LEUKEMIA. (Ger.) Müller, D. (Med. Clin. U. Tübingen, Germany), W. Langer, W. Wilmanns, H. V. Gärtner and G. Schubert. *Blut* 24:12-22, 1972.
- 4283 MALIGNANT MELANOMA AND PIGMENTED (HAIRY) NEVUS. (Ger.) Krinitz, K. (Martin Luther U., Halle-Wittenberg, Germany) and A. K. Wozniak. *Derm Mschr* 158(2):130-139, 1972.
- 4284 PATHOLOGICAL ANATOMY OF MEDIASTINAL TUMORS. (Sp.) Bullon Ramirez, A. (Dept. Path. Anat. U. Med. Madrid, Spain), J. Sanz Esponera, A. Bullon Sopelana and J. Merchan Cifuentes. *Cir Espagn* 25(1):9-34, 1971.

- 85 THE MORPHOLOGY OF BRONCHIAL CARCINOMA. (Ger.) Lesch, R. (Inst. Path. U. eiburg, Germany). *Z Allgemeinmed* 47(32):1686-88, 1971.
- 86 OBSERVATIONS ON 276 ACUTE LEUKOSES: A CLINICAL AND STATISTICAL REVIEW. (Ger.) rtwich, G. (Med. Clin. U. Erlangen-Nürnberg, rmany) and W.-R. Weise. *Med Klin* 66(51):1758-64, 1971.
- 87 THE CILIOEPITHELIAL TUMOR CELLS. (Ger.) Kaltenbach, F. J. (Women's Clin. U. eiburg, Germany), M. Hilgarth and O. Fettig. *Gewebe Z Gynaek Geburtsh* 2(3):223-227, 1971.
- 88 A CASE OF ADENOMA OF THE THYROID WITH LUNG METASTASES: COMMENTS ON DIAGNOSIS AND THERAPY. (It.) Sala, L. (Civ. Hosp. Udine, Italy), Cattarossi, R. Zecchin and P. Collimedaglia. *Giuli Med* 25(6):353-367, 1970.
- 89 ON THE CO₂ FORMATION FROM C₁ METABOLISM OF ASCITES TUMOR CELLS. (Ger.) Thamm, R. (Inst. Physiol. Biol. Chem., Humboldt U. Berlin, rmany), S. Rapoport, and Ch. Hierardt-Hiebsch. *Acta Biol Med German* 27(3):459-476, 1971.
- 90 GIANT CELL LESIONS OF THE SKULL. (E.) Cares, H. L. (Massachusetts Gen. Hosp., ton) and L. Bakay. *Acta Neurochir* 25(1/2):1-18, 1971.
- 91 ODONTOGENIC TUMORS IN MAMMALS AND FISH. (E.) Gorlin, R. J. (U. Minnesota Sch. Dentistry, neapolis). *Oral Surg* 33(1):86-90, 1972.
- 92 MECHANISMS FOR CONTROL OF ACTH RELEASE IN PATIENTS WITH CUSHING'S SYNDROME ASSOCIATED WITH BRONCHIAL CARCINOID ADENOMAS. (Jap.) Nugent, C. (Nat'l. Hiromae Hosp., Japan), H. Tsuchida, K. Abe and E. Sato. *Igaku No Ayumi* 80(3):149-158, 1972.
- 93 A METASTASIZING T-1A SARCOMA. (Rus.) Kudryavtseva, G. T. (Acad. Med. Sci., R) and S. I. Kharlampovich. *Vop Onkol* 17(11):110-111, 1971.
- 94 CASE REPORT: ON PRIMARY DUODENAL CARCINOMA DEVELOPING FROM POLYPOSIS. (E.) Sievers, U. (Central Hosp., Singen, Germany). *Virchows Arch A Path Anat* 355(2):209-212, 1972.
- 4295 INSULIN SECRETING TUMOR OF THE PANCREAS WITH AMYLOID STROMA, WITH A CELL ADENOMAS: HISTOLOGICAL AND ULTRASTRUCTURAL STUDY. (Fr.) Roujeau, J. (Lariboisiere Hosp., Paris, France), J. Amouroux, A. Galian, Ch. Caulin, J. Gueris, R. Kalifat and P. Hautefeville. *Ann Anat Path (Paris)* 16(3):343-360, 1971.
- 4296 METASTATIC SPREADING OF LARYNX CANCER INTO REMOTE ORGANS. (Rus.) Sanzharovskaya, N. K. (Voroshilovgrad Med. Inst., USSR). *Zh Ushn Nos Gorl Bolez* 31(6):40-43, 1971.
- 4297 RELATIONSHIP OF ABO BLOOD GROUPS TO CERTAIN TYPES OF CANCER COMMON IN WESTERN INDIA. (E.) Jayant, K. (Cancer Res. Inst., Bombay, India). *Indian J Cancer* 185-188, 1971.
- 4298 STUDIES ON GLYCOLYTIC ENZYMES IN RELATION TO CANCER: PART III. CLINICAL SIGNIFICANCE OF SERUM PHOSPHOHEXOSE ISOMERASE AND ALDOLASE IN CANCER OF THE PROSTATE. A COMPARATIVE STUDY WITH SERUM ACID PHOSPHATASE AND SERUM ALKALINE PHOSPHATASE. (E.) Damle, S. R. (Cancer Res. Inst., Bombay, India), R. V. Talavdekar and T. B. Panse. *Indian J Cancer* 8(3):176-184, 1971.
- 4299 ULTRASTRUCTURE OF EWING'S SARCOMA OF THE BONE. (E.) Sirsat, S. M. (Cancer Res. Inst., Bombay, India), K. N. S. Panicker and G. G. Potdar. *Indian J Cancer* 8(3):157-162, 1971.
- 4300 FIBROUS DYSPLASIA OF BONE. (E.) Chitale, A. R. (J. J. Group Hosp., Bombay, India) and K. S. Masalawala. *Indian J Cancer* 8(3):147-156, 1971.

PREFACE

Carcinogenesis Abstracts is a publication of the National Cancer Institute. The journal serves as a vehicle through which current documentation of carcinogenesis research highlights are compiled, condensed, and disseminated on a regular basis. It represents an integral part of the Institute's program of fostering and supporting coordinated research into cancer etiology. Issues of *Carcinogenesis Abstracts* normally contain three-hundred-fifty abstracts and three-hundred-fifty citations (unaccompanied by corresponding abstracts). Abstracts and citations refer to the current scientific literature that describes the most significant carcinogenesis research carried on at the National Cancer Institute, other governmental agencies, and private institutions. *Carcinogenesis Abstracts* is intended to be a highly useful current awareness tool for scientists engaged in carcinogenesis research or related areas. The great number and diversity of publications relevant to carcinogenesis make imperative the availability of this service to investigators whose work requires that they keep abreast with current developments in the field.

Carcinogenesis Abstracts is normally published monthly. Volume X covers the scientific literature published from July 1971 through Dec 1972. A cumulative subject and author index for Volume X will be published shortly after the final regular issue. This journal is available free of charge to libraries and to individuals who have a professional interest in carcinogenesis. Requests for *Carcinogenesis Abstracts* from qualified individuals should include statements of their relationship to carcinogenesis research. All correspondence should be addressed as follows.

Carcinogenesis Abstracts

001 TRENDS IN LUNG CANCER: MORTALITY, INCIDENCE, DIAGNOSIS, TREATMENT, SMOKING, AND URBANIZATION. (E.) Schneiderman, M. A. (Nat'l. Cancer Inst., Bethesda, Md.) and D. L. Levin. *Cancer* 30(5):1320-1325, 1972.

International trends in male lung cancer mortality rates have been rising but are beginning to level off. In the U.S., rates for men follow international trends; rates for women are increasing at a greater than exponential pace and far more rapidly than for men. Rates for nonwhites are rising faster than for whites. The trends in smoking (as a measure of personal air pollution)-increasing for women, decreasing for men- and urbanization (as an indirect measure of nonpersonal air pollution)-higher for non-whites than for whites-are correlated with cancer trends. There is evidence that several lung cancer hazards operating together multiply the risks. Patterns in diagnosis and survival are discussed, and recommendations are made for future study and action to reduce lung cancer mortality. (14 references)

002 THE ENDOGENOUS FORMATION OF CARCINOGENIC N-NITROSO COMPOUNDS: IS THIS A POSSIBLE CAUSE OF HUMAN TUMORS? (Ger.) Osske, G. (Med. Acad. Erfurt, East Germany). *Arch Geschwulstforsch* 18(1):62-69, 1972.

in vitro and *in vivo* investigations of the endogenous formation of cancerogenic N-nitroso derivatives are summarized. The formation of these compounds is easily obtained from secondary amines, N-alkyl-N-arylamides in an acid medium following the addition of nitrogenated substances. It is suggested that such compounds may be formed in the intragastric medium. Among the nitrogenated substances, nitrates are the most important. In many countries these are found in food additives. Secondary amines may be present in human food, fermentation, alcohol and in tobacco. The experimental induction of malignant tumors in animals is reviewed. For prophylactic measures with respect to tumor formation in the intragastric region, it is recommended that the nitrogenated substances or the secondary amines be deleted from the diet. (36 references)

003 CURRENT OPINIONS ON THE ASBESTOS CANCER PROBLEM. (E.) Wagner, J. C. (Llandough Hosp., Penarth, Wales). *Ann Occup Hyg* 15:61-64, 1972.

Epidemiological data on the association of asbestos and cancer are reviewed. Excessive lung cancer incidence has been reported among asbestos miners in Australia, Rhodesia, Italy, Finland, and the Soviet Union. Excess lung cancer incidence has also been reported among asbestos-exposed insulation workers in New York and shipyard workers in Britain, Germany and Holland. Studies of the aerodynamics of various types of asbestos particles indicate that chrysotile fibers are unlikely to reach the pleura when inhaled;

this may explain the small mesothelioma risk attending chrysotile exposure. The different structure of crocidolite, the fiber which is associated with excess mesothelioma incidence, makes it more likely that these particles will be deposited in the pleura after inhalation. (22 references)

4304 EXTRAPOLATION OF EXPERIMENTAL CARCINOGENICITY TO THE REALITY OF INDUSTRIAL EXPOSURE.

(E.) Munn, A. (Imp. Chem. Ind. Ltd., Manchester, England). *Ann Occup Hyg* 15:75-79, 1972.

The relevance of experimental animal studies of chemical carcinogens for occupational safety is discussed. It is stressed that animal studies, in which large doses of chemicals are deliberately introduced by artificial routes, do not duplicate human industrial chemical exposures. At certain small dose levels, even potent carcinogens may not produce tumors; consequently, the finding that an agent is carcinogenic for animals at large doses does not mean it presents a danger for exposed humans. Moreover, a chemical compound (excluding skin carcinogen) cannot exert a carcinogenic effect until it is absorbed into the body. Thus, in assessing the supposed carcinogenic hazard of a chemical compound, as opposed to its actual carcinogenicity, factors influencing ease of absorption into the body must be considered. For example, chemicals which are carcinogenic by injection do not necessarily present a hazard for workers who are not exposed to them in that way. (13 references)

4305 ONCORNAVIRUSES AND THEIR PROVIRUSES. (E.) Bentvelzen, P. (Netherlands Cancer Inst., Amsterdam) and J. H. Daams. *Rev Europ Etud Clin Biol* 17(3):245-248, 1972.

The two prevailing theories of the "provirus", or viral agent supposed to give rise to neoplastic development in cells, are reviewed and a new hypothesis which reconciles the prevailing theories is presented. According to the "somatic provirus" theory, a virus infects a cell and proceeds to produce viral DNA by means of an RNA-dependent DNA polymerase. The viral DNA is integrated with host cell DNA which it alters to code for neoplastic conversion. According to the "germinal provirus" theory, the provirus genetic information is present in a host chromosome from the outset (no infection event is postulated) and is transmitted genetically to the offspring. No RNA-dependent DNA polymerase is required for virus continuity. Mutation, aging or carcinogenic stimuli cause the germinal provirus genetic information to be expressed, leading to cancer. In noncancerous cells, the germinal provirus is ordinarily repressed, possibly by some form of the classical repressor molecule. A new concept postulates that carcinogenic stimuli temporarily derepress a germinal provirus, which produces some viral RNA. This RNA produces a viral DNA by means of a reverse transcriptase (as in the somatic provirus) and this DNA becomes integrated into host cell DNA, but at a locus which is not affected by repressor molecules. Unsuppressed, the viral DNA

produces RNA which codes for neoplastic change. (26 references)

- 4306 ARE SOME HUMAN LYMPHOBLASTOID CELL LINES ESTABLISHED FROM LEUKEMIC TISSUES ACTUALLY DERIVED FROM NORMAL LEUKOCYTES? (E.) Belpomme, D. (Roswell Park Mem. Inst., Buffalo, N.Y.), J. Minowada and G. E. Moore. *Cancer* 30(1):282-287, 1972.

Data on properties of human lymphoid cell lines derived from leukemic tissues are reviewed and interpreted. In most cases it has been impossible to distinguish cell lines from leukemic donors from normal cell lines on the basis of cell morphology. The presence of herpes-like viruses does not provide a criterion of malignancy for cell lines, either, since these viruses have been reported in lines derived from normals. Cinematographic studies show that Burkitt lymphoma cells are relatively nonmotile, but do not allow the distinction of leukemic from normal cells. Among properties of malignant cells which approach the status of criteria for malignancy are abnormal chromosome constitution, high cloning efficiency in agar, successful heterotransplantability in immunosuppressed hosts and production of abnormal immunoglobulin. Nevertheless, similarities between normal and leukemic cell lines raise the question of whether supposedly malignant leukemic cell lines derived from leukemic blood are truly either malignant or leukemic. (67 references)

- 4307 AN ORIENTATION TO THE CONCEPT OF MINIMAL BREAST CANCER. (E.) Gallager, H. S. (U. Texas, M.D. Anderson Hosp. Tumor Inst., Houston) and J. E. Martin. *Cancer* 28(6):1505-1507, 1971.

The term "minimal breast cancer" is introduced to designate certain highly curable forms of mammary cancer. By definition it encompasses lobular carcinoma *in situ*, noninvasive intraductal carcinoma and invasive carcinoma, either lobular or ductal, forming a mass no greater than 0.5 cm in diameter. This formulation is a product of a study of breast carcinoma by subserial whole organ sectioning and mammography which led to the conclusion that breast carcinoma is not a focal process but a diffuse disease. Minimal breast cancer and early breast cancer are not coterminous designations. A lesion considered early breast cancer does not have the extremely favorable prognosis of noninvasive or microinvasive carcinoma. Similarly, minimal breast cancer must be distinguished from occult breast cancer as the occult category includes fully invasive, mass-forming lesions which are nonpalpable. The segregation of minimal breast cancer to a special category similar to that used for carcinoma *in situ* of the cervix would clarify end-result reporting and would lay the groundwork for therapeutic trials in this defined stage of carcinoma. The widespread use of mammography as a diagnostic tool has led to more frequent biopsy of small, suspicious lesions, and minimal breast cancer is thus being encountered more often. The need for accurate and simple

screening methods is discussed and techniques presently under development are mentioned with regard to their applicability. It is suggested that radical mastectomy is a more formidable procedure than that required for cure of minimal breast cancer. (8 references)

- 4308 OCCUPATIONAL MORTALITY: CANCER. (E.) Adelstein, A. M. (Office Population Census Survey, London, England). *Ann Occup Hyg* 15:53-57, 1972.

Cancer mortality in 27 occupations and in the occupations grouped according to social class is reviewed on the basis of data gathered by the British Census for 1961. Well-known occupational hazards, including skin, scrotal, bladder and nasal sinus cancers, are reconfirmed. Other findings include high rates of lip cancer in outdoor workers, high rates of stomach cancer in urban males, and high leukemia rates in farmers, fishermen, managers, artists and soldiers. Marked gradients of mortality are noted between social classes for cervix, lung and stomach cancer; these gradients are thought to reflect class-related differences in smoking, drinking and sexual behavior. (4 references)

- 4309 INTERNATIONAL CONFERENCE ON RNA VIRUSES AND HOST GENOME IN ONCOGENESIS. (E.) Bentvelzen, P. (Amsterdam, Holland). *Union Int Contre Cancer Bull* 9(2):2, 1972.

At the International Conference on RNA Viruses and Host Genome in Oncogenesis, held in Amsterdam from May 12-15, 1972, scientists from 19 countries presented their views on how interactions between viruses and host genes may lead to cancer. Several speakers indicated that susceptibility to an oncogenic virus is associated with membrane configuration which in turn might influence virus penetration or the chance for a membrane change leading to neoplasia. With regard to genetic transmission of oncornavirus, evidence was presented that all mice carry information for a mammary tumor virus. One speaker postulated that a genetically transmitted oncornavirus is switched on during embryogenesis, switched off during normal adult life and switched on during carcinogenesis. Another theory advanced holds that only a partial provirus is present initially in the germline; new tumor viruses may originate due to duplication of polymerase, somatic mutation and recombination. Results of a panel discussion suggested that no RNA-instructed DNA polymerase is needed for continuity of germinal proviruses. The enzyme is apparently necessary only for the establishment of a new somatic provirus at a site where no repression of transcription takes place. (No references)

- 4310 INTERCELLULAR JUNCTIONS IN NORMAL AND IN MALIGNANT CELLS. (E.) Martinez-Palomo, A. (No affiliation). *Pathol Annu* 1(1):261-279, 1971.

studies pertaining to altered contact properties in malignant cells are reviewed. Electrophysiologic techniques have shown that epithelial and mesenchymal tissues have a form of intercellular communication determined by the free passage of ions from cell to cell through contact regions of low resistance. Under normal conditions, gap junctions and, probably, tight junctions represent the structural basis for this form of electrical communication. Gap junctions appear to function as highly permeable regions of intimate membrane apposition. Tight junctions may contribute to electrical coupling, acting as high resistance barriers that isolate the extracellular space and thus facilitating the flow of ions through the more permeable membrane regions. Most malignant epithelial cells lack electrical coupling. In differentiated carcinomas, desmosomes and gap junctions are decreased in number, while tight junctions become permeable to electron-dense tracers. No intercellular junctions are present in highly anaplastic tumors of epithelial origin. Mesenchymal tumor cells show normal electrical communication but lack tight and gap junctions. It is likely that the abnormal surface connections of malignant cells revealed by electrophysiologic and ultrastructural methods have considerable significance in relation to the establishment of malignant growth. 311 MOLECULAR HYBRIDIZATION: A POWERFUL APPROACH TO THE DETECTION OF VIRAL NUCLEIC ACID SEQUENCES IN HUMAN CANCER. (E.) Green, M. (Saint Louis U. Sch. Med., Missouri) and H. J. Raskas. *J Nat Cancer Inst* 48(6):1559-1565, 1972.

The applications of molecular hybridization to the detection and quantitation of viral nucleic acids in productively infected and transformed cells are reviewed. Detection of DNA tumor virus genetic information in human cancers by molecular hybridization has been attempted by three methods. Virus-specific RNA in DNA tumor virus-transformed cells can be detected by DNA-RNA hybridization; the precision of this method is stressed. In addition, RNA polymerase from *E. coli* can be used to synthesize highly radioactive and virus-specific RNA which can be annealed with DNA from cells. A third method is molecular hybridization competition analysis, which is based on the premise that viral RNA sequences, present in RNA from human cancers, will block the annealing of virus-specific RNA to viral DNA. Data from molecular hybridization analyses of human cancers for RNA tumor-virus genetic information are reviewed. Examples of positive hybridization of human ovarian cancers and murine sarcoma virus DNA are discussed. (27 references)

312 CLINICAL, EPIDEMIOLOGIC, AND PATHOLOGIC FEATURES OF CYTOTOXIC AND ONCOGENIC HERPESVIRUS IN SOUTH AMERICAN MONKEYS. (E.)

Hunt, R. D. (Harvard Med. Sch., Southboro, Mass.) and L. V. Melendez. *J Nat Cancer Inst* 49(1):261-271, 1972.

Properties of herpesviruses which are cytotoxic or oncogenic for South American monkeys species are reviewed. Three herpes viruses produce cytotoxic infections in some monkeys: *Herpesvirus T*, *H. simplex* and spider monkey herpesvirus (*H. ateles* type 1). Hosts for infections with these viruses are either not susceptible, susceptible but not fatally so, or fatally affected. The basis for these differences in susceptibility in monkeys is probably genetic, but details are unclear. Characteristic pathogenic changes in susceptible monkeys infected with cytotoxic herpesviruses include development of intranuclear inclusions, development of multinucleated giant cells and degenerative changes leading to cell death or lysis. The oncogenic herpesviruses discussed are *H. saimiri*, which causes malignant lymphoma, and *H. ateles*, which is associated with malignant lymphoma and leukemia in spider monkeys. (43 references)

4313 AETIOLOGICAL FACTORS IN SQUAMOUS CELL SKIN CANCER. (E.) Swanbeck, G. (Karolinska Inst., Stockholm, Sweden). *Brit J Derm* 85(4):394-396, 1971.

External factors operative in producing squamous cell skin cancer (SCSC) are reviewed. Frequency of occurrence of SCSC is highest on the external ear, face, scalp, neck, genitals and hands of men and the legs of women. The nearly tenfold higher incidence of SCSC on the external ear of men compared with women indicates the etiologic importance of the sun-radiation factor. Geographic frequency of occurrence at specific sites on the body shows higher frequency of occurrence on head, hands, and lower limbs in residents of southern Sweden than residents of northern Sweden. Doubling of SCSC incidence rate among white people for each 3° 48' south in latitude in the northern hemisphere is a striking illustration of the cancer-promoting properties of solar radiation. Dimer formation between thymidine radicals in DNA by UV light and the mutation effect on DNA during replication are discussed. Experimental chemical induction of SCSC by coal-tar derivatives is reviewed in light of the widespread use of this material in the treatment of psoriasis and eczema. The frequency of SCSC occurrence following burn or mechanical injury suggests that epidermal atrophy is a predisposing factor. The cellular kinetics in epidermis is another important factor, since it may influence the carcinogenicity of other carcinogenic factors. (20 references)

4314 THE PROTOPLASMIC PATTERNS OF TISSUES AND TUMORS. (E.) Knox, W. E. (Harvard Med. Sch., Boston, Mass.). *Amer Sci* 60(4):480-488, 1972.

The application of tissue composition analysis to the understanding of neoplastic development is reviewed.

Various procedures have been used to itemize the kinds and amounts of the biochemical and especially the enzymatic components of different tissue systems. Comparison of normal and neoplastic tissue on this molecular level suggests that tumors resemble each other more than they resemble the normal tissue from which they arise. The diversity seen among tumors is confined to well-differentiated tumors; anaplastic tumors of various origins are similar. Tissue analysis of fetal tissue indicates that there is an analogy between the progressive differentiation of fetal tissue and the reverse of the process, i.e., loss of differentiation, in tumor cells. It appears that the same enzymes change in fetal and in neoplastic tissues. (16 references)

- 4315 THE SV40 GENOME IN TRANSFORMED MAMMALIAN CELLS. (Pol.) Steplewski, Z. (Inst. Oncol., Gliwice, Poland). *Postepy Hig Med Dosw* 25(4):571-612, 1971.

The state of the art of research into the SV40 virus genome in transformed mammalian cells is reviewed. Discussions on viral multiplication, cell transformation and subsequent hybridization are included. Activation of infectious SV40 in heterokaryocytes, detection of T-antigen by immunofluorescence and internuclear transfer are reviewed. Techniques for isolation of infectious SV40 and for infection of cell hybrids are described. The possibility of SV40 genome activation in transformed cells is noted. This activation may be accomplished by means of cell fusion with SV40-susceptible monkey kidney cells. Where the virus genome is defective, double fusion techniques permit recombination as well as activation of the virus. (103 references)

- 4316 BIOENERGETICS AND THE PROBLEM OF TUMOR GROWTH. (E.) Racker, E. (Dept. Biochem, Cornell U., Ithaca, N.Y.). *Amer Sci* 60(1):56-63, 1972.

The current status of research on the mechanisms initiating and controlling biological energy and their relationship to tumor growth is reviewed. Energy formation in cells by the two pathways of glycolysis and oxidative phosphorylation is discussed. Of the two major hypotheses of oxidative phosphorylation, the chemical hypothesis involves three high-energy intermediates: 1) a nonphosphorylated intermediate of the oxidation chain ($A \sim X$) which arises by oxidation of the substrate ($A_{reduced}$); 2) a second nonphosphorylated intermediate without a respiratory component; and, 3) a third phosphorylated intermediate ($X \sim P$). The chemiosmotic hypothesis has as its key feature translocation of protons from one side of the membrane to the other, which takes place during mitochondrial oxidation of substrates. Fundamentally, the difference between the two hypotheses lies in the steps leading to $X \sim Y$ formation. Experimental evidence supporting one or the other of these hypotheses does not as yet permit an

objective decision in either direction. The numerous investigative efforts to determine the role of phospholipids in oxidative phosphorylation are reported. It is proposed that a multitude of primary lesions induced by virus, carcinogens or mutations have in common the ability to cause persistent alteration in the intracellular pH (and perhaps temperature), and thereby upset the normal regulating mechanisms that prevent uncontrolled growth. Further, it is proposed that tumors can be caused by these disturbances in regulatory action. (49 references)

- 4317 CHROMOSOME ABNORMALITIES AND CARCINOGENESIS. (E.) Pogosianz, H. E. (Acad. Med. Sci., Moscow, USSR) and E. L. Prigogina. *Neoplasma* 19(4): 319-325, 1972.

Laboratory studies of the role of chromosome aberration in carcinogenesis are summarized. Mutagenic and carcinogenic effects in mammalian cells of chemical carcinogens, including hydroxyurethane and methyl nitrosourea, were investigated. Karyotype analyses of human tumors and of tumors of the Hungarian hamster were also performed. In the course of these studies, a correlation was noted between high ploidy and lack of morphological differentiation in human seminomas. The incidence of inborn chromosome aberrations in hematopoietic cancer patients is under continuing investigation. Taken together, these studies suggest that chromosome mutations in tumors represent a secondary phenomenon. (32 references)

- 4318 PART VII. CANCER AND INFECTIOUS DISEASES RELATED TO GEOCHEMICAL ENVIRONMENT. IS THERE A PARTICULAR KIND OF SOIL OR GEOLOGIC ENVIRONMENT THAT PREDISPOSES TO CANCER? (E.) Armstrong, R. W. (Sch. Pub. Hlth., U. Hawaii, Honolulu). *Ann NY Acad Sci* 199: 239-248, 1972.

Research on correlations between soil composition and cancer occurrence is reviewed. In France, high mortality from all cancer types is reportedly associated with magnesium-poor soils. Soil drainage conditions and organic matter contents have been linked to cancer in Welsh studies. In the Netherlands, cancer frequency is high in areas with peat soils. Studies of migrant populations suggest that variations in cancer mortality are likely to be due to local differences in environment rather than to the genetic makeup of the populations. The association between soil composition and cancer is probably mediated by the food chain. However, the extreme complexity of the relationships between soil composition, food chain, and cancer is emphasized. (59 references)

- 4319 SOME CLINICAL ASPECTS OF THE PARA-ENDOCRINE SYNDROMES. (E.) Ross, E. J. (U. College Hosp. Med. Sch., London, England). *Proc Roy Soc Med* 65:59-60, 1972.

The significance of hormone secretion by human cancer cells is discussed. Among the polypeptide hormones produced by cancers of various sites are corticotrophin, vasopressin, gonadotrophin, erythropoietin and insulin. It appears that copious secretion of cortisol in ACTH-secreting tumors hastens metastatic spread and shortens survival of bronchial oat-cell carcinoma patients. Investigations of adrenocortical activity in cancer patients has shown a raised plasma cortisol concentration. However, it is apparently not the case that most tumors secrete corticotrophin. Rather, tumors may secrete a corticotrophin-releasing factor which acts through the patients' pituitaries. (2 references)

- 4320 BURKITT'S LYMPHOMA AND *HERPESVIRUS SAIMIRI* LYMPHOMA: COMPARATIVE ASPECTS. (E.) Epstein, M. A. (U. Bristol Med. Sch., England). *J Nat Cancer Inst* 49(1):213-217, 1972.

Herpesvirus saimiri lymphoma development in an animal model may provide information relevant to the etiology and study of Burkitt's lymphoma in man. There are several differences, however, between *H. saimiri* lymphoma and Burkitt's lymphoma. *H. saimiri* lymphoma does not occur under natural conditions as does Burkitt's lymphoma. *H. saimiri* is apparently nonpathogenic for its natural host, the squirrel monkey; it causes malignant tumors only when inoculated into such animals as owl monkeys or marmosets. Unlike Burkitt's lymphoma, which is usually well-differentiated and which involves bizarre sites and rarely invades peripheral lymph nodes, *H. saimiri* lymphoma consists of a marked, widespread reticulum cell invasion of many organs, especially the liver, kidney, spleen, lymph nodes and adrenals. *H. saimiri* and Epstein-Barr (EB) virus, the presumed etiological agent of Burkitt's lymphoma, also differ in their patterns of cell transformation *in vitro*. Unlike *H. saimiri*, EB virus does not infect a wide range of monolayer test tissue cultures. Although the EB viral genome is present in all cells of an infected culture, only a relatively small proportion of these cells replicate virus, resulting in cell lysis and death. In contrast, virus production by lysis is fairly widespread in *H. saimiri*-infected cultures. New methods have enabled the infection of human embryo cells with EB virus. The cells become transformed but do not produce virus. Despite these differences, if *H. saimiri* can be made to induce lymphoma in its natural host, perhaps in association with some environmental co-factor as has been implicated with Burkitt's lymphoma, its study may provide information pertinent to the etiology of Burkitt's lymphoma. - 4321 RECENT ADVANCES IN NEUROBLASTOMA. (E.) Finkelstein, J. Z. (Harbor Gen. Hosp., Los Angeles, Calif.) and G. S. Gilchrist. *California Med* 116(3):27-36, 1972.

Advances in research on the pathophysiology of neuro-

blastoma are reviewed. Neuroblastoma, one of the more common infantile tumors, shows wide histopathological variation from tumor to tumor and even within the same tumor; cells may be undifferentiated and sarcoma-like, or fully mature. A unique clinical feature of neuroblastoma is its high rate of spontaneous regression during the first year of life. Neuroblastoma also shows a tendency to mature to the more benign ganglioneuroma. Maturation to the more benign form may be mediated by a serum factor, a protein which apparently works to stimulate RNA synthesis. The association of neuroblastoma with neurofibromatosis (von Recklinghausen's disease) is described, and treatment of neuroblastoma is discussed. (56 references)

- 4361 HISTOPATHOLOGIC STUDIES ON EFFECTS OF HYPOPHYSECTOMY ON EXPERIMENTAL HEPATOCARCINOGENESIS IN RATS. (Jap.) Yokota, Y. (Nara Med. U., Japan). *J Nara Med Ass* 22(213):192-205, 1971.

Intact and hypophysectomized male rats were fed a diet containing 3'-methyl-4-dimethylaminoazobenzene (3'-Me-DAB), 2-fluorenylacetaide (2-FAA) or ethiomine for eight months. Hypophysectomized rats given 3'-Me-DAB or 2-FAA did not develop liver cancer, but hypophysectomized rats given ethiomine developed liver cancer or nodular hypertrophy. Liver cancers were induced in rats hypophysectomized after feeding with 3'-Me-DAB for three months but not in rats hypophysectomized after feeding with 2-FAA for three months. The effect of hypophysectomy following an ethiomine diet was not clear. Hydrocortisone significantly increased the activity of tryptophan pyrrolase in the livers of hypophysectomized rats fed 3'-Me-DAB. It did not increase liver tryptophan pyrrolase activity in hypophysectomized rats fed ethiomine or in intact rats. Hypophysectomy seemed to have varied effects on artificial growth of liver cancer due to differences of metabolic mechanisms of the various carcinogens. Pituitary hormone appeared to have a definite influence on the transition of a nodular growth into a cancerous growth, but had no clear influence on cancer growth itself.

- 4362 VITAMIN A-INDUCED MODIFICATION OF BENZO[a]PYRENE METABOLISM IN SYRIAN HAMSTER CELL CULTURES. (E.) Rasmussen, R. E. (U. California, Sch. Med., San Francisco), I. Y. Wang and T. T. Crocker. *J Nat Cancer Inst* 49(3):693-700, 1972.

With repeated passage, cultures of Syrian hamster embryo cells lost both the ability to convert benzo[a]pyrene (BP) to metabolic products and to bind BP to cellular components. Treatment of such late-passage cells with vitamin A, at levels of 1 µg/ml or less, restored their BP metabolizing activity. This effect was not immediate but required at least two days of exposure to vitamin A, suggesting that extensive subcellular changes were occurring. The restoration of BP metabolizing activity was observed as increased binding of ³H-BP to cell components as well as an increase in specific enzymatic activity of cell-free preparations from vitamin A-treated cells.

- 4363 CHEMICAL CARCINOGENESIS AND HUMORAL ANTIBODY SYNTHESIS. (E.) Brai, M. (Pub. Hlth. Res. Inst., New York, N.Y.), A. Patrucco and A. G. Osler. *J Immun* 109(2):317-323, 1972.

Swiss Webster mice were injected s.c. with 0.2 ml 3-methylcholanthrene (3-MCA) given alone or three days before or after antigenic stimulation by i.p. injection of sheep erythrocytes (SRBC) or human serum albumin (HSA). The effect of 3-MCA on primary and secondary humoral immune responses to the antigens was observed by hemolytic antibody

titrations. 3-MCA failed to suppress anti-SRBC or anti-HSA antibody titers; though all mice given 3-MCA developed tumors, antibody titers were similar in 3-MCA-treated and untreated mice. 3-MCA did not diminish secondary immune antibody responses, which were monitored after booster injections of antigen. At the time of sacrifice, the weight of each mouse and its extirpated spleen was recorded for calculation of the spleen index. The elevated indices in the tumor-bearing animals were believed the result of decreased body weight and toxic splenomegaly associated with the presence of the tumor.

- 4364 AM AUTORADIOGRAPHIC STUDY OF THE EARLY EFFECTS OF 7,12-DIMETHYLBENZ(a)ANTHRACENE AND PROGESTERONE ON DNA SYNTHESIS IN RAT MAMMARY EPITHELIAL CELLS AND SUBSEQUENT TUMOUR DEVELOPMENT. (E.) Jabara, A. G. (Dept. Path. Statistics, U. Melbourne, Australia), P. H. Toyne and R. J. Fisher. *Brit J Cancer* 26(4):265-273, 1972.

Experiments were undertaken to determine (1) the early effects of dimethylbenz(a)anthracene (DMBA) or progesterone, or the two in combination, on DNA synthesis in adult female Sprague-Dawley rat mammary epithelial cells and (2) whether there was any correlation between the extent of DNA synthesis observed in the first 96 hr after administration of the drugs and subsequent tumor development. Animals received daily s.c. injections of 3 mg progesterone for 25 or two days prior to receiving a single dose of 30 mg DMBA by gastric intubation. Treated rats were injected i.p. with ³H-thymidine. Two hr later, mammary glands were removed and the number of cells which incorporated label was determined by autoradiography. Administration of DMBA alone caused an insignificant reduction in DNA synthesis below control levels in the first 96 hr, whereas progesterone significantly increased DNA synthesis. Administration of progesterone plus DMBA resulted in an increase in DNA synthesis above both control and DMBA values but less than that produced by progesterone alone. A two-way analysis of variance revealed no interaction between DMBA and progesterone in relation to mammary epithelial cell DNA synthesis. Mammary carcinomas (and one adenoma) occurred only in rats which received DMBA with or without progesterone. No correlation was found between the extent of DNA synthesis observed in mammary glands biopsied between six and 96 hr after DMBA administration and the occurrence of tumors in the host rats 135 days later.

- 4365 CARCINOGENICITY OF DERIVATIVES OF 7,12-DIMETHYLBENZ(a)ANTHRACENE. (E.) Flesher, J. W. (U. Kentucky Coll. Med., Lexington) and K. L. Sydnor. *Cancer Res* 31:1951-1954, 1971.

Eleven derivatives of 7,12-dimethylbenz(a)anthracene (DMBA) were tested for carcinogenicity in Sprague-Dawley female rats by the s.c. injection of 1.0 or 0.1 mg of compound dissolved in 0.1 ml of sesame oil on alternate days for 20 doses. Eight derivatives [7-hydroxymethyl-12-methyl-7-formyl-12-methyl-, 7-

methoxymethyl-12-methyl-7-acetoxymethyl-12-methyl-, 7-benzoyloxymethyl-12-methyl-, 7-iodomethyl-12-methyl-, 7-bromomethyl-12-methyl-, and 7-chloromethyl-12-methylbenz(a)anthracene] were carcinogenic at the 1-mg dose level, and 5 [benzoyloxymethyl-12-methyl-, 7-formyl-12-methyl-, 7-bromomethyl-12-methyl-, 7-hydroxymethyl-12-methyl-, and 7-iodomethyl-12-methylbenz(a)anthracene] were carcinogenic at the 0.1-mg dose level (200 days of observation). All compounds which were carcinogenic were ones which would be expected to be converted to 7-hydroxy-DMBA *in vivo*. These results indicate that metabolic activation of DMBA is necessary for activity. They are also consistent with the hypothesis that the ultimate carcinogen of polycyclic hydrocarbons is a carbonium ion. It is proposed that DMBA is hydroxylated to 7-hydroxy-DMBA, which is then converted to a derivative (e.g., a sulfate ester) that would be expected to be a good leaving group and which would generate a highly reactive carbonium ion. The carbonium ion could then react with critical nucleophiles to initiate the chain of cellular events which result in cancer.

4366 CARCINOGENICITY OF ORGANIC FRACTIONS OF PARTICULATE POLLUTANTS COLLECTED IN NEW YORK CITY AND ADMINISTERED SUBCUTANEOUSLY TO INFANT MICE. (E.) Asahima, S. (Case Western Reserve U. Sch. Med., Cleveland, Ohio), J. Andrea, A. Carmel, E. Arnold, Y. Bishop, S. Joshi, D. Coffin and S. S. Epstein. *Cancer Res* 32(10):2263-2268, 1972.

Groups of randomly bred infant Swiss mice were given s.c. injections of suspensions of (a) an organic extract of particulate atmospheric pollutants collected in New York City; (b) derived acidic, basic, neutral, aliphatic, aromatic, and insoluble fractions; and (c) three oxyneutral subfractions, in total doses of 10, 20, and 40 mg. Each test group consisted of a minimum of 44 mice; concurrent controls were comprised of 81 untreated and 86 solvent-treated mice. There were wide variations in the overall carcinogenicity and incidence of tumors in various organs in different test groups. High incidences of hepatomas were found in males given injections of the basic fraction and to a lesser extent in males and females given injections of the organic extract. The incidence of lymphomas was high, particularly in females given injections of basic, aliphatic, and aromatic fractions and oxyneutral subfractions. Additionally, high incidences of solitary and multiple pulmonary adenomas were found in mice given injections of basic, neutral, and aromatic fractions and oxyneutral subfractions. Coexistent multiple tumors were also found in mice given injections of basic and aromatic fractions and oxyneutral subfractions. Injection site tumors were rare.

4367 EARLY EFFECTS OF 12-O-TETRADECANOYL-PHORBOL-13-ACETATE ON THE INCORPORATION OF TRITIATED PRECURSOR INTO DNA AND THE THICKNESS OF THE INTERFOLLICULAR EPIDERMIS, AND THEIR RELATION TO TUMOR PROMOTION IN MOUSE SKIN. (E.) Raick, A. N.

(Dept. Path., U. Toronto, Ontario, Canada), K. Thumm and B. R. Chivers. *Cancer Res* 32:1563-1568, 1972.

Female Swiss Webster ICR mice were treated with 0.0016-0.16 μ moles 12-O-tetradecanoyl-phorbol-13-acetate (TPA). Extensive skin ulceration resulted in mice given 0.16 μ mole TPA and some ulceration was caused by 0.016 μ mole. Mice given 0.00016-0.016 μ mole TPA after application of TPA or 7,12-dimethylbenz(a)anthracene had markedly thickened interfollicular epidermis (IFE). The increase in IFE thickening and the rate of thickening were correlated with TPA dose. A second dose of TPA (0.016 μ mole) one week after the initial 0.016 μ mole dose induced 1.5-2 times the IFE thickening induced by a single TPA dose. A single application of TPA (0.00016-0.16 μ mole) initially inhibited the uptake of thymidine-methyl- 3 H into mouse skin DNA; however, a marked stimulation of precursor uptake followed this inhibition. Precursor uptake by skin DNA returned to control levels thereafter. The degree of stimulation of precursor uptake by DNA correlated well with TPA dose up to 0.016 μ moles; no further increase in precursor uptake was associated with increasing TPA dose beyond this point. There was a correlation between increased IFE thickness and skin tumor promotion with 0.016 and 0.0016 μ mole TPA. However, 0.00016 μ mole induced a significant increase in IFE thickness and in precursor uptake by skin DNA but did not show tumor promoting activity.

4368 THE INHIBITION OF CROTON OIL-PROMOTED MOUSE SKIN TUMORIGENESIS BY STEROID HORMONES. (E.) Belman, S. (New York U. Med. Ctr., N.Y.) and W. Troll. *Cancer Res* 32(3):450-454, 1972.

The tumor-inhibiting effects of steroid hormones were studied and compared with steroid antiinflammatory and antimitotic activities. Tumors were induced on the backs of female Swiss Millerton mice with 25 μ g 7,12-dimethylbenz(a)anthracene. Two weeks later tumorigenesis was promoted by applying 0.2 ml of 0.5% croton oil in acetone three times a week. Steroids were applied to the same areas at 6 and 30 μ g (in acetone) concentrations five times a week starting at the time croton oil was applied. Each steroid was tested on 24 mice. Tumor inhibition was dose dependent in the order dexamethasone > Schering No. 11572 > prednisolone > hydrocortisone > cortisone. Antiinflammatory effects of the steroids was tested by applying a mixture of croton oil, acetone solvent and one of the test hormones to the right ear of mice and swabbing the left ear with solvent alone. Four hr following treatment the ears were cut off and weighed, then dried and reweighed. The order of antiinflammatory activity was Schering No. 11572 > dexamethasone = prednisolone > hydrocortisone > cortisone = control. In a third series of tests the mitotic activity of epidermal cells was observed. Croton oil and steroid in acetone solvent were applied to the dorsal skin of mice. Twenty-four hr later, colchicine was injected i.p. The animals were sacrificed 4 hr later and skin sections were prepared for histological examination. Findings

in this series indicated that cortisone acted as a stimulus and increased the mitotic rate. Hydrocortisone and prednisolone inhibited mitosis but only at high doses, while dexamethasone and the Schering compound inhibited mitosis at all concentrations tested.

- 4369 INFLUENCE OF SOME NITROFURANS ON CARCINOGENESIS IN RATS FED 4-(DIMETHYLAMINO)-AZOBENZENE. (E.) Akao, M. (Inst. Food Microbiol., Chiba U., Japan), K. Kuroda, M. Kanisawa and K. Miyaki. *Gann* 62:479-484, 1971.

Four nitrofurans were compared for their effect on carcinogenesis induced by 4-(dimethylamino)azobenzene (DAB). The nitrofurans tested were 2-(2-furyl)-3-(5-nitro-2-furyl)acrylamide (N1), 2-amino-5-[2-(5-nitro-2-furyl)-1-(2-furyl)-vinyl-1]-1,3,4-oxadiazole (N2), 5-nitro-2-furaldehyde semicarbazone (N3), and 5-morpholinomethyl-3-(5-nitrofurfurylideneamino)-2-oxazolidone (N4). Male Donryu rats were maintained on a diet containing 0.06% DAB and 0.2% of a nitro-furan until they consumed 1 g of DAB (about 3.5 months), and succeeding on a basal diet for one month. The liver of these animals was compared histopathologically with those of the animals fed a diet containing DAB alone. The induction of histopathological changes in the liver due to the administration of DAB was almost completely inhibited by the concurrent administration of N1 or N2. A similar activity was noted in N3, but the activity was moderate, and hyperplasia of small bile ducts and regenerative cell nodules were seen in the liver of the animals fed DAB and N3. No such inhibitory activity was found in N4, and typical trabecular hepatoma, cholangiofibrosis and atypical cell growths were seen in the animals fed DAB and N4. The liver enzyme activity of metabolizing azo dye was not significantly changed by 3.5-months' administration of any of the nitrofurans. The effect of nitrofurans on the levels of free and protein-bound dyes in the liver was more important for the mode of their action in inhibiting DAB carcinogenesis. However, it was noted that N2 and N3, both of which inhibited DAB carcinogenesis, showed no significant activity to reduce the protein-bound dye level.

- 4370 CARCINOGENESIS WITH 3-METHYLCHOLANTHRENE IN UTRINE CERVIX OF MICE TREATED NEONATALLY WITH ESTROGEN. (E.) Forsberg, J.-G. (Inst. Anat., U. Bergen, Norway) and L. S. Breistein. *J Nat Cancer Inst* 49(1):155-172, 1972.

Virgin female NMRI mice were given s.c. injections of 5 µg estradiol-17β beginning on the day of birth and continuing for five days thereafter. Some hormone-treated mice had beeswax or beeswax-and-3-methylcholanthrene (MCA)-impregnated threads implanted in the uterine cervix. In mice given estradiol but no thread, a columnar epithelium with an abnormally wide extension developed in the cervical canal. The MCA-treated thread produced an irritation which in turn caused rapid

epidermization in the cervical canal. Columnar epithelium in these mice was replaced by squamous epithelium in the common cervical canal. In some cases, squamous epithelium grew under columnar epithelium, the latter tissues eventually being shed. The initial incidence of invasive lesions caused by the MCA-treated thread might have been influenced by epidermization and a changed gonadotropin pattern. The persistent production of ovarian estrogen in estradiol-treated mice apparently retarded the growth of lesions.

- 4371 C-TYPE PARTICLES IN PRIMARY AND TRANSPLANTED LUNG TUMORS INDUCED IN BALB/c MICE BY HYDRAZINE SULFATE: ELECTRON MICROSCOPIC AND IMMUNODIFFUSION STUDIES. (E.) Bucciarelli, E. (Perugia U. Med. Sch., Italy) and R. Ribacchi. *J Nat Cancer Inst* 49(3):673-684, 1972.

Primary lung tumors induced in BALB/c mice by hydrazine sulfate, transplants of these tumors in newborn and adult syngeneic hosts taken between the first and twenty-fourth transplant generations, and samples of normal tissue from tumor-bearing mice were studied in the electron microscope for the presence of virus particles. Immunodiffusion studies for the presence of type-C, group-specific viral antigens were done on both transplanted tumors and normal tissues of the same mice. The neoplastic cells of the primary and transplanted tumors retained the typical structure of the cell of origin, the type-B alveolar cell. Cylindrical, type-C, and intracisternal A virus particles were observed. Cylindrical particles were seen only in the primary tumors and, characteristically, originated from dark, granular, cyst-like areas of the neoplastic cells. C particles budded from the neoplastic cells or in intercellular spaces in 35% of primary tumors, 62.5% of transplanted tumors in newborn mice, and 31% of those transplanted into adults. Intracisternal A particles were seen in the neoplastic cells of 88% of the primary tumors, 25% of the tumors transplanted into newborns, and in 12.5% of those grafted into adults. In 63.6% of the normal lung-tissue samples, only intracisternal A particles were observed. Type-C, group-specific viral antigens were demonstrated by immunodiffusion in the transplanted tumors but not in the normal organs of tumor-bearing mice. These data suggest a possible activation of type-C virus particles in type-B alveolar cells by a chemical carcinogen.

- 4372 EFFECT OF UNILATERAL URETER LIGATION ON DEVELOPMENT OF TUMORS IN THE URINARY SYSTEM OF RATS TREATED WITH N-BUTYL-N-(4-HYDROXYBUTYL)-NITROSOAMINE. (E.) Ito, N. (Nara Med. U., Japan), S. Makiura, Y. Yokota, Y. Kamamoto, Y. Hiasa and S. Sugihara. *Gann* 62(5):359-365, 1971.

The effect of unilateral ureter ligation on the development of tumors in the renal pelvis, ureter, and urinary bladder of male Wistar strain rats treated with N-butyl-N-(4-hydroxybutyl)nitrosoamine was investigated. The activities of β-glucuronidase

in homogenates of liver, kidney, and bladder of rats after unilateral ureter ligation were also examined. The incidence of kidney and ureter tumors in rats treated with N-butyl-N-(4-hydroxybutyl)nitrosamine was much higher after ligation of one ureter. The present results showed that unilateral ligation of the ureter was a good method to induce transitional cell carcinomas in the kidney and ureter of rats treated with N-butyl-N-(4-hydroxybutyl)nitrosamine. Hyperplasia of the epithelium of the renal pelvis and ureter was occasionally seen in carcinogen-treated rats. It was suggested that the hyperplastic changes were precursors of transitional cell carcinoma of the renal pelvis and ureter in rats receiving N-butyl-N-(4-hydroxybutyl)nitrosamine. The activity of β -glucuronidase was raised in tumors of the urinary bladder but the activity of this enzyme in liver and kidney tissues was not influenced by the administration of N-butyl-N-(4-hydroxybutyl)nitrosamine.

4373 ACCUMULATION OF ^3H -ESTRADIOL IN TESTES AND PITUITARY GLANDS OF MICE OF STRAINS DIFFERING IN SUSCEPTIBILITY TO TESTICULAR INTERSTITIAL CELL AND PITUITARY TUMORS AFTER PROLONGED ESTROGEN TREATMENT. (E.) Bollengier, W. E. (Yale U. Sch. Med., New Haven, Conn.), A. J. Eisenfeld and W. U. Gardner. *J Nat Cancer Inst* 49(3):847-852, 1972.

Male mice from four different inbred strains differed in susceptibility to testicular interstitial cell tumors (ict) (susceptible A and BALB/c strains) and pituitary tumors (susceptible C57 strain) after prolonged exposure to estrogens. Tritiated estradiol (^3H -E2) was administered to determine possible strain differences in estradiol localization in testes and pituitary glands. The testes of mice of all strains retained more ^3H -E2 at 1 hr after injection than did plasma or fat, but showed no consistent differences distinguishing mice from strains susceptible to ict. The testes retained much less radioactivity 4 hr after injection and did not show a lower accumulation of radioactivity when ^3H -E2 was given 1 hr after a high dose of diethylstilbestrol. The accumulation in the testes was highly variable between experiments, and other experimental approaches are believed necessary to study estrogen interaction with the interstitial cell. The pituitary glands of all strains had high levels of radioactivity at 1 and 4 hr. Pituitary ^3H -E2 accumulation was reduced after previous treatment with diethylstilbestrol. Chromatographic estimation of the extracted free estrogen from testes and pituitary glands of mice of all 4 strains showed approximately 90% in the estradiol fraction and about equal amounts in the estriol and estrone fractions. Strain differences in pituitary radioactivity could not be associated with the tendency toward pituitary tumors.

4374 EFFECTS OF AFLATOXINS ON NUCLEIC ACID AND NUCLEAR PROTEIN SYNTHESIS IN ISOLATED PERFUSED REGENERATING RAT LIVER. (E.) Gerber, G. B. (Euratom Radiobiol. Dept., C.E.N./S.C.K., Mol,

Belgium). *Environ Physiol* 1(2):55-60, 1972.

The action of aflatoxin B_1 on synthesis of DNA and nuclear proteins was studied in isolated regenerating rat liver perfused 24 hr after partial hepatectomy with a mixture of heparinized rat blood, Ringers solution, and glucose (total volume, 40 ml). Following equilibration, 0, 100, or 500 μg aflatoxin B_1 in 0.1 ml dimethylsulfoxide was added to the perfusate. Twenty min later ^3H -lysine and ^{14}C -thymidine were added. Liver samples were removed after 15, 30, or 60 min and total cell homogenates or purified nuclear preparations were analyzed for incorporation of the appropriate precursor in DNA, total cell protein, nuclear globulins, acid proteins, histones, and residual proteins. Incorporation of lysine into total serum was linear after a 30 min delay and was not affected by 100 or 500 μg aflatoxin. Lysine incorporation into total liver proteins was inhibited less than 20% by aflatoxin. Incorporation of thymidine into DNA was inhibited 67-75% by 500 μg and 30-60% by 100 μg aflatoxin. Incorporation of lysine into histones and acidic nuclear proteins was depressed to about the same extent as incorporation of thymidine into DNA. Inhibition of lysine incorporation into residual proteins and nuclear globulins was absent or less marked.

4375 BINDING OF CHEMICAL CARCINOGENS TO NUCLEAR PROTEINS OF RAT LIVER. (E.) Jungmann, R. A. (Northwestern U. Med. Sch., Chicago, Ill.) and J. S. Schweppe. *Cancer Res* 32(5):952-959, 1972.

The binding of *N*-hydroxy-*N*-2-fluorenylacetyl- ^{14}C (N-HO-FAA- ^{14}C), *p*-dimethylaminoazobenzene- ^{14}C (DAB- ^{14}C), and 7,12-dimethylbenz(a)anthracene- ^3H (DMBA- ^3H) to histones and acidic proteins of rat liver nuclei was studied. After the injection of the radioactive carcinogens into rats, liver histone fractions F1, F2a1, F2a2, F2b, and F3 were isolated by selective acid extraction. DNA and acidic proteins were extracted with 4 M CsCl at pH 11.6 and 14 and were separated by equilibrium density centrifugation. Histones and acidic proteins were purified by Sephadex chromatography. Maximum levels of bound radioactivity were present in liver histones at 30 to 60 min and in liver nuclear acidic proteins at 60 to 90 min after a single injection of carcinogen. Significant amounts of radioactivity were associated with liver DNA in all experiments. Under the experimental conditions, the hepatocarcinogens N-HO-FAA- ^{14}C and DAB- ^{14}C were bound preferentially to liver histone fractions F2a1 and F2a2, whereas administration of DMBA- ^3H led to the preferential radioactive labeling of the liver histones F1 and F2b. There appeared to be some specificity of carcinogen binding by the nuclear proteins, because pretreatment of rats with nonradioactive carcinogen significantly reduced the extent of labeling after injection of the chemically identical radioactive carcinogen. Pretreatment with nonradioactive carcinogen that was chemically different from the injected radioactive carcinogen did not markedly alter uptake of radioactivity observed without pretreatment.

- 4376 ENHANCEMENT OF URINARY BLADDER TUMORIGENESIS IN HAMSTERS BY COADMINISTRATION OF 2-ACETYLAMINOFLUORENE AND INDOLE. (E.) Oyasu, R. (Northwestern U. Med. Sch., Chicago, Ill.), T. Kitajima, M. L. Hopp and H. Sumie. *Cancer Res* 32(10):2027-2033, 1972.

Hamsters treated with 2-acetylaminofluorene (AAF) were studied to test the effects of dietary indole and excess DL-tryptophan and the initial age of the animals on the development of bladder tumors. Neonatal males and females were given i.p. injections of AAF, 5 mg/100 g body weight, three times weekly until weaning. They were then fed a synthetic diet containing AAF with or without 1.6% indole or 2.0% DL-tryptophan. Enhancement of tumorigenesis in the urinary bladder was evident only when indole was added to the diet containing a low dose of AAF (0.03%). Twenty-four of 27 hamsters fed the combination diet for ten months developed tumors (89%); 20 of them were invasive. On the other hand, 13 of 26 on the diet containing AAF alone developed bladder tumors (50%); eight of them were invasive. The difference in incidence was significant ($p < 0.01$). Development of bladder tumors appeared slightly delayed when older hamsters (initially 4 wk old) were used, but after 11 months all animals developed bladder tumors. As was observed in rats, added indole or tryptophan protected the liver from AAF injury and greatly reduced the development of cholangiocarcinomas.

- 4377 THE CARCINOGENICITY OF INTRAVENOUS NICKEL CARBONYL IN RATS. (E.) Lau, T. J. (U. Connecticut Sch. Med., Farmington), R. L. Hackett and F. W. Sunderman, Jr. *Cancer Res* 32(10):2253-2258, 1972.

The carcinogenicity of i.v. nickel carbonyl, $\text{Ni}(\text{CO})_4$, was tested in Sprague-Dawley rats. In 72 rats (Group A) that survived a single 50% lethal dose injection of $\text{Ni}(\text{CO})_4$ (2.2 mg nickel per 100 g), the incidence of malignant tumors (8.3%) was not significantly greater than the incidence in 47 rats in the control group (4.3%). In 121 rats (Group B) that survived six 5% lethal dose injections of $\text{Ni}(\text{CO})_4$ (0.9 mg nickel per 100 g) at intervals of two or four weeks, the incidence of malignant tumors (15.7%) was significantly greater than in the controls ($p < 0.05$). The 19 malignant tumors in Group B included six undifferentiated sarcomas (lung, pleura, liver, pancreas, uterus, and abdominal wall), three fibrosarcomas (neck, pinna, and orbit), three carcinomas (liver, kidney, and breast), one s.c. hemangioendothelioma, one leukemia, and five lymphomas (lung). This study demonstrates that multiple parenteral injections of $\text{Ni}(\text{CO})_4$ can induce diverse malignant tumors in varied organs and tissues of the rat.

- 4378 THE EFFECT OF VITAMIN A ACID ON GLYCOPROTEIN SYNTHESIS IN SKIN TUMORS (KERATOACANTHOMAS). Levinson, S. S. (Dept. Nutrition Food Sci., Massachusetts Inst. Technol., Cambridge) and G.

Wolf. *Cancer Res* 32(10):2248-2252, 1972.

The metaplasia of rabbit ear skin tumors (keratoacanthomas to mucus-secreting tissue in response to topical application of vitamin A acid [retinoic acid (RA)] was explored biochemically. A 48-hr application of RA stimulated glucosamine- ^{14}C and fucose- ^3H uptake into glycoprotein 5- to 10-fold. The glycoprotein was converted to glycopeptides by proteolytic digestion and was fractionated stepwise on diethylaminoethyl Sephadex A-50. While the uptake of fucose- ^3H was near zero in the 0.2 N fraction from untreated tumors, it was about 1400 dpm/mg (wet weight of tissue) in the equivalent fraction from RA-treated tumors. Glucosamine- ^{14}C uptake into this 0.2 N fraction was stimulated 2- to 3-fold. The effect cannot result from changes in precursor pool size, since other glycopeptide fractions increased only slightly or decreased upon RA treatment. Further purification of the fraction on Sephadex G-75 yielded several glycopeptide components, only one of which showed fucose- ^3H uptake when taken from RA-treated tumors. This component showed a single, symmetrical, ^{14}C , ^3H -labeled peak when rechromatographed on Sephadex G-75 and Sephadex G-50. A time study demonstrated considerable stimulation of isotope uptake into glycoproteins only 4 hr after RA treatment. Radioautography demonstrated that the radioactivity taken up on RA stimulation was in the squamous and connective tissue cells and not in the leukocytes.

- 4379 TOXIC RESPONSE OF RATS TO CYCLAMATES IN CHOW AND SEMISYNTHETIC DIETS. (E.)

Friedman, L. (Bureau Foods, Food Drug Admin., Washington, D.C.), H. L. Richardson, M. E. Richardson, E. J. Lethco, W. C. Wallace and F. M. Sauro. *J Nat Cancer Inst* 49:751-764, 1972.

Cyclamates were fed to rats in two independently conducted studies. In study one, sodium and calcium cyclamate in commercial chow diets were fed, at dietary levels from 0.4-10%, to male and female weanling Osborne-Mendel rats for 101 weeks; in study two, 1 and 2% calcium cyclamate in semisynthetic diets containing 10 and 20% casein were fed to male weanling Holtzman rats for 75 weeks. In both studies, adverse reactions were noted. With the semisynthetic diet, growth rate was depressed, soft stools were produced, and the rate of kidney and urinary bladder lesions was increased. These adverse reactions did not appear to be affected by the protein content of the diet. No observed cytogenetic damage was produced by calcium cyclamate ingestion. With the chow diet, survival decreased and urinary bladder and kidney lesions increased; this increase was much more marked in severity and incidence than that with the semisynthetic diets. The lesions noted with the highest frequency in the kidneys were nephrocalcinosis and calyceal polypoidosis, and in the urinary bladder, epithelial hyperplasia, thickening or edema of the urinary bladder wall, and mucosal papilloma. Transitional cell carcinoma with varying degrees of invasion was detected in the urinary bladders of three of the 23 rats receiving calcium cyclamate in

the chow diets. Two of these carcinomas were in rats fed diets containing only 0.4% of this compound. Bladder calculi were also occasionally present and were in two of the bladders with carcinomas. These lesions were not seen in any rats fed control diets.

4380 INHIBITION OF RAT LIVER RIBONUCLEIC ACID POLYMERASE BY THE CARCINOGEN *N*-HYDROXY-2-FLUORENYLACETAMIDE. (E.) Zieve, F. J. (VA Hosp., Minneapolis, Minn.). *J Biol Chem* 247(18):5987-5995, 1972.

A single i.p. injection of the carcinogenic arylhydroxamic acid *N*-hydroxy-2-fluorenylacetamide given to male rats inhibited the two RNA polymerase activities of isolated liver nuclei by as much as 80%. Low doses of the carcinogen inhibited the Mg^{2+} -dependent polymerase activity preferentially; high doses inhibited the $Mn^{2+} + (NH_4)_2SO_4$ -dependent activity to a greater extent. Inhibition was detectable 15 min after injection of the compound and was maximal in 1 hr. Several related noncarcinogenic compounds and carcinogenic arylhydroxamic acids which were inactive toward the liver completely lacked the inhibitory effect shown by *N*-hydroxy-2-fluorenylacetamide. Female rats, which develop few liver tumors on administration of *N*-hydroxy-2-fluorenylacetamide, were refractory to the inhibition of liver RNA polymerase by this compound. The depression of RNA synthesis by *N*-hydroxy-2-fluorenylacetamide was not due to decreased permeability of the nuclear membrane to substrates, nor to increased hydrolysis of newly synthesized RNA. Similar types of RNA were made in the control and treated rats, and the template capacities of liver chromatin and DNA were not affected by the carcinogen. These data suggest that the inhibition of RNA synthesis by *N*-hydroxy-2-fluorenylacetamide is due to inactivation of the RNA polymerases and not to decreased availability of DNA for transcription.

4381 MUTAGENICITY OF *N*-NITROSOPIPERAZINES FOR *SALMONELLA TYPHIMURIUM* IN THE HOST-MEDIATED ASSAY. (E.) Zeiger, E. (Genetic Toxicol. Branch, Food Drug Admin., Washington, D.C.), M. S. Legator and W. Lijinsky. *Cancer Res* 32:1598-1599, 1972.

Salmonella typhimurium was injected into the peritoneal cavities of mice prior to i.m. inoculation with 1-nitroso-, 1,4-dinitroso-, or 1-nitroso-4-methylpiperazine. These agents were not mutagenic when tested directly against *S. typhimurium* without mediation by a host for the microorganism. In the host-mediated system, however, the three compounds were mutagenic for *S. typhimurium*, as evidenced by increases in his g-46 reversion frequencies in mice given the compounds. The mutagenicity of the nitrosopiperazines in the host-mediated system was apparently a function of the metabolism of nitrosamines.

4382 ROLE OF OVARIAN HORMONES IN MAMMARY TUMORIGENESIS BY A CONTINUOUS ORAL ADMINISTRATION OF *N*-NITROSOBUTYLUREA IN WISTAR/FURTH RATS. (E.) Takizawa, S. (Res. Inst. Nuclear Med. Biol., Hiroshima U., Japan) and T. Yamasaki. *Gann* 62(6):485-493, 1971.

Mammary tumors, mostly adenocarcinoma, were successfully induced in young female rats of Wistar/Furth (W/Fu) strain by a continuous oral administration of *N*-nitrosobutylurea (NBU) in a daily dose of 2.5 or 5 mg per rat, with a relatively short latent period ranging from 6 to 8 months. A larger dose of NBU (10 mg per day) caused marked suppression in body growth, estrous cycle, and the induction rate of mammary tumors. Ovariectomy prior to NBU treatment also abolished the mammary tumorigenic effect of NBU, while orchidectomy was apparently not effective in eliciting mammary tumor in male rats. Restoration of mammary tumor development was attained in castrated rats of both sexes either by supplemental treatment of biweekly injections of 0.4 mg of progesterone and 0.01 mg of estradiol benzoate combined, or by ovarian isograft implanted under the kidney capsule. There was a slowdown in the restoration of mammary tumor development in the ovariectomized and hormone-treated rats as compared to the male counterparts. Nevertheless, shortly after the cessation of hormone treatment in the 7th month after the beginning of NBU treatment, there occurred a rapid increase in induction rate of mammary tumors in the ovariectomized and hormone-treated rats. The castrated male rats were found to be a useful tool for testing the mammary tumorigenicity of unknown agents, if conditioned adequately with ovarian hormones, by their excellent productivity of mammary tumors in terms of incidence, multiplicity, and growth rate of the tumor.

4383 EXPERIMENTAL INDUCTION OF EPIDERMOID CARCINOMA IN THE LUNGS OF RATS BY CIGARETTE SMOKE CONDENSATE. (E.) Stanton, M. F. (Nat'l. Cancer Inst., Bethesda, Md.), E. Miller, C. Wrench and R. Blackwell. *J Nat Cancer Inst* 49(3):867-877, 1972.

Epidermoid carcinomas and preneoplastic lesions characterized by keratinizing squamous metaplasia were induced in the lungs of female, Osborne-Mendel rats by direct injection into the lung of 0.05-0.10 ml warm, liquefied beeswax containing either crude cigarette smoke condensate (CSC) or heptane soluble fraction (HSF) of this condensate. Control pellets containing beeswax and tricaprillin or beeswax and either anthracene, unburned cigarette tobacco, or cigarette ash were enveloped by non-reactive epithelial tissue in a mild granulation tissue stroma. Beeswax pellets containing either CSC or HSF were enveloped by metaplastic epithelium in 45 of 55 rats dying the 1st year after implantation. During the 2d year, 106 of the 303 remaining rats died. Of these, 44 had metaplastic lesions and 31 had epidermoid carcinomas at the pellet site. No dose-response relationship was noted over the relatively narrow range of 12-72

mg HFE used. The consistently high incidence of neoplasms induced by the condensate of < 5 cigarettes indicates a highly sensitive system for study of the carcinogenicity of various CSC fractions. The metaplastic response, which develops within four weeks at the pellet site, may be of further value in the rapid assessment of tobacco products and other materials potentially carcinogenic for the lung.

- 4384 AUTORADIOGRAPHIC STUDY ON LOCALIZATION OF FIBRINOGEN IN RABBIT LUNG CANCER. (E.) Ogura, T. (Osaka U. Med. Sch., Japan), F. Hirao, E. Tsubura and Y. Yamamura. *Gann* 62(5):367-372, 1971.

The distribution of ^{131}I -labeled fibrinogen was studied by macro- and micro-autoradiography in ten rabbits bearing lung cancer induced by intra-bronchial infusion of 3-methylcholanthrene and 4-nitroquinoline 1-oxide or 3-methylcholanthrene alone. The localization of fibrinogen was invariably observed in the non-cancerous pulmonary tissues around and adjacent to the induced cancer tissues, irrespective of histological type of cancer tissues. However, the localization of fibrinogen in cancer tissue itself was observed in a few rabbits and it was observed limitedly in the interstitial spaces and desquamated cells. The extrapulmonary tumors by the transpleural invasion of the induced cancer showed the most preferential localization of fibrinogen. It is concluded that fibrinogen localization in and around the cancer tissue of rabbits resulted from deposition in cancer tissue itself and an interaction of tumor tissues with the host. It is postulated that similar events would occur in human patients with lung cancer because no distinct difference lies in macro- and microscopic findings of lung cancer between humans and rabbits.

- 4385 HISTOPATHOLOGICAL AND ULTRASTRUCTURAL STUDIES ON ESOPHAGEAL TUMORS IN RATS TREATED WITH N-NITROSOPIPERIDINE. (E.) Ito, N. (Nara Med. U., Japan), Y. Kamamoto, Y. Hiasa, S. Makiura, M. Marugami, Y. Yokota, S. Sugihara and K. Hirao. *Gann* 62(6):445-451, 1971.

The histogenesis of esophageal tumors in male Wistar strain rats on oral administration of 0.03% N-nitrosopiperidine was studied by light and electron microscopy. Hyperplasia of the esophageal epithelium was seen within 4 wk and papilloma within 8 wk. Cancer developed after 12 wk administration of N-nitrosopiperidine. After administration of N-nitrosopiperidine for 20 wk, 9 of 11 rats (81.8%) had developed esophageal cancer. Histologically, the esophageal cancer in rats induced by N-nitrosopiperidine was a squamous cell carcinoma, which was rich in cornification and closely resembled those produced in the esophagus on administration of other chemical carcinogens. No adenocarcinoma or benign neoplasia of the esophagus was observed. Histological changes in the esophageal epithelium

increased in frequency and extent with the period of administration of N-nitrosopiperidine. The present investigation suggests that hyperplasia is a precursor of esophageal carcinoma in rats administered with N-nitrosopiperidine but that cornification and hyperkeratosis of the esophageal epithelium were not significantly preneoplastic changes.

- 4386 LIVER MICROSOMAL METABOLISM OF AFLATOXIN B_1 TO A REACTIVE DERIVATIVE TOXIC TO *SALMONELLA TYPHIMURIUM* TA 1530. (E.) Garner, R. C. (U. Wisconsin Med. Ctr., Madison), E. C. Miller and J. A. Miller. *Cancer Res* 32:2058-2066, 1972.

A reduction in the survival of *Salmonella typhimurium* TA 1530 was observed when the bacteria were incubated with aflatoxin B_1 , rat liver microsomes, and a reduced nicotinamide adenine dinucleotide phosphate-generating system. The lethality appeared to depend on the formation of a metabolite of aflatoxin B_1 by a mixed-function oxygenase system. The killing was very rapid; only 1% of the bacteria were able to form colonies after 2 min of incubation with large amounts of microsomes and aflatoxin B_1 . Attempts to separate the toxic metabolite from the microsomal system were not successful. Toxic metabolites for *S. typhimurium* TA 1530 were also formed if aflatoxin B_1 was replaced by either aflatoxin G_1 or sterigmatocystin in the microsome-mediated toxicity assay. Except for aflatoxin G_1 , the derivatives that were tested either had much less activity or were inactive. The livers from a number of other species of rodents and a single autopsy sample of human liver also were active in the microsome-mediated aflatoxin B_1 toxicity assay. The addition of RNA or DNA to the incubation mixture inhibited the killing of the bacteria. The RNA (which was reisolated after its incubation with aflatoxin B_1), liver microsomes, and a reduced nicotinamide adenine dinucleotide phosphate-generating system showed a low, broad absorption, with a maximum at 366 to 370 nm. This high wavelength absorption was not removed by Sephadex G-10 chromatography of the RNA or by extraction procedures and appeared to be attributable to covalently bound aflatoxin B_1 derivative(s). The formation of the conjugated RNA was dependent on reduced nicotinamide adenine dinucleotide phosphate and was inhibited by the addition of aniline; the amount formed was a function of the activity of the mixed-function oxygenases in the incubation mixture. It is tentatively suggested that the derivative that is toxic to *S. typhimurium* TA 1530 and the one that reacts with nucleic acids are identical. The possible relationship of this derivative to the hepatocarcinogenicity of aflatoxin B_1 is discussed.

- 4387 LYMPHATIC LEUKEMIA AND PULMONARY TUMORS IN FEMALE SWISS MICE FED BRACKEN FERN (*PTERIS AQUILINA*). (E.) Pamukcu, A. M. (Coll. Vet. Med., U. Ankara, Turkey), E. Ertük, J. M. Price and G. T.

Bryan. *Cancer Res* 32:1442-1445, 1972.

Forty Swiss mice were fed a mixture of grain diet and bracken fern (two parts grain to one part bracken) on alternate weeks for 60 weeks, for a total mean maximum dose of 315 g bracken/mouse. All of the 33 mice surviving more than 30 weeks developed lymphatic leukemia involving lymph nodes, kidney, liver and lungs. No mice given grain diet alone without bracken fern developed leukemia. In addition, five of the surviving experimental mice developed multiple primary lung tumors. Though bracken fern has been associated with urinary bladder and intestinal tumorigenesis, neither bladder nor intestinal tumors were seen in bracken-fed mice in these experiments.

4388 URINARY EXCRETION OF FREE AND CONJUGATED FORMS OF 3-HYDROXYANTHRANILIC ACID.

(E.) Watanabe, M. (Natl. Inst. Hyg. Sci., Tokyo, Japan), K. Minegishi and Y. Tsutsui. *Cancer Res* 32(10):2049-2053, 1972.

Urinary excretion of free and conjugated forms (glucuronide and sulfuric ester) of 3-hydroxyanthranilic acid, a metabolite of tryptophan which is suspected to have carcinogenic action, was studied. The patterns of excretion of these three substances in the urine of humans, rats, and guinea pigs were determined by fluorometry. The conjugated forms were estimated after separation by stepwise elution from diethylaminoethyl Sephadex column chromatography and thin-layer chromatography. Hydrolysis of these conjugated forms added to the urine was also studied. The patterns of urinary excretion of these compounds change markedly in different animal species. The compounds excreted were mainly a nonconjugated form in humans, the sulfuric ester in rats, and the glucuronide in guinea pigs. When tryptophan was administered, the nonconjugated form increased mainly in humans while the sulfuric ester increased mainly in rats. No marked increase of the metabolites was found in guinea pigs. On the other hand, there was no significant decrease in the conjugated forms that were added to the urines, except in the case of the glucuronide in rat urine.

4389 ABSENCE OF STAINABLE IRON FROM PRENEOPLASTIC AND NEOPLASTIC LESIONS IN RAT LIVER WITH 8-HYDROXYQUINOLINE-INDUCED SIDEROSIS. (E.)

Williams, G. M. (Natl. Cancer Inst., Bethesda, Md) and R. S. Yamamoto. *J Nat Cancer Inst* 49(3):685-692, 1972.

Detailed comparative studies were conducted on the progressive increase in stainable iron deposition in normal, preneoplastic, and neoplastic tissues of rats fed diets containing 8-hydroxyquinoline (HQ), with or without further supplements of iron as ferrous gluconate (FG). HQ induced hepatic iron deposition and this was enhanced by FG at all time points. However, even very minimal liver lesions induced by the hepatocarcinogens diethylnitrosamine or N-2-

fluorenylacetamide, barely recognizable by standard hematoxylin and eosin staining techniques, stood out clearly because they did not accumulate stainable iron like the adjoining hepatocytes. Hepatic hyperplastic and neoplastic lesions of increasing severity seen during continuing carcinogen treatment characteristically did not exhibit siderosis. Thus iron stains in the livers of rats fed HQ and FG permit the sensitive and reliable detection of early hyperplastic or neoplastic lesions. Rats ingesting HQ in addition to the carcinogens had a lower incidence of hepatic malignancy.

4390 MAMMARY CARCINOGENESIS IN FEMALE AND MALE MICE RECEIVING CONTRACEPTIVES OR GESTAGENS.

(E.) Rudali, G. (Curie Fdn., Inst. Radium, Paris, France), E. Coezy and R. Chemama. *J Nat Cancer Inst* 49(3):813-819, 1972.

Three widely used estrogen-progestin mixtures (Enovid, Ovulen, and Lutestral) and their gestagens were investigated as potential carcinogens in the mammary gland of C3H, RIII, and (C3H X RIII)_{F1} intact female mice. The various contraceptives, despite their estrogen content, did not accelerate or raise the frequency of mammary carcinogenesis in these animals. Norethynodrel and chlormadinone acetate significantly delayed the appearance of the tumors. All three contraceptives produced, with a high rate and after short latencies, mammary cancers in castrated (C3H X RIII)_{F1} males. Norethynodrel was as potent as mestranol. Chlormadinone acetate did not produce mammary cancers in these males. Some castrated control males developed spontaneous mammary carcinomas late in life, probably induced by adrenal secretions. The castrated male mouse of susceptible strains seems promising material for the establishment of a potential carcinogenic risk for the mammary gland.

4391 RETICULOSES AND EPIDERMAL TUMORS IN HAIRLESS MICE AFTER TOPICAL SKIN APPLICATIONS OF CANTHARIDIN AND ASIATICOSIDE. (E.)

Laerum, O. D. (Inst. Gen. Exp. Path., U. Oslo, Norway) and O. H. Iversen. *Cancer Res* 32:1463-1469, 1972.

Hr/hr hairless mice were given 3-methylcholanthrene (MCA) by topical painting 14 days before the start of a lifelong course of painting with 0.016% cantharidin dissolved in benzene. Other mice were painted with cantharidin alone, MCA and lifelong 0.1% asiaticoside, asiaticoside alone, or MCA and benzene. Cantharidin in benzene was a weak but complete carcinogen; mice given cantharidin and MCA developed squamous carcinomas in 7.1% of cases and mice given cantharidin alone developed carcinomas in 6.3% of cases. Benzene after MCA gave a 2.9% carcinoma incidence. Asiaticoside after MCA produced sarcomas of the dermis in 3.4% of mice; asiaticoside alone produced a 2.5% sarcoma incidence. In mice given cantharidin and MCA, carcinomas developed after 16 months of observation. Prior to carcinoma appearance, mice given cantharidin and MCA had a

lower incidence of skin papillomas than mice given MCA and benzene. This suggested that in the early stages of painting, cantharidin inhibited tumor growth. On autopsy, it was found that mice given cantharidin and MCA had developed reticuloses and malignant lymphomas in 56% of cases, while the incidence of these tumors in mice given MCA and benzene was 25%. Cantharidin alone, and MCA and asiaticoside, produced reticuloses and lymphomas in 28% of cases. Cantharidin apparently penetrated the skin to cause reticuloendothelial system tumors in treated mice.

- 4392 SYSTEMIC PROMOTING ACTION OF PHORBOL IN LIVER AND LUNG CARCINOGENESIS IN AKR MICE. (E.) Armuth, V. (Weizmann Inst. Sci., Rehovot, Israel) and I. Berenblum. *Cancer Res* 32(10):2259-2262, 1972.

Newborn male and female AKR mice receiving a single s.c. injection of dimethylnitrosamine (DMN) and, after a 2-wk interval, repeated i.p. injections of phorbol, developed lung adenomas and hepatomas in a high percentage of survivors. When a higher dose of DMN was injected into 10-day-old AKR mice with subsequent phorbol treatment, the incidence of lung adenomas and hepatomas was low; while no such tumors appeared in the untreated mice or in those receiving phorbol alone, and very few tumors appeared in the DMN control mice. The results thus demonstrate a pronounced promoting action by phorbol on lung and liver carcinogenesis provided that the initiating stimulus (by DMN) was given soon after birth. Phorbol, whether administered alone or after initial treatment with DMN, failed to increase the spontaneous incidence of thymic leukemia.

- 4393 RIBOSOME MONOMERS IN RAT LIVER FOLLOWING ADMINISTRATION OF DIMETHYLNITROSAMINE. (E.) Vernie, L. N. (Netherlands Cancer Inst., Amsterdam), W. S. Bont and P. Emmelot. *Cancer Res* 31:2189-2195, 1971.

Adult rats were injected i.v. with 50 mg/kg of dimethylnitrosamine (DMNA). Five hr later, the rats were killed, their livers were removed, and free and membrane-bound liver polyribosomes were isolated. Polyribosome preparations were subjected to sucrose gradient centrifugation. DMNA administration led to a marked increase in the 77S ribosomes present in free and membrane-bound polyribosome preparations. The 77S particles were not labeled by radioactive amino acid *in vivo*, and their presence in the membrane-bound polyribosomes appeared to be mainly artifactual. When 77S particle-containing polyribosome fractions were applied to Sephadex G-25 and eluted with buffer containing 0.5 mM Mg^{++} , most sedimenting material appeared as 59S particles. In this, the 77S ribosomes resembled "runoff" ribosomes, i.e., ribosomes released from normal polyribosomes *in vitro* under conditions of amino acid incorporation at $(Mg^{++}) < 7mM$. The inhibition of amino acid incorporation in polyribosomal preparations

from DMNA-treated liver was a function of the amount of 77S ribosomes in these preparations. It was concluded that DMNA causes accumulation of runoff type ribosome monomers in the liver at the expense of polyribosomes which otherwise function normally in amino acid incorporation.

- 4394 COORDINATED BIOCHEMICAL AND MORPHOLOGIC EXAMINATION OF HAMSTER TRACHEAL EPITHELIUM. (E.) Kaufman, D. G. (Natl. Cancer Inst., Bethesda, Md.), M. S. Baker, C. C. Harris, J. M. Smith, H. Boren, M. B. Sporn and U. Saffiotti. *Nat Cancer Inst* 49(3):783-792, 1972.

A respiratory epithelium of the hamster was examined by autoradiographic and biochemical techniques. Normal morphology was preserved in tracheas maintained *in vitro* for up to 3 hr. Biochemical analyses could be performed on epithelial cells obtained from the tracheal segments. Maintenance of isolated tracheal segments *in vitro* permitted far greater incorporation of radioactively labeled precursors as compared to administration *in vivo*. 3H -5-uridine was incorporated into high molecular weight RNA *in vitro* and "maturation" of ribosomal RNA species occurred *in vitro*. Biochemical events were correlated with cell type by concurrent quantitative autoradiography. Basal cells incorporated less 3H -5-uridine than mucous or ciliated cells. Correlated biochemical and morphologic study may be a means of evaluating biochemical changes in the presence of altered cell populations after carcinogen administration.

- 4395 REPAIR MECHANISM IN SENDAI VIRUS CARRYING HeLa CELLS AFTER DAMAGE BY 4-HYDROXYAMINO-QUINOLINE 1-OXIDE. (E.) Satoh, T. (Temple U. Sch. Med., Philadelphia, Pa.) and N. Yamamoto. *Cancer Res* 32(2):440-443, 1972.

HeLa cells infected with Sendai virus (HJV) and established as a carrier culture (HeLa HJV) were treated with 4-nitroquinoline 1-oxide (4NQO) or its metabolite, 4-hydroxyaminoquinoline 1-oxide (4HAQO). Cellular "inactivation" (measured by colony-forming ability seven days after treatment) and diaphorase activity (assayed spectrophotometrically) were determined. Both HeLa and HeLa (HJV) cells demonstrated similar diaphorase activity, indicating that both types were capable of producing the same amounts of 4HAQO from 4NQO. Incubation in 4HAQO (10 μM) for periods required for 10- to 100-fold inactivation of HeLa cells caused only 30-60% inactivation of HeLa (HJV) cells. This result was similar to the previously reported UV- and 4NQO-sensitivities of these cells and indicated that HeLa (HJV) cells have a greater capacity to repair damaged genomes than HeLa cells. When HeLa and HeLa (HJV) cells were incubated one hr at 37 C with 4HAQO (10^{-5} to 10^{-6} M), colony-forming ability decreased as 4HAQO concentration increased. HeLa (HJV) cells were again more resistant to 4HAQO than HeLa cells. The reparability of 4HAQO-damaged (1.0 μM) herpes simplex virus (HSV) was determined by plaque assay in HeLa and HeLa (HJV) cells. Incubation periods required for 10- to 100-fold inactivation of HSV

assayed on HeLa cells produced 3- to 10-fold inactivation on HeLa (HJV) cells, indicating that HeLa (HJV) cells are also more effective than HeLa cells in repairing foreign genomes.

- 4396 TRANSFORMATION OF HUMAN EMBRYO LUNG CELLS BY THE ACTION OF URETHANE AND INFLUENZA VIRUS. (E.) Frolov, A. F. (Res. Inst. Epidemiol. Microbiol. Parasitol., Kiev, USSR), A. M. Shcherbinskaya and N. E. Botsman. *Folia Biol* 17(6):421-423, 1971. 421-423, 1971.

Organ cultures of human embryonic lung were exposed to 2.0% urethane ethyl carbamate No. 13978 (24 hr) or infected with influenza virus type A2, strain 2260 (two hr) or were exposed to urethane followed by virus infection. Explants were stained and examined for morphological transformation 6, 12 and 15 days after the beginning of the experiment. Thirteen of 20 untreated explants became necrotic after one wk of cultivation and by 15 days signs of necrosis were evident throughout the whole explant. Diffuse cellular proliferation occurred primarily around the margins of the explants during the first days. Necrosis of explants treated with urethane was accelerated compared with controls but the patterns were essentially identical. Urethane not only induced diffuse proliferative changes like those seen in controls, but also caused formation of separate foci of hyperplastic tissue consisting of cells with oval or ring-shaped and, in some cases, hyperchromic nuclei. Virus infection induced proliferative changes which were evident after the 15th day. Foci of small polymorphic cells with hyperchromic nuclei were observed. Alveolar and bronchial lumens became filled with proliferating cells and eosinophilic masses. Mitotic anomalies were observed which, together with the changes in cell morphology, were interpreted as anaplasia. Combined treatment with urethane and influenza virus produced an accentuated hyperplastic response. Inter-alveolar partitions became thickened, proliferating alveolar cells filled bronchial and alveolar lumens, and normal pulmonary morphology was destroyed. Papillomatous structures consisting of large polymorphic cells were seen up to the 20th day. Cell "anaplasia" was common.

- 4397 ESTIMATION OF INTERSTRAND DNA CROSS-LINKING RESULTING FROM MUSTARD GAS ALKYLATION OF HeLa CELLS. (E.) Ball, C. R. (Sch. Med., Leeds, England) and J. J. Roberts. *Chem Biol Interact* 4(4):297-303, 1972.

An isopycnic gradient technique was used to quantitatively estimate the degree of intrastrand cross-linking of DNA in cultured HeLa cells resulting from treatment with the difunctional alkylating agent mustard gas. HeLa cells were grown in medium containing a density label (BUdR, 5 µg/ml, 20 hr) or in medium containing BUdR (three hr) followed by medium containing ³H-thymidine (³HTdR) and fresh BUdR (three hr), followed by incubation in medium containing fresh BUdR (one hr). The cells were then treated with mustard gas (0.1%, v/v) in methanol

or methanol only (control) for 30 min. Finally, DNA was isolated and analyzed by alkaline CsCl equilibrium density gradient centrifugation. DNA from 20 hr BUdR-labeled cells showed two peaks on CsCl gradients, one corresponding to the "light" template strand and one to the "heavy" newly synthesized strand. Treatment of these cells with mustard gas produced a third peak of intermediate density, which resulted from formation of covalent bonds between the "light" and "heavy" strands. A quantitative estimation of the degree of mustard gas-induced cross-linking was achieved by labeling the "heavy" newly synthesized DNA with a pulse of ³H-TdR. Under these conditions only cross-linked DNA strands and nonlinked "heavy" strands were radioactive. The relationship between mustard gas concentration and the extent of DNA cross-linking was investigated. The degree of cross-linking was calculated from the difference in areas under the plotted radioactivity curves between controls and mustard gas-treated cells. The amount of DNA cross-linking was linear for mustard gas concentrations between 0.5 µg/ml (9% cross-linking) and 2.0 µg/ml (35% cross-linking). This method was relatively insensitive for mustard gas concentrations less than 0.05 µg/ml due to shearing of DNA molecules during the phenol extraction.

- 4398 ALTERED MORPHOLOGY AND BEHAVIOUR OF KIDNEY FIBROBLASTS *IN VITRO*, FOLLOWING *IN VIVO* TREATMENT OF RATS WITH A CARCINOGENIC DOSE OF DIMETHYLNITROSAMINE. (E.) Hard, G. C. (Toxicol. Unit., Med. Res. Council Labs, Carshalton, England), R. Borland and W. H. Butler. *Experientia* 27:1208-1209, 1971.

Increase in cell size, nuclear size and number, abnormalities of mitochondria and nucleoli, and abnormal cells with cytoplasm filled with randomly arrayed microfilaments are characteristics of transformed fibroblast-like cells which initiate mesenchymal tumors and which may be found in persisting inflammatory lesions *in vivo* as early as 3 wk following dimethylnitrosamine (DMN) treatment of rats. To determine if similar changes occur *in vitro*, male Wistar rats fed sucrose and water for three days were injected i.p. with 60 mg/kg DMN. Renal cortical tissue was removed and cultured after seven days, and the cytological characteristics were compared with those of renal cortical cells cultured from normal controls. Fourteen days after initiation, control cultures consisted mainly of groups of epithelial cells surrounded by fibroblastic cells, while cultures from DMN-treated rats showed clusters of piled-up fibroblastic cells growing in disarray. Cells and their nuclei displayed considerable pleomorphism and nucleoli were enlarged. Some cells were multinucleate and abnormal mitoses were seen. Cells with retracted cytoplasm appeared to be detaching from cytoplasm of larger, multinucleated cells within the clusters. Electron microscopic observations confirmed the morphological alterations seen under light microscope. In addition, nucleolar fragmentation and cytoplasm filled with sheets of microfilaments were observed. These observa-

tions suggest that the cytological characteristics of cultured renal tissue from DMN-treated rats could be due to unimpeded *in vitro* development of cells transformed *in vivo*.

- 4399 TUMOUR FORMATION IN MICE BY URETHANE ADMINISTERED WITH RELATED CARBAMATES. (E.) Pound, A. W. (Dept. Path., U. Queensland, Brisbane, Australia). *Brit J Cancer* 26(3):216-225, 1972.

A tumor initiating dose of ethyl carbamate was administered to mice by s.c. injection together with a dose of one of the homologous esters or an ethyl N-alkyl derivative. The homologues used were the methyl, *n*-propyl and *n*-butyl esters, and the derivatives were the N-methyl, N-ethyl and N-*n*-propyl ethyl esters. The mice were then given promoting treatment with croton oil for 28 weeks. Neither the homologous esters nor the N-substituted derivatives of ethyl carbamate had any influence on the yield of tumors in the skin, lung, or liver. However, increasing the dose of ethyl carbamate increased the yields of tumors.

- 4400 DNA BINDING AND INHIBITION OF DNA SYNTHESIS AFTER 7,12-DIMETHYLBENZ(a)ANTHRACENE ADMINISTERED DURING THE EARLY PREREPLICATIVE PHASE IN REGENERATING RAT LIVER. (E.) Marquardt, H. (Sloan-Kettering Inst. Cancer Res., New York, N. Y.), F. S. Philips and A. Bendich. *Cancer Res* 32:1810-1813, 1972.

7,12-Dimethylbenz(a)anthracene (DMBA), given i.v. 24 hr after partial hepatectomy when DNA replication is maximal, binds tightly to DNA, inhibits its synthesis, and induces neoplastic changes in regenerating rat liver. DMBA injected i.v. 5 hr after partial hepatectomy (*i.e.*, during the early prereplicative phase) inhibits DNA synthesis for at least 48 hr. The amount of tritiated DMBA bound to DNA by 11 hr equals the maximum amount found in intact rat liver; however, from 11 to 24 hr the amount bound to DNA increases 2- to 3-fold (in untreated regenerating rat liver, DNA synthesis begins 16 hr after partial hepatectomy). In the small intestine, in which DNA synthesis is continuous and relatively constant in rate, the amount of DMBA bound to DNA is maximal by 11 hr. The amount of DNA-bound benz(a)anthracene given i.v. 5 hr after partial hepatectomy decreases from 11 to 24 hr. Binding of DMBA in regenerating rat liver persists for at least four weeks; in small intestine the amount of DNA-bound carcinogen decreases at a rate suggesting loss by cell renewal. It appears that, on entry into the replicative phase, DNA becomes more susceptible to binding and the bound carcinogen persists in surviving cells.

- 4401 ANTIGENIC DIVERSITY OF TUMORS CHEMICALLY INDUCED WITHIN THE PROGENY OF A SINGLE CELL. (E.) Basombrio, M. A. (Inst. Cancer Res., Philadelphia, Pa.) and R. T. Prehn. *Int J Cancer* 10:1-8, 1972.

BALB/c 3T3 mouse cells were cloned and cells from

different clonal sublines were placed in diffusion chambers with 3-methylcholanthrene (MCA) and implanted into abdomens of thymectomized, X-irradiated BALB/cCR mice. Of 47 mice given diffusion chambers containing MCA-transformed clonal cells, 23 developed tumors. The antigenic characters of these tumors were determined by immunizing mice with cells of different tumors and challenging recipients with tumor cells. Results showed that tumors induced by the various transformed cloned cells had different antigenic determinants, even though all tumors had been derived from the same cell. It was concluded that the antigenic diversity of chemically induced tumors could not be explained solely on the basis of cloning pre-existing variants.

- 4402 PLASMA PROTEIN SYNTHESIS BY N-2-FLUORENYLACETAMIDE-INDUCED PRIMARY HEPATOCELLULAR CARCINOMAS AND HEPATIC NODULES. (E.) Becker, F. F. (New York U. Sch. Med., N.Y.), K. M. Klein and R. Asofsky. *Cancer Res* 32(5):914-920, 1972.

Hepatic nodules and hepatocellular carcinomas were induced in rat livers by the ingestion of N-2-fluorenylacetamide. The ability of these tissues to synthesize normal plasma proteins was examined *in vitro* by immunoelectrophoresis radioautography. Two patterns of protein synthesis were detected when these tissues were compared with that of normal livers. The first, suppression of protein production, was seen mainly in nodules examined soon after the cessation of carcinogen ingestion. The second, acceleration of production, was seen in nodules examined later in their history and in most hepatocellular carcinomas. The pattern of protein synthesis often varied from one nodule to another within a single liver. In addition, the type of alteration in production of one protein within a single nodule was often independent of that which affected others. These findings suggested that the alterations in protein synthesis were specific for selective effects of the carcinogen and that they were related to events in carcinogenic evolution.

- 4403 THE EFFECT OF BENZPYRENE, PHENOBARBITAL, AND CARBON TETRACHLORIDE ON SUBCELLULAR METAL DISTRIBUTION AND MICROSOMAL ENZYME ACTIVITY. (E.) Moffitt, A. E., Jr. (United States Pub. Hlth. Serv., Cincinnati, O.), J. R. Dixon, F. C. Phipps and H. E. Stokinger. *Cancer Res* 32:1148-1153, 1972.

Male rats were given a single 8 mg dose of benzo(a)-pyrene (BP) intratracheally; other rats were given 75 mg/kg/day phenobarbital for three days, and a third group was given carbon tetrachloride p.o. in single doses of 0.25, 0.50 or 1.00 mg/kg. Rats were killed 24, 72 or 240 hr after treatment and lungs and liver were removed. Subcellular fractions of lungs and livers were prepared by differential centrifugation and metal concentrations in subcellular organ fractions were determined by atomic absorption spectrophotometry. The BP dose caused a fourfold increase in lung microsomal copper at 72 hr

as compared to untreated controls. BP also produced a sixfold increase in lung BP hydroxylase at 72 hr; this suggested that the increase in lung microsomal copper may have been associated with an increase in microsomal enzyme activity. BP also caused a fourfold increase in lung microsomal manganese, a 40% depression in nuclear manganese, a decrease in lung nuclear, mitochondrial and microsomal nickel, and a decrease in chromium in these lung fractions. Phenobarbital increased liver microsomal copper, manganese and zinc. However, carbon tetrachloride reduced liver microsomal copper, manganese and zinc, as well as liver aniline hydroxylase activity.

- 4404 RAPID DEVELOPMENT OF BRONCHIOLO-ALVEOLAR SQUAMOUS CELL TUMORS IN RATS AFTER INTRA-TRACHEAL INJECTION OF 3-METHYLCHOLANTHRENE. (E.) Schreiber, H. (Biol. Div., Oak Ridge Natl. Lab., Tenn.), P. Nettesheim and D. H. Martin. *J Nat Cancer Inst* 49(2):541-554, 1972.

Specific-pathogen-free inbred male Fischer 344 rats received intratracheal injections totaling 25 mg (5 mg per wk) or 10 mg (single injection) of 3-methylcholanthrene. Multiple, small tumor nodules developed in the lungs two wk following injection of the last 5 mg of the 25 mg dose or five wk after injection of the 10 mg dose. The tumors, which were identified histologically as bronchiolo-alveolar squamous cell carcinomas, spread rapidly into the lung parenchyma and occupied most of the lung area by 8 wk after injection of the last 5 mg of the 25 mg dose. Although the tumors were highly proliferative, they initially appeared histologically benign and were not readily transplanted by s.c. or i.m. transfer into adult and newborn isogenic hosts. However, two lung tumors transplanted five wk and one transplanted 13 wk after the last dose of the 25 mg series began to grow progressively five to eight months after transplantation. Serial passages of these tumors were successful.

- 4405 SKIN CARCINOGENESIS TESTS OF HYDROGENATED DERIVATIVES OF ANTHANTHRENE AND OTHER POLYNUCLEAR HYDROCARBONS. (E.) Lijinsky, W. (Eppley Inst. Cancer Res., Omaha, Neb.) and H. Garcia. *Z Krebsforsch* 77(3):226-230, 1972.

Five polynuclear hydrocarbons were tested for carcinogenicity by topical application to the skin of random bred Swiss female mice twice weekly for 50 to 72 weeks. Anthanthrene, 4,5-dihydroanthanthrene and 1,2,3,7,8,9-hexahydroanthanthrene were noncarcinogenic. 5,6-dihydro-7,12-dimethylbenz(a)anthracene and 6,7,8,9,10,12b-hexahydro-3-methylcholanthrene produced squamous cell papillomas and carcinomas of the skin in 50% and 67% of the animals, resp. Mean latent periods were 43 and 50 days, resp. These results support earlier findings that, given a polynuclear hydrocarbon molecule possessing some minimal chemical reactivity, the main criterion of carcinogenic activity is the size and shape of the molecule.

- 4406 ESTRADIOL RECEPTORS IN MOUSE MAMMARY TUMORS: ABSENCE OF THE TRANSFER OF BOUND ESTRADIOL FROM THE CYTOPLASM TO THE NUCLEUS. (E.) Shyamala, G. (Dept. Zool., U. California, Berkeley). *Biochem Biophys Res Commun* 46(4):1623-1630, 1972.

Spontaneous estradiol-independent mammary tumors were taken from GRS/A mice, incubated with 6-7-³H-estradiol-17 β (³H-E₂), homogenized, and tested by sucrose density centrifugation for cytoplasmic and nuclear binding of estradiol in tumor cells. Two discrete estradiol binding components were seen on sucrose density gradients; one had a sedimentation coefficient of 4-5S, the other of 8S. Total binding capacity for the 8S estradiol receptor was 0.02 pmoles/100 μ g DNA. Treatment of the tumor cytoplasm with proteolytic enzymes abolished ³H-E₂ binding, suggesting that the binding component was a protein. In these and other respects, the binding characteristics of the 8S component were similar to those of the 8S estradiol receptor complex of the uterus. Tumor cells, however, showed no significant intranuclear binding of ³H-E₂.

- 4407 A CORRELATIVE HISTOCYTOLOGICAL STUDY OF CARCINOMA AND EPITHELIAL ATYPIA OF THE PALATE AMONG INDIAN REVERSE SMOKERS. (E.) Mehta, F. S. (Tata Inst. Fund. Res., Bombay, India), B. E. Sahiar, D. K. Daftary, P. C. Gupta and J. J. Pundborg. *Brit J Cancer* 26(3):230-233, 1972.

A correlative histocytological study was made of six patients with palatal carcinomata and 342 patients with palatal lesions (primarily leukoplakias) associated with reverse smoking from the Srikakulam district of Andhra Pradesh. Among six histologically diagnosed carcinomata only two showed cytological findings typical of carcinoma. Of the 46 atypias diagnosed histologically among the other palatal lesions, only six (13%) were diagnosed cytologically. Findings show that cytological examination of precancerous and cancerous lesions located on the hard palate, which is a highly keratinized area of the oral cavity, may not be reliable enough for revealing premalignant or malignant changes.

- 4408 CARCINOGENESIS ASSAY OF SUBFRACTIONS OF CIGARETTE SMOKE CONDENSATE PREPARED BY SOLVENT-SOLVENT SEPARATION OF THE NEUTRAL FRACTION. (E.) Bock, F. G. (Roswell Park Mem. Inst., Buffalo, N.Y.), A. P. Swain and R. L. Stedman. *J Nat Cancer Inst* 49(2):477-483, 1972.

Carcinogenesis assay was conducted on subfractions of the neutral fraction (NF) of cigarette smoke condensate, subfractions that were prepared by solvent partition. Of the two major subfractions, the "methanolinsoluble" neutrals (MIN) were much more active than the "methanolinsoluble" neutrals (MSN). Distribution of MSN between nitromethane and carbon disulfide yielded two active fractions. Poor dose-response effects suggested that extraneous materials may reduce the activity of MSN. Analysis of the

recovery of MSN is difficult, but apparently there were significant losses during separation. On counter-current distribution (CCD), MIN yielded three active and two inactive subfractions. Recovery of the activity of MIN in the subfractions was excellent in comparison with an earlier separation with silicic acid chromatography. Recoveries might be improved if CCD is applied to the NF before the more rigorous chromatographic separations.

- 4409 EXPRESSION OF BENZ(a)ANTHRACENE-INDUCIBLE ARYL HYDROCARBON HYDROXYLASE ACTIVITY IN MOUSE-HAMSTER AND MOUSE-HUMAN SOMATIC-CELL HYBRIDS. (E.) Benedict, W. F. (Natl. Inst. Child Hlth. Human Devel., Bethesda, Md.), B. Paul and D. N. Nebert. *Biochem Biophys Res Commun* 48(2):293-298, 1972.

Somatic cell hybrids were formed by fusion of 3T3 mouse cells and human D98 cells or BHK hamster cells. Aryl hydrocarbon hydroxylase (AHH) could be induced by benz(a)anthracene (BA) in 3T3 cells, but there was no AHH induction by BA in BHK cells and only slight induction in D98 cells. In mouse-hamster hybrids treated with 13 μ M BA, AHH was induced in six of nine clones tested. AHH induction in these cells proceeded at levels comparable to those seen in parent 3T3 cells. In one clone with a 2S complement of mouse chromosomes, AHH induction proceeded at twice the level seen in 3T3 cells. The mouse-hamster cell hybrids which lacked BA-inducible AHH had a hamster chromosomal excess and/or deficiency of mouse chromosomes. BA-inducible AHH was seen in all of three hybrid clones of 3T3-D98 cells.

- 4410 REMOVAL OF BOUND CARCINOGEN DURING DNA REPAIR IN NONDIVIDING HUMAN LYMPHOCYTES. (E.) Lieberman, M. W. (Chester Beatty Res. Inst., London, England) and A. Dipple. *Cancer Res* 32:1855-1860, 1972.

Removal of alkylation products from the DNA of mammalian cells was studied in nondividing human lymphocytes damaged with 7-bromomethylbenz(a)anthracene, a carcinogenic alkylating agent that produces chemically stable products upon reaction with DNA. The reaction of 7-bromomethylbenz(a)anthracene-³H with cells in lymphocyte culture was complete in about 20 min. The unlabeled compound induced unscheduled (repair) DNA synthesis in lymphocytes maintained in hydroxyurea, and this process was complete in about 12 hr. The DNA of cells treated with the radioactive bromo- compound (1 μ M) exhibited a 15 to 17% loss of radioactivity in 12 hr, while exposure to a higher concentration of the agent (20 μ M) resulted in an 8 to 9% loss of radioactivity. Salmon sperm DNA alkylated by this agent exhibited no detectable loss of radioactivity after heating for 22 hr at 50 C. The major sites of attack of 7-bromomethylbenz(a)anthracene on lymphocyte DNA were the amino groups of guanine and adenine. Analysis of DNA isolated from treated lymphocytes at zero time and 12 hr later suggested that the damaged adenine nucleotides were removed more extensively than were the damaged guanine nucleotides and that participation in the cell cycle is not a precondition for removal of bound carcinogen.

- 4411 THE INFLUENCE OF PHYSOSTIGMINE ON THE ACTIVATION OF METHYLAZOXYMETHANOL ACETATE, A POTENT CARCINOGEN, BY A SERUM FACTOR *IN VITRO*. (E.) Poynter, R. W. (Sch. Med., Leeds, England), C. R. Ball, J. Goodban and T. Thackrah. *Chem Biol Interact* 4(2):139-143, 1972.

The effect of methylazoxymethanol (MAMAc), a chemically stable potent carcinogen, was studied using ³H-thymidine (³H-TdR) incorporation into DNA of cultured HeLa cells. Preincubation of MAMAc in medium containing 7% fetal calf serum at 37 C enhanced its ability to inhibit ³H-TdR uptake. The enhancing effect increased with increasing incubation time up to a maximum of 90% inhibition at 20 hr. Activation of MAMAc was apparently due to a factor in the serum as MAMAc preincubated in medium without serum had no enhanced inhibitory effect on ³H-TdR incorporation into DNA. Deacetylation of MAMAc was necessary for activation. Preincubation of MAMAc with the specific cholinesterase inhibitor physostigmine (3 x 10⁻⁵ M) indicated that this enzyme was involved. It was concluded that deacetylation by fetal calf serum cholinesterase was the initiating step in activation of MAMAc and that such a mechanism may be responsible for the *in vivo* activation of this carcinogen.

- 4412 PERINATAL CARCINOGENESIS BY URETHAN. (E.) Vesselinovitch, S. D. (Pritzker Sch. Med., U. Chicago, Ill.), N. Mihailovich, K. V. N. Rao and L. Itze. *Cancer Res* 31:2143-2147, 1971.

The neoplastic response following prenatal and/or neonatal exposure of (C57BL x C3H)F₁ mice to urethan was studied. Pregnant C57BL females received i.p. injections of urethan (0.5 mg/g body wt/dose) either daily (11th to 15th or 14th to 18th gestation days) or at three-day intervals (12th, 15th, and 18th day of gestation). Some pre-exposed neonates received two, three or five additional carcinogen injections. Animals were sacrificed at 48 wk of age and examined for tumors. Animals which had five daily intra-uterine urethan exposures developed hepatomas, lung adenomas, ovarian adenomas and granulosa cell tumors, and Harderian gland cystadenomas. A difference in sex response was seen only with liver tumors, where males had a higher incidence than females. The incidence of liver and lung tumors was significantly increased in animals exposed to urethan late in gestation. Combination of five prenatal and three or five postnatal urethan administrations produced a higher incidence of hepatomas, lung adenomas, ovarian tumors, and Harderian gland cystadenomas than did prenatal treatment alone or postnatal treatment alone. In addition, neonatal treatment with three or five doses of urethan produced malignant lymphocytic lymphomas involving the thymus.

- 4413 EFFECT OF CALCIUM CHROMATE DUST, INFLUENZA VIRUS, AND 100 R WHOLE-BODY X RADIATION ON LUNG TUMOR INCIDENCE IN MICE. (E.) Nettesheim, P. (Oak Ridge Natl. Lab., Tenn.) M.G. Hanna Jr., D. G. Doherty, R. F. Newell and A. Hellman. *J Nat Cancer Inst* 47(5):1129-1144, 1971.

Chronic inhalation exposure (five hr/day, five days a week for life) of C57BL/6 mice to calcium chromate (CaCrO_4) dust resulted in a fourfold increase in pulmonary adenoma incidence over that seen in filtered-air controls. Acute exposure to 100 R whole-body X radiation caused a similar increase in tumor incidence. The effects of the two tumorigenic insults were not additive. PR8 influenza virus infection suppressed spontaneous as well as X ray- and CaCrO_4 -induced pulmonary adenoma development. The overall lung adenoma incidence was higher in males than in females. CaCrO_4 also induced other pathological changes in the respiratory tract, such as epithelial necrosis and regenerative hyperplasia in the conducting airways, alveolar "bronchiolization," alveolar proteinosis, and emphysema-like changes, and suppressed the lymphoma incidence.

- 4414 RECIPROCAL RELATIONSHIP BETWEEN THE PRODUCTION OF ADRENAL DAMAGE BY 7,12-DIMETHYLBENZ(a)ANTHRACENE IN RATS AND THE INDUCTION OF LIVER DAMAGE BY VARIOUS TREATMENTS. (E.) Wheatley, D. N. (U. Med. Bldgs., Aberdeen, Scotland), M. E. Gerrard, I. R. Kernohan and A. R. Currie. *Brit J Cancer* 26: 99-107, 1972.

Carbon tetrachloride (CCl_4) (0.3 ml) was injected i.p. into rats before and after they received i.v. 3 mg of 7,12-dimethylbenz(a)anthracene (DMBA). Three days after DMBA administration, rats were killed and livers and adrenal glands were examined. CCl_4 protected rats against DMBA adrenocorticolysis when injected less than one hr before DMBA; no protection was afforded by CCl_4 after DMBA. DMBA given one hr before CCl_4 protected rats against lethal liver damage; this protection implied a reduction of CCl_4 hepatotoxicity. Evidently, the hepatotoxicity of CCl_4 was related reciprocally to the adrenocorticolytic effect of DMBA. *p*-Dimethylaminoazobenzene (DAB) injected into rats seven days before to one day after DMBA protected against DMBA's adrenal action when DAB was given from 3 hr to two days before DMBA, but did not protect when given after DMBA. Prior exposure of rats to DMBA potentiated the hepatotoxic effects of DAB. Partial hepatectomy of rats protected against DMBA adrenocorticolysis when livers were operated on from four to one day before DMBA. Partial hepatectomy also protected rats against DMBA when livers were partially removed 6 to 24 hr after DMBA.

- 4415 PATTERN OF 2-METHYL-4-DIMETHYLAMINOAZOBENZENE-BINDING PROTEINS IN THE LIVERS OF PARTIALLY HEPATECTOMIZED RATS AND OF CONTINUOUSLY DYE-FED RATS IN COMPARISON WITH 3'-METHYL-4-DIMETHYLAMINOAZOBENZENE. (E.) Sugimoto, T. (Zool. Inst., Fac. Sci., U. Tokyo, Japan) and H. Terayama. *Cancer Res* 32:1878-1883, 1972.

Partially hepatectomized and sham-operated rats received 2-methyl-4-dimethylaminoazobenzene (2-Me-DAB) in a single dose (10 mg) and normal rats were fed a diet containing 0.06% 2-Me-DAB for 2-week and 1-month periods. The patterns of dye-binding proteins in the cytosols prepared from the livers of these rats were

investigated by chromatography on carboxymethylcellulose as well as by gel filtration in Sephadex G-100, and the results were compared with those of rats given 3'-methyl-4-dimethylaminoazobenzene (3'-Me-DAB) under the same conditions. It was found that 2-Me-DAB given in a single dose is preferentially bound to the slightly basic protein fractions (Fractions IV and VI) in sham-operated rats but to the nonbasic protein fraction (Fraction I) in partially hepatectomized rats, while 3'-Me-DAB is preferentially bound to Fraction I in both cases. Gel filtration of Fraction I revealed that 3'-Me-DAB is preferentially bound to the higher-molecular weight subcomponent (I-a) in both sham-operated and partially hepatectomized rats, while 2-Me-DAB is bound to the smaller-molecular-weight subcomponent (I-b) in the sham-operated rat liver but to I-a in the regenerating liver. For Fraction IV, 3'-Me-DAB is bound to the higher-molecular-weight subcomponent (IV-a) in sham-operated rats but to the lower-molecular-weight subcomponents (IV-b,c) in partially hepatectomized rats, while 2-Me-DAB is bound to the lower-molecular-weight subcomponents in both sham operated and partially hepatectomized rats. The results support a previous finding that dye binding to I-a target protein may be involved in chemical carcinogenesis.

- 4416 β -GLUCOSIDASE MODULATION IN PREWEANLING RATS AND ITS ASSOCIATION WITH TUMOR INDUCTION BY CYCASIN. (E.) Matsumoto, H. (Dept. Agricultural Biochem., U. Hawaii, Honolulu), Y. Nagata, E. T. Nishimura, R. Bristol and M. Haber. *J Nat Cancer Inst* 49(2):423-434, 1972.

Cycasin, an azoxy- β -glucoside, induces tumor growth when injected into developing but not mature rats. The active principle has been demonstrated to be the aglycone, methylazoxymethanol (MAM). Changes in β -glucosidase activity, therefore, were determined in tissues of various organs of preweanling Wistar strain rats. The enzyme activity of the small intestine increased gradually to a maximum around the 15th postnatal day and decreased rapidly to a minimum shortly after the weanling age of 21 days. There was comparatively little β -glucosidase activity in other tissues. Cycasin injected into growing rats did not modify the β -glucosidase activity of the various tissues. The enzyme activity in none of the tissues was affected by the nature of the substrate--either by the natural glucoside, cyasin, or the synthetic glucoside, *p*-nitrophenyl- β -D-glucoside. A single dose of cycasin, 1 mg/g body weight, administered s.c. or i.p. in Wistar rats between ages of 5-20 days induced a moderately high incidence of neoplasms after approximately 208 days. Subcutaneous inoculation of rats at 25 days of age, with an identical amount of cycasin, failed to initiate the tumor development. The incidence of tumors induced appeared to correlate well with the modulation of β -glucosidase activity in the intestinal mucosa of maturing rats. Most neoplasms induced by cycasin, had the characteristics of mesenchymal tumor of the kidney. A moderately high incidence of renal adenocarcinomas was also present, but hepatic malignancies were not frequent. The appearance of mesenchymal tumor is age related

and the peak of susceptibility coincides with the maximum β -glucosidase activity.

- 4417 EQUILIBRIUM CENTRIFUGATION STUDIES OF COLON DNA FROM MICE TREATED WITH THE CARCINOGEN 1,2-DIMETHYLHYDRAZINE. (E.) Hawks, A. (Middlesex Hosp. Med. Sch., London, England), E. Farber and P. N. Magee. *Chem Biol Interact* 4(2):144-148, 1972.

The chemical carcinogen 2-fluorenylacamide (FA) was shown by other investigators to be bound to glycogen and DNA of FA-induced hyperplastic rat liver nodules several weeks after its removal from the diet. To determine if this phenomenon applied to other organs and other carcinogens, DNA of 1,2-dimethylhydrazine (DMH)-induced colonic and rectal mouse tumors was analyzed by CsCl equilibrium density centrifugation. No minor DNA component in DMH-induced colonic nodules had a density of 1.73 g/cm³, as had been reported for FA-induced hyperplastic nodules. Analysis of liver DNA from mice injected with DMH also failed to demonstrate this minor peak, although an amylase-sensitive peak banding at a density of 1.68 g/cm³ was detected. It was concluded that the results obtained with FA cannot be generalized to include all forms of neoplasia.

- 4418 DIETARY AFLATOXINS AND HUMAN LIVER CANCER. IV. INCIDENCE OF PRIMARY LIVER CANCER IN TWO MUNICIPAL POPULATIONS OF THAILAND. (E.) Shank, R. C. (Dept. Nutr., Massachusetts Inst. Tech., Cambridge), N. Bhamarapravati, J. E. Gordon and G. N. Wogan. *Fd Cosmet Toxicol* 10(3):171-179, 1972.

Field studies were conducted to determine the possible relation between food-borne mycotoxins, particularly the aflatoxins, and primary liver cancer among certain populations in Thailand. According to a diet survey conducted over a one-yr period (mid-June 1969 to mid-June 1970), villagers in the Province of Ratburi ingested an average of 45-77 ng total aflatoxins/kg body wt daily, while the value found for the Province of Songkhla was 5-8 ng/kg/day. Epidemiologic investigations on the occurrence of primary liver cancer were performed coincident with the diet studies in urban areas of these two provinces. Primary liver cancer incidence in the Songkhla area was found to be approximately the same as in the eastern United States and northwestern Europe, whereas the incidence was three to six times greater in the Ratburi area, in both urban and rural populations. Thus the consumption of aflatoxins appears to have had a direct relationship to the occurrence of primary liver cancer in these regions of Thailand.

- 4419 DETECTION OF ACTIVATING ENZYMES FOR 4-NITROQUINOLINE 1-OXIDE ACTIVATION WITH A MICROBIAL ASSAY SYSTEM. (E.) Fukuda, S. (Temple U. Sch. Med., Philadelphia, Pa.) and N. Yamamoto. *Cancer Res* 32(2):435-439, 1972.

4-Nitroquinoline 1-oxide (4NQO) has been shown to

inactivate the DNA repair-deficient mutants, *her*- and *recA*, of *Salmonella typhimurium* to a much greater extent than the wild-type cell. Bacteriophage P22 was insensitive to 4NQO but was rapidly inactivated by 4-hydroxyamino-quinoline 1-oxide (4HAQO), a reduction product of 4NQO. These results implied that *S. typhimurium* could convert 4NQO to 4HAQO and that 4HAQO was reacting with the genomes. When phage P22 was treated with (4HAQO) (10⁻⁶M) and assayed on *S. typhimurium* strains lysogenic for P221, a rapid inactivation of P22 (30 min.) and a greatly increased frequency of recombination between P22 and the prophage P221 were observed. This phage assay system was used to search for either activating enzymes which convert 4NQO to 4HAQO or a reactive intermediate substance that inactivates bacteriophage. When fractions from bacterial homogenates separated by diethylaminoethyl (DEAE)-cellulose were incubated with 4NQO, BADG and bacteriophage P22C₂, one sharp peak was found which could inactivate the bacteriophage. The fractions from bacterial homogenates were also analyzed for 4NQO reducing and diaphorase activities. The peak showing both activities was found to correspond to the peak for phage inactivation. Samples from the incubation mixture containing 4NQO, NADH, and P22C₂ produced the same effects in the phage assay system as had previously been observed for 4HAQO. It was therefore concluded that the bacterial diaphorase converted 4NQO to 4HAQO and that 4HAQO reacted with the phage genome. Experiments with rat liver cytosol fractions showed that there were two peaks eluting from DEAE-cellulose which could activate 4NQO and which also possessed diaphorase activity.

- 4420 MAMMARY TUMORIGENESIS BY SUBCUTANEOUS ADMINISTRATION OF A MIXTURE OF MEGESTROL ACETATE AND ETHYNYLESTRADIOL IN WISTAR RATS. (E.) Hisamatsu, T. (Sch. Med., Showa U., Tokyo, Japan). *Gann* 63(4):483-485, 1972.

The carcinogenic activity of an 8:1 mixture of megestrol acetate, a synthetic progesterone, and ethynylestradiol, a synthetic estrogen, was studied. Female Wistar strain rats received s.c. injections of 5, 10 or 15 mg/kg of the mixture once every other day for 30 days. Two of ten rats receiving 5 mg, four of eight rats receiving 10 mg, and two of nine rats receiving 15 mg, developed one or two mammary fibroadenomas per animal between 240 and 320 days after the start of the experiment. None of ten control animals developed tumors.

- 4421 STUDIES ON *AGROBACTERIUM TUMEFACIENS*: CONDITIONS FOR MUTAGENESIS BY *N*-METHYL-*N'*-NITRO-*N*-NITROSO-GUANIDINE AND RELATIONSHIPS OF *A. TUMEFACIENS* MUTANTS TO CROWN-GALL TUMOR INDUCTION. (E.) Langley, R. A. (Dept. Plant Pathol., U. California, Davis) and C. I. Kado. *Mutat Res* 14(3):277-286, 1972.

Agrobacterium tumefaciens were exposed to up to 500 μ g/ml *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine at pH 5.0-7.5 for three hr; induced mutants were tested

for ability to induce crown-gall tumor on sunflower. Optimum mutant induction by nitrosoguanidine was seen at 250 µg/ml at pH 6.5. Antibiotic-resistant mutants of *A. tumefaciens* and amino acid auxotrophs were tested on sunflower. All of the selected antibiotic-resistant mutants (resistant to neomycin, kanamycin and rifampicin) were as virulent as wildtype *A. tumefaciens* in inducing crown-gall tumors. This indicated that mutations conferring resistance to antibiotics did not directly affect tumorigenic virulence of *A. tumefaciens*. Mutants resistant to neomycin were also resistant to kanamycin and *vice versa*. Amino acid auxotrophs obtained by nitrosoguanidine treatment showed varying degrees of virulence on sunflower. Some auxotrophs requiring histidine, leucine or tryptophan had lost their virulence. Nonvirulent auxotrophs, when supplemented with the required amino acid, grew *in vivo* nearly as well as prototrophic *A. tumefaciens*; this indicated that the alteration of virulence of *A. tumefaciens* did not depend on the growth of the organism.

4422 INDUCTION OF TUMORS IN THE BRAIN, KIDNEY, AND OTHER EXTRA-MAMMARY GLAND ORGANS BY A CONTINUOUS ORAL ADMINISTRATION OF N-NITROSOBUTYLUREA IN WISTAR/FURTH RATS. (E.) Takizawa, S. (Res. Inst. Nuclear Med. Biol., Hiroshima U., Japan) and H. Nishihara. *Carcin* 62(6):495-503, 1971.

A continuous oral administration of N-nitrosobutylurea (NBU) for six months induced a variety of tumors besides mammary tumors in variously conditioned Wistar/Furth (W/Fu) rats of both sexes. The animals were castrated before the NBU treatment or castrated and supplemented with biweekly injections of 0.4 mg of progesterone and 0.01 mg of estradiol benzoate or with an ovarian graft under the kidney capsule. Leukemias of myeloid and undifferentiated-cell types developed in even rats with a mean latent period of 237±37 days, kidney tumors mostly of the so-called nephroblastoma and clear-cell carcinoma in eight rats with a latent period of 289±34 days, and brain tumors in 14 rats, mostly oligodendrogliomas except one case of ependymoma, with a latent period of 320±21 days, out of 64 rats. In a few rats, tumors of the thyroid, liver, caecum, duodenum, and peripheral nerve were found. No evidence has been obtained of hormonal implications in the genesis and progression of the afore-mentioned tumors other than mammary tumors.

4423 TUMORIGENESIS BY CADMIUM. (E.) Lucis, O. J. (Dept. Path., Dalhousie U., Halifax, N.S., Canada), R. Lucis and K. Aterman. *Oncology* 6:53-67, 1972.

Male Wistar rats were injected s.c. or in the liver with $^{109}\text{CdCl}_2$ or $^{65}\text{ZnCl}_2$. The highest amounts of radioactive Cd were distributed in liver, kidney, pancreas and spleen; no tumors developed in these organs. However, ^{109}Cd was also found in testes, which did develop tumors. After one s.c. injection

of $^{109}\text{CdCl}_2$, skin at the area of injection showed a high ^{109}Cd concentration; liver did not retain ^{109}Cd at the injection site after intrahepatic injection. ^{109}Cd in testes reached maximum concentrations within six hr after injection, while ^{65}Zn was deposited in testes continuously for at least 20 days. Twenty-four hr after s.c. injection of unlabeled CdCl_2 (0.02-0.03 mM/kg), testes showed necrosis of seminiferous tubules. By 48 days, marked proliferation in interstitial cells in testes was seen, and by 11 months, testes of all animals were fibrosed and contained nodules of interstitial cells. Fibrosarcoma developed at the s.c. injection sites in two cases.

4424 METABOLISM OF POLYCYCLIC AROMATIC HYDROCARBONS IN CELL CULTURES. (E.) Huberman, E. (Med. Sch., U. Wisconsin, Madison), J. K. Selkirk and C. Heidelberger. *Cancer Res* 31:2161-2167, 1972.

Transformed and untransformed mouse prostate cells were treated with tritiated 3-methylcholanthrene (MCA), benzo(a)pyrene, 9,10-dimethyl-1,2-benzanthracene, 1,2,5,6-dibenzanthracene or 1,2,3,4-dibenzanthracene and maintained under conditions favoring malignant transformation. The metabolism of the polycyclic aromatic hydrocarbons to water- and organic-soluble products was observed. The amount of conversion of MCA to water-soluble metabolites was proportional to cell number in both exponentially growing and contact-inhibited cells. MCA metabolism to water-soluble products increased with time and was proportional to the amount of MCA up to 10^3 - 10^4 µmoles/ 3×10^6 cells. Above this dose level, increased dose did not produce increased rates of water-soluble metabolite production. The highest production of water-soluble metabolites was obtained from benzo(a)pyrene and the lowest from 1,2,5,6-dibenzanthracene. Susceptibility of cells to the cytotoxic effects of MCA was closely correlated with amount of water-soluble metabolite production. The major metabolites from 1,2,5,6-dibenzanthracene were dihydrodiols; from 9,10-dimethyl-1,2-benzanthracene, dihydrodiols and hydroxymethyl derivatives predominated. Phenols were produced in smaller amounts from both these compounds.

4425 CARCINOGENESIS IN PULMONARY EPITHELIA IN MICE ON DIFFERENT LEVELS OF VITAMIN A. (E.) Smith, W. E. (Hlth. Res. Inst., Fairleigh Dickinson U., Madison, N.J.), E. Yazdi and L. Miller. *Environ Res* 5(9):152-163, 1972.

Lungs from 82 fetal or neonatal BALB/c mice were minced and implanted with 20-methylcholanthrene (MCA) into the right posterior thigh muscles of adult male BALB/c mice. Bronchial, bronchiolar or alveolar-like structures developed at implant sites. Squamous cell carcinomas arose in 9 of 56 mice maintained on an adequate diet supplemented by vitamin A, in 4 of 58 given an adequate diet without supplementary vitamin A, but in none of 25 given a diet deficient in vitamin A. The first tumor was found 64 days after lung cell-MCA implantation; it developed in a mouse on the adequate diet. With the lowest MCA dose (0.01M) there were many adenocarcinomas and a few poorly differen-

tiated squamous cell carcinomas. Well-differentiated carcinomas developed with larger MCA doses (0.02 and 0.04 M).

- 4426 DNA REPAIR FOLLOWING EXPOSURE OF HUMAN LYMPHOCYTES TO 4-NITROQUINOLINE-1-OXIDE. (E.) Jacobs, A. J. (U. Southern California Sch. Med., Los Angeles), R. L. O'Brien and P. Paolilli. *Int J Cancer* 10:118-127, 1972.

Human lymphocytes were treated with UV radiation (70 ergs/mm²) in the presence of varying concentrations of hydroxyurea (HU). Uptake of ³H-thymidine by these lymphocytes was observed as a measure of DNA replicative synthesis. ³H-thymidine uptake was suppressed in HU-treated, UV-exposed lymphocytes; suppression was proportional to HU concentration. When lymphocytes were treated with 4-nitroquinoline-1-oxide (4-NQO) instead of UV, unscheduled DNA synthesis increased with exposure to up to 10⁻⁵ M 4-NQO; at higher concentrations, DNA synthesis appeared to be suppressed. Replicative DNA synthesis was suppressed in 4-NQO-treated cultures, at all 4-NQO concentrations. In related experiments, human lymphocytes were treated with phytohemagglutinin-M and bromodeoxyuridine (BUDR); BUDR was taken up by DNA in replicative synthesis. Following BUDR treatment and incorporation, BUDR was removed and cells were treated with 4-NQO and ³H-thymidine. DNA from these cells was fractionated by cesium chloride gradient centrifugation into a BUDR-containing fraction of replicated DNA and a light DNA fraction. The heavy fraction of DNA from 4-NQO-treated cells, fraction devoid of replicated DNA, contained ³H-thymidine. This was thought to represent repair DNA synthesis.

- 4427 THE RELEVANCE OF CHEMICO-BIOLOGICAL INTERACTIONS FOR THE TOXIC AND CARCINOGENIC EFFECTS OF AROMATIC AMINES. V. THE PHARMACOKINETICS OF RELATED AROMATIC AMINES IN BLOOD. (E.) Groth, U. (Max-Planck Inst., Munich, West Germany) and H.-G. Neumann. *Chem Biol Interact* 4:409-419, 1972.

Male and female Wistar rats were studied for the distribution of radioactivity after single or repeated administration of 1.2 or 1.5 mg of ³H-labeled *trans*-4-dimethylaminostilbene (*trans*-DAS), *cis*-4-dimethylaminostilbene (*cis*-DAS), and 4-dimethylaminobenzyl (DABB). Total blood radioactivity, radioactivity bound to plasma proteins, and radioactivity bound to red cell constituents were determined from 5 to 216 hr after stomach feeding of the compounds. *Trans*-DAS produced higher levels of blood radioactivity than the other two compounds (e.g., 5 hr after *trans*-DAS feeding, total blood radioactivity was 12.9 nmole/g blood compared with 5.2 and 7.0 nmole/g blood 5 hr after feeding with *cis*-DAS and DABB, resp.). The higher levels induced by *trans*-DAS were due to enhanced binding of metabolites, primary to hemoglobin. Gel-filtration experiments indicated that radioactivity was bound to plasma proteins, predominantly albumin, to a comparable degree a few hours after administration of all three compounds. Part of the *trans*-stilbene activity and most of the *cis*-stilbene

and dibenzyl activity was loosely bound and removable by extraction with organic solvents. Erythrocytes contained considerably more radioactivity after administration of *trans*-DAS. On gel filtration most of the radioactivity migrated with hemoglobin and was only partly extractable with organic solvents. The decrease in red cell radioactivity appeared to be related to the life span of red cells. The pattern of unbound plasma metabolites analyzed by radio gas chromatography was similar to that in the liver and kidney, but differed from that in erythrocytes. Of the metabolites extracted from hemoglobin, *trans*-acetylaminostilbene and *trans*-aminostilbene had the highest affinity for hemoglobin.

- 4428 DIETHYL PYROCARBONATE: FORMATION OF URETHAN IN TREATED BEVERAGES. (E.) Löfroth, G. (Wallenberg Lab., Stockholm, Sweden) and T. Gejvall. *Science* 174(4015):1248-1250, 1972.

The antimicrobial food additive diethyl pyrocarbonate (DEP) was labeled with tritium and added in amounts of 250 or 500 µl/l to orange juice, white wine or beer. In isotope dilution analyses with the labeled DEP, addition of 250 µl/l of DEP to orange juice resulted in the formation of 0.2 mg carcinogenic urethan, while addition of 500 µl/l DEP to white wine or beer resulted in the formation of 1-3 mg/l urethan.

- 4429 BENIGN BREAST DISEASE IN WOMEN ON ESTROGEN THERAPY: A PATHOLOGIC STUDY. (E.) Fechner, R. E. (Baylor Coll. Med., Houston, Tex.). *Cancer* 29(2):273-280, 1972.

Microscopic examinations were performed on breast tissue from 41 women with fibrocystic disease (FCD) and two with fibroadenoma; all patients had been taking estrogens. Breast tissues from 41 women with FCD who were not on estrogens were also examined. Heterogeneous tissue changes in the breasts of FCD women on estrogens were qualitatively indistinguishable from those in women not on estrogens. Apocrine metaplasia was slightly more common in the hormone-treated group. Breasts with severe hyperplasia tended to be concentrated in the 36-45 yr age range in hormone-treated patients; severe hyperplasia was more evenly distributed among various ages in non-hormone-treated patients. Thirty-nine percent of hormone-treated patients had epithelial hyperplasia compared to 32% of nonhormone-treated patients; this difference was not statistically significant.

- 4430 ON THE CORRELATION BETWEEN THE HEPATOCARCINOGENICITY OF THE CARCINOGEN, *N*-2-FLUORENYLACETAMIDE, AND ITS METABOLIC ACTIVATION BY THE RAT. (E.) Gutmann, H. R. (VA Hosp., Minneapolis, Minn.), D. Malejka-Giganti, E. J. Barry and R. E. Rydell. *Cancer Res* 32:1554-1561, 1972.

Female Sprague-Dawley rats and female Fischer 344

rats were injected i.p. with 2.3 mg/100 g *N*-2-fluorenylacetylamide (2-FAA) three times/wk for 1 month. 2-FAA produced mammary adenocarcinomas in 92% of Sprague-Dawley rats but produced no tumors in Fischer rats. When tracer methods were used to measure the biliary excretion of *N*-hydroxy-2-FAA-¹⁴C, it was found that Sprague-Dawley rats excreted 25% of the 2-FAA as *N*-hydroxy-2-FAA-¹⁴C, while only 1-2% of a similar dose of 2-FAA-¹⁴C was excreted as the *N*-hydroxy metabolite by Fischer rats. *N*-hydroxy-2-FAA administered to Fischer rats by the same schedule that had been ineffective with 2-FAA caused a high incidence of liver tumors. Susceptibility to *N*-hydroxy-2-FAA carcinogenesis coincided with the extent of sulfonation of the hydroxyamino acid by hepatic arylsulfotransferase *in vivo* and *in vitro*. This enzyme was low in Sprague-Dawley rats, which were refractory to *N*-hydroxy-2-FAA hepatocarcinogenesis, and high in Fischer rats.

4431 RAPID INDUCTION OF BLADDER CANCER IN RATS WITH *N*-METHYL-*N*-NITROSOUREA. I. HISTOLOGY. (E.) Hicks, R. M. (Middlesex Hosp. Med. Sch., London, England) and J. St. J. Wakefield. *Chem-Biol Interact* 5(2):139-152, 1972.

Rats were given *N*-methyl-*N*-nitrosourea (MNU) as a single 2 mg dose injected into the bladder. Though no tumors developed, bladder epithelium showed basal cell necrosis and stripping of epithelium within two days after treatment. Stripped areas regenerated rapidly and hyperplasia was seen within 2-8 wk. A single dose of 3 mg MNU by urethral catheter was lethal. Four 1.5 mg doses, given by urethral catheter over a 6 wk period, were not lethal but produced bladder carcinomas in all rats kept for 30 wk. In these rats, early bladder changes included necrosis, stripping of epithelium and hyperplastic regrowth. Papillomas formed in bladder by 12 wk after MNU. Epithelial cells diverged more widely from the normal cell type in rats given a total of 6 mg MNU than in rats given one 2 mg dose. Squamous metaplasia was apparent by 4 wk after 6 mg MNU. Squamous cell tumors developed as squamous cells invaded the bladder's muscle wall. Carcinomas appeared by 12 wk.

4432 EFFECT OF PAPAIN ON THE CARCINOGENESIS BY *P*-DIMETHYLAMINOAZOBENZENE (DAB). (E.) Ambara, T. (Kumamoto U. Med. Sch., Japan), T. Ogata and G. Tokaji. *Kumamoto Med J* 24(3-4):124-134, 1971.

Male Wistar rats were fed *p*-dimethylaminoazobenzene (DAB) or a carcinogen-free diet for 77-83 days. When DAB doses totaled approximately 500 mg, one group of rats (A) was given 25 weekly i.p. injections of 0.25 ml papain solution/100 mg body wt; the other DAB-fed rats (group B) were not given papain. Rats not fed DAB (group C) were also given papain. Papain did not affect the final rate of liver tumor formation in DAB-fed rats but appeared to accelerate tumor formation in its early stages. The mitotic index of liver

cells of group A rats after a single injection of papain was 977 cells in mitosis/100,000 cells compared with 28 mitoses/100,000 cells in group B rats given no papain. Papain without DAB induced no tumors. There were no significant differences between group A and B rats with regard to tumor incidence in each lobe of the liver or to sites of metastasis of liver tumors.

4433 POLYCYCLIC HYDROCARBON-PRODUCED TOXICITY, TRANSFORMATION, AND CHROMOSOMAL ABERRATIONS AS A FUNCTION OF ARYL HYDROCARBON HYDROXYLASE ACTIVITY IN CELL CULTURES. (E.) Benedict, W. F. (Nat'l. Inst. Child Hlth. Human Development, Nat'l. Inst. Hlth., Bethesda, Md.), J. E. Gielen and D. W. Nebert. *Int J Cancer* 9(2):435-451, 1972.

Rat hepatoma tissue culture cells (HTC), mouse L cell derivatives (A9), HeLa cells, fetal rat hepatocytes and fetal hamster secondary cells were treated with benzo(a)pyrene (BP), 3-hydroxybenzo(a)pyrene or 7,12-dimethylbenz(a)anthracene (DMBA) for 24 hr. Cytotoxicity, cell transformation and chromosome abnormalities were observed in cultures treated with the three polycyclic hydrocarbons; hydrocarbon treatment was in some cases combined with treatment with α -naphthoflavone (ANF) or phenobarbital. BP (1 μ g/ml) was toxic to rat hepatocytes; this effect was prevented by phenobarbital or ANF. BP was not toxic to HTC, A9 or HeLa cells, which contain little or no aryl hydrocarbon hydroxylase (AHH) activity. However, BP was toxic to HTC, A9 and HeLa cells grown with fetal rat hepatocytes in the presence of phenobarbital (fetal rat cells had high levels of basal and benz(a)anthracene-(BA)-inducible AHH). A correlation between chromatid breakage and cytotoxicity was evident in fetal hamster cells and in HeLa cells treated with BP, 3-hydroxybenzo(a)pyrene or DMBA. Aneuploidy was seen in hydrocarbon-treated hamster fetal cell cultures in which there were transformed foci but no toxicity or chromatid breaks. This finding suggests that aneuploidy is more closely associated with malignant transformation than is chromosomal breakage, while chromosomal breakage is related to cytotoxicity. BA or ANF competitively inhibited the hydroxylation of DMBA or BP. Transformation was never observed in fetal hamster secondary cells exposed to DMBA plus excessive amounts of BA. This suggests that BA or its metabolites may prevent a specific effect by which DMBA or a DMBA metabolite causes cell transformation.

4434 CELL LOSS AND PROLIFERATION INDUCED BY *N*-2-FLUORENYLACETAMIDE IN THE RAT LIVER IN RELATION TO HEPATOMA INDUCTION. (E.) Albert, R. E. (New York U. Med. Ctr., New York), F. J. Burns, L. Bilger, D. Gardner and W. Troll. *Cancer Res* 32(10):2172-2177, 1972.

Cell loss and replacement were examined in relation to tumor induction following various doses and ex-

posure patterns of the carcinogen *N*-2-fluorenylacetylamide (2-FAA) in the diet of male albino rats. In Experiment 1, the hepatic DNA was prelabeled by the injection of thymidine-³H (TdR-³H) into weanling animals, and the loss of the tritium activity was measured at various times after the start of the carcinogen treatment. In Experiment 2, single injections of TdR-³H were given at various times during continuous exposure to the carcinogen at levels of 0.03, 0.01, and 0.003%. The uptake of TdR-³H in hepatic DNA, the parenchymal cell-labeling index, and the total hepatic DNA were determined. In Experiment 3, the incidence of hepatic carcinoma was determined for various exposure durations to 0.03, 0.01, 0.003, and 0.001% 2-FAA. At 42 days after the start of administration of 0.03% 2-FAA, the uptake of TdR-³H in the hepatic DNA increased markedly. With 0.03% 2-FAA, the pulse labeling index increased progressively between 42 and 120 days, while the pulse labeling index for 0.01% 2-FAA showed no increase until 120 days. With 0.03% 2-FAA, the prelabeled DNA decreased markedly between 42 and 72 days, while the total hepatic DNA increased by about 15 to 20% by 72 days. The tumor data showed that a 365-day exposure to 0.01% 2-FAA was approximately equivalent to a 112-day exposure to 0.03% 2-FAA, i.e., an equivalent tumor yield for equal total doses. However, 28- and 56-day exposures to 0.03% 2-FAA were far less effective than 112-day exposures to 0.01% 2-FAA. The data suggest that, at 0.03%, the carcinogen produced an increase in the parenchymal cell replication rate that correlated with the tumor incidence and that, when the carcinogen was stopped early enough to prevent tumors, very little of the original DNA was lost and the replication rate of the parenchymal cells was only slightly increased.

- 4435 UTERINE AND MAMMARY NEOPLASIA AND OTHER CHANGES (AMYLOIDOSIS) IN C₃H MICE, RELATED TO OVARECTOMY, ESTROGEN AND METHYLCHOLANTHRENE. (E.) Wessely, Z. (Long Island Jewish Med. Ctr., Jamaica, N.Y.) and J. V. Klavins. *Oncology* 26:33-52, 1972.

Cords impregnated with 3-methylcholanthrene (MC) were inserted in the uteri of virgin C₃H mice; some mice were given s.c. injections of 50 µg estradiolbenzoate after MC, while others were castrated. Uterine tumor development was observed for 48 wk. Twenty-three of 82 mice given MC alone and 18 of 58 mice given estrogen after MC, developed cervical squamous carcinomas (difference not statistically significant). In castrated animals, tumor incidence was significantly less than in animals receiving estrogen but not significantly different from that in animals receiving MC alone (6 of 43 mice castrated after MC developed tumors). Tumor differentiation was better in estrogen-treated mice than in castrated mice. Dysplasia and hyperplasia were more common in MC- and estrogen-treated animals. Estrogen increased the PAS-positive material (probably neutral mucopolysaccharides) in endometrial stroma and the acid mucopolysaccharides in cervical subepithelial tissues. Mammary carcinomas and liver amyloidosis were also associated with estrogen treatments.

- 4436 CORRELATIONS BETWEEN CARCINOGENIC TRACE METALS IN WATER SUPPLIES AND CANCER MORTALITY. (E.) Berg, J. W. (Natl. Cancer Inst., Bethesda, Md.) and F. Burbank. *Ann NY Acad Sci* 199:249-264, 1972.

The product of the frequency of detection of trace metals in drinking water systems and the average detected metal concentration was determined for ten basin areas in the United States. Areas were ranked according to the size of this statistic and the rank order was compared with the rank order of the areas for mortality from 34 types of cancer. Positive correlations between trace metals in drinking water and cancer mortality were found in 28 cases, eight more than expected. The excess of positive correlations came mainly from cadmium (correlated with oral and pharyngeal cancer, esophageal cancer, breast cancer, intestinal cancer) and lead (correlated with intestinal cancer, kidney cancer, ovarian cancer, all leukemias). For chromium, cobalt and iron there were no positive correlations significant at the 5% level.

- 4437 ACUTE ULTRASTRUCTURAL EFFECTS OF BENZO(a)-PYRENE AND FERRIC OXIDE ON THE HAMSTER TRACHEOBRONCHIAL EPITHELIUM. (E.) Harris, C. C. (Natl. Cancer Inst., Bethesda, Md.), M. B. Sporn, D. G. Kaufman, J. M. Smith, M. S. Baker and U. Saffiotti. *Cancer Res* 31:1977-1989, 1971.

Tracheobronchial epithelial ultrastructural changes were studied in young adult male Syrian golden hamsters following intratracheal instillation of benzo(a)-pyrene or pyrene carried on ferric oxide particles. The acute cellular changes included focal replacement of the tracheobronchial columnar epithelium with pleomorphic cells which showed ultrastructural features characteristic of atypical squamous cells. Polylobulated nuclei and pleomorphic nucleoli were characteristically found after multiple instillations of benzo(a)pyrene-ferric oxide. Instillation of ferric oxide alone or the noncarcinogenic hydrocarbon, pyrene-ferric oxide, resulted in reversible basal cell hyperplasia. The atypical squamous cells induced by benzo(a)pyrene-ferric oxide were ultrastructurally similar to hyperplastic epithelial cells described in the bronchi of smoking dogs and neoplastic squamous cells described in human bronchogenic carcinoma.

- 4438 PRETUMOR CHANGES OF THE EPITHELIUM INDUCED BY TRANSPLACENTAL EFFECT OF NITROSOMETHYLUREA IN ORGAN CULTURES OF EMBRYONAL LUNG TISSUE OF MICE. (Rus.) Kolesnichenko, T. S. (Inst. Exp. Clin. Oncol., Acad. Med. Sci. USSR, Moscow). *Vopr Onkol* 17(11):68-75, 1971.

Characteristics of the transplacental effect of nitrosomethylurea on embryonal lung tissue of mice (BD-IX) in organ cultures were studied. Nitrosomethylurea (5 mg) was injected s.c. in mice begin-

ning from the 14-16th day of pregnancy up to a total dose of 20 mg. On the 19-20th day of pregnancy, the animals were killed to extract the lung from 12 embryos for organ cultures to be examined 7, 14, 21, 28, and 33 days from culturing. Experimental cultures were more viable *in vitro* than the control cultures. With the prolongation of the experiment, dystrophic changes increased in control cultures, while pretumor changes increased in experimental cultures. From the seventh day, morphological characteristics of control and experimental cultures diverged. One of the first changes was diffuse hyperplasia of the alveolar and bronchial epithelium, leading to extensive proliferation and local hyperplasia (17-33 days), pericapsular growths and isolated complexes of epithelial cells. Local proliferation sites were found in 61/416 (14.6%) cultures. Adenomatous changes observed in 88/416 (21.15%) reflect the transplacental carcinogenic effect of nitrosomethylurea.

- 4439 ALTERNATIVE WAYS OF THYMIDYLATE BIOSYNTHESIS IN MOUSE TUMORS WITH VARIED SENSITIVITY TO 5-FLUOROURACIL. (Rus.) Meiren, D. V. (Inst. Exp. Clin. Oncol., Acad. Med. Sci. USSR, Moscow) and A. K. Belousova. *Biokhimiia* 36(6):1210-1216, 1971.

Biosynthesis of thymidylate as affected by 5-fluorouracil was studied in 5-fluorouracil-sensitive La leukemia cells and their stable variant La/FU, and in 5-fluorouracil-stable Ehrlich's ascitic tumor cells. The short-term incubation medium was Krebs-Ringer phosphate buffer with 0.1% glucose and the long-term medium was Eagle's medium with glutamic acid, 10% bovine serum and antibiotics. Both media contained C^{14} -formate and C^{14} -thymidine in concentrations $1 \cdot 10^{-6}$ - $5 \cdot 10^{-5}$ M and 5-fluorouracil in concentrations $1 \cdot 10^{-6}$ - $1 \cdot 10^{-3}$ M. In short-term incubation (one hr) with C^{14} -formate and C^{14} -thymidine, La and La/FU leukemia cells incorporated both precursors in DNA thymine two to three times more intensively than Ehrlich's ascitic tumor cells. Under these conditions, the biosynthesis of thymidylate from thymidine was greater in all tumor cells studied than the biosynthesis from desoxyuridylic acid. On the other hand, in view of the low concentration of endogenic thymidine, synthesis of thymidylate from thymidine did not occur and DNA thymine was mainly synthesized from desoxyuridylic acid in long-term (24 hr) incubation. Fluorouracil in a concentration of $1 \cdot 10^{-5}$ M and higher suppressed synthesis of DNA thymine from desoxyuridylic acid. The 5-fluorouracil concentration should be increased 100 times ($1 \cdot 10^{-3}$ M) to suppress such synthesis in La/FU leukemia cells. Incorporation of C^{14} -formate into DNA thymine (synthesis of thymidylate from desoxyuridylic acid) in Ehrlich's ascitic carcinoma cells with the same concentration (10^{-3} M) of 5-fluorouracil was inhibited only by 70%. There was a correlation between the sensitivity of the tumors to pyrimidine analogs and the degree of suppression of biosynthesis of thymidylate from desoxyuridylic acid under the influence of 5-fluorouracil.

- 4440 BIOANTIOXIDANTS VIEWED AS REGULATORS OF FREE-RADICAL OXIDATION PROCESSES OCCURRING AT DIFFERENT STAGES OF HEPATOCARCINOGENESIS. (Ukr.) Sydoryk, Ye. P. (Inst. Oncol. Prob. Ukrainian SSR Acad. Sci., Kiev, USSR), T. M. Yurkivs'ka and Ye. A. Bahley. *Ukr Biokhim Zh* 44(3):365-368, 1972.

Liver lipid antioxidant activity (AOA) and free radical oxidation processes were studied during different stages of 4-dimethylaminoazobenzene (4-DAB)-induced hepatocarcinogenesis in male mongrel rats. Two-months-old rats received 12 mg of 4-DAB in their daily rice diet, while a related control group received 4-aminoazobenzene (4-AB), a noncarcinogenic azo-compound. Lipids were extracted from liver homogenates prepared at different histomorphologically defined stages of the disease and AOA was evaluated according to the inhibition of the methylolate oxidation rate. Decreased AOA (from 2000 to below 1000 conventional U) was ascertained in both experimental and control animals two to four wk after beginning of the experiment. Increases in AOA appeared during the second month and reached a peak of 5000 conventional U during the third month of early carcinogenesis. Another AOA peak of above 7000 C.U. was observed in the sixth month of carcinogenesis, coinciding with the progressive growth of the tumor. After eight months of 4-DAB treatment, AOA decreased and its fluctuations were attributed to the varying rates of hepatoma cell multiplication. The biochemiluminescence kinetics curves obtained with liver homogenates prepared during various stages of hepatocarcinogenesis indicated that considerable free radical process alterations occurred in the early stages of the disease, when maximum luminescence was 34% lower than the related control peak. Two months after the beginning of DAB treatment, this peak was 46% lower than in the controls. Luminescence homogenates prepared from adenomatous tissue and from hepatocellular cancer tissue were 58% and 70% lower, resp., than that of control animal liver homogenates, indicating that liver homogenate biochemiluminescence decreases along with the carcinogenic process.

- 4441 INFORMATION THEORETICAL MODEL OF CARCINOGENESIS. (Ger.) Schaltegger, H. (Inst. Org. Chem. U. Bern, Switzerland). *Chimia* 26:303-307, 1972.

A universal biological information transformation model of carcinogenesis is presented. It is based on the assumption that external stimuli are transformed electrically by nerve receptors into RNA and proteins and, from these proteins, are again transformed electrically back to the external environment. Phenomenologically and thermodynamically, two kinds of information may be distinguished: reciprocal action between organism and environment, or kinetic information; and chemically stored information as "structural information", or potential information. Transfer of information from the environment via the receptors involves the central nervous system, peripheral nervous system and the intramural nervous system. The potential information is transferred

by the code molecules, DNA, RNA and proteins. These two groups of transformation are considered reversible under certain conditions, since the storage processes deal with cells that are not capable of division. The irreversible processes are associated with aging and with cancer, since the cells involved are able to divide, as for example in epithelial and parenchymal tissues.

4442 GLYCOLYTIC ENZYMES AND GLYCOLYSIS IN LUNGS AND PRIMARY LUNG CARCINOMAS IN MAN. (Ger.)

Sydow, G. (Inst. Cancer Res., Berlin, West Germany) and G. P. Wildner. *Acta Biol Med Germ* 27(3):651-654, 1971.

Studies of normal and primary cancerous lung tissue in humans are reported, including lactic acid formation and activities of hexokinase, phosphofructokinase, aldolase, and pyruvate kinase. The tissues were obtained immediately following surgery, normal tissue being taken from the same patient who had primary lung cancer. The results revealed an increased activity of glycolytic enzymes and lactic acid formation in the cancerous tissue compared to the normal tissue. Protein content is lower in the tumor tissue. Only about 20% of the 50 cancer cases show results close to normal tissue. The lactic acid content of the tumors is three times as high as the normal. Increased glycolytic metabolism may also be detected *in vivo*, in lung cancer, but large deviations in the individual normal lung tissues must be anticipated.

4443 ARYL HYDROCARBON (BENZOPYRENE) HYDROXYLASE IS STIMULATED IN HUMAN LYMPHOCYTES BY MITOGENS AND BENZ(a)ANTHRACENE. (E.) Whitlock, J. P., Jr. (Natl. Cancer Inst., Bethesda, Md.), H. L. Cooper and H. V. Gelboin. *Science* 177(4049):648-649, 1972.

The levels and inducibility of aryl hydrocarbon hydroxylase (AHH) were examined in resting and phytohemagglutinin (PHA)- or pokeweed mitogen (PWM)-stimulated human peripheral lymphocytes. Spectrofluorometric analysis showed that, although the endogenous AHH activity of unstimulated lymphocytes was low compared with that of rat liver microsomes or hamster embryo cells, stimulation with mitogens caused a two-fold increase in enzyme activity. Mitogen-treated cells preexposed to benz(a)anthracene showed a three- to eight-fold greater activity than unstimulated lymphocytes. Highest AHH activity was found in PWM-stimulated, benz(a)anthracene-treated cells. This finding is consistent with the previously reported observation that PWM stimulates endoplasmic reticulum proliferation in human lymphocytes more intensely than PHA. Therefore, AHH activity may be a useful biochemical marker for quantitative changes in the endoplasmic reticulum of differentiating lymphocytes.

4444 SPONTANEOUS REGRESSION OF CHEMICALLY INDUCED MALIGNANT LYMPHOMA IN SWISS MICE. (E.)

Rice, J. M. (Natl. Cancer Inst., Bethesda, Md.) and J. K. Davidson. *Cancer Res* 31:2008-2017, 1971.

Five-week-old female random-bred Swiss-Webster mice were given a single i.p. injection of 1-ethyl-1-nitrosourea (ENU, 1 μ ole/g). In two different experiments, 246 of 462 and 94 of 152 mice developed thymic or nonthymic malignant lymphoma between ten and 35 wk after treatment. A total of 38 of these cases underwent spontaneous regression accompanied by rapid wt loss and development of severe, usually fatal hypoplastic anemia. An additional 19 cases showed histological evidence of incipient regression at autopsy. Regression was characterized histologically by cellular depletion and fibrosis of lymphoid tissues and of visceral lymphoma deposits. Lymphomas that subsequently regressed could be transplanted by grafting lymph node cells into neonatal recipients during the rapidly proliferative phase of the disease. The anemia occurred only in those animals with regressing tumors and was not due to hemorrhage.

4445 TRANSFORMATION OF HAMSTER EMBRYO CELLS BY EPOXIDES AND OTHER DERIVATIVES OF POLYCYCLIC HYDROCARBONS. (E.) Huberman, E. (McArdle Lab., U. Wisconsin, Madison), T. Kuroki, H. Marquardt, J. K. Selkirk, C. Heidelberger, P. L. Grover and P. Sims.

Cancer Res 32(7):1391-1396, 1972.

Hamster embryo cells were exposed *in vitro* to: dibenz(a,h)anthracene (DBA) and its K-region derivatives; benz(a)anthracene (BA) and some of its derivatives; 3-methylcholanthrene (MCA), chrysene, phenanthrene and their K-region epoxides; 7-methylbenz(a)anthracene (MBA) and its K-region epoxide, 7-bromo-MBA, 7,12-dimethylbenz(a)anthracene (DMBA), and 7-bromo-DMBA. The K-region epoxide of DBA was more active in producing malignant transformation than DBA, the K-region phenol or the K-region *cis*- or *trans*-dihydrodiols. The K-region DBA phenol was the most cytotoxic DBA derivative, followed by the *cis*- and *trans*-dihydrodiols. The epoxide of BA was the most active transforming agent in the BA family of derivatives but the *cis*-dihydrodiol also transformed hamster cells. The *trans*-dihydrodiol of BA did not transform and was not cytotoxic. K-region epoxides of MCA, chrysene and phenanthrene were also more active transformers and more cytotoxic than the parent hydrocarbons. MBA was a more active transformer than its K-region epoxide when exposed to cells for seven days, but not when exposed to cells for four days. 7-Bromo-MBA and 7-bromo-DMBA were equally as active as their parent hydrocarbons in producing transformation.

4446 MYCOTOXINS AND THEIR ROLE IN THE ETIOLOGY OF NEOPLASIA IN MAN AND ANIMALS. (Pol.)

Aleksandrowicz, J. (Acad. Med., Cracow, Poland), B. Smyk, M. Czachor, M. Dulak and Z. Schiffer. *Pol Arch Med Wewn* 47(10):331-338, 1971.

comparison was made between the presence of fungi perfecti in the residences (and sometimes food) of 10 individuals with different forms of neoplasms and their presence in the homes of 170 healthy subjects. A statistically significant difference in frequency of occurrence of *Penicillium meleagrimum* and known oncogenic fungi (*Aspergillus flavus*, *Cladosporium herbarum*, *Rhizopus nigricans* and *Alternaria phylla*) was detected among the two groups. These fungi were present, resp., in 105, 83, 80, 54 and 31 of the 210 patients' residences as compared with 15, 29, 35 and 14 of the 170 control residences. Among leukemic subjects, *penicillium meleagrimum* and *Aspergillus flavus* were found with significant frequency in homes of patients with chronic lymphocytic leukemia or lymphosarcoma but not in homes of chronic granulocytic or acute leukemia patients. Investigation of nine residences of married couples in which husband and wife developed neoplastic disease within 2 yr of each other revealed a more frequent occurrence of the fungi (especially *A. flavus* : 8/9) among patients than among controls (2/9). A study of eight "cancer houses" (in which more than three persons developed cancer within 5 yr) also revealed frequent occurrence of *A. flavus* (7/8) and *P. meleagrimum* (6/8) when compared with controls (1/8 each). Further studies on the role of the penicillium, which is not carcinogenic but frequently accompanies fungi with oncogenic properties, are in progress.

4447 THE EFFECT OF ATMOSPHERIC FACTORS ON THE OCCURRENCE OF SKIN CANCERS. (Pol.) Szyroki, (Dermatol. Clin. PAM, Szczecin, Poland) and Z. Salewicz. *Przegl Dermatol* 58(5):569-573, 1971.

Analysis of records of 729 skin cancer patients (467 men, 267 women) treated between 1951-1969 revealed that average age was 59.2 yr for both sexes combined, 55 yr for women and 56.9 yr for men. Morbidity was greatest (53.5% of all patients) between the ages of 50-60; 28.1% of the patients were under 50 and 0.5% were under 30 years of age. Place of residence (village or town) seemed to have no effect on skin cancer incidence, but occupational exposure did: 16.6% exposed as opposed to 23.2% occupationally non-exposed and 18.2% occupational undefined. Lesions were localized on exposed parts of the body in 97.6% of the patients and on covered parts in only 2.4%. Lesions were found most frequently on the lower lip (19.2%), especially among men (255 of 467 as opposed to 16 of 262 women); cheek (19.2%), especially among men (79 of 262 as compared to 61 of 467 men); nose (5.7%) and forehead (5.9%). Histologic classification of lesions revealed that epithelioma basocellulare occurred more frequently among women (55.4%), carcinoma spinocellulare more frequently among men (87.3%).

4448 INTERACTION OF CARCINOGENIC METALS WITH TISSUE AND BODY FLUIDS. (E.) Weinzierl, (Strangeways Lab., Cambridge, England) and M. Webb. *J Cancer* 26(4):279-291, 1972.

Allic cobalt, nickel, cadmium, zinc and copper were

mixed with sterile horse serum and the dissolution of the metals in serum was observed. The carcinogenic metals, nickel and cadmium, dissolved slowly in serum; their rates of dissolution were the same in the presence or absence of oxygen. In contrast, cobalt and copper dissolved more quickly in the presence of oxygen. In all "metal sera," the cations were bound, although in different proportions, by proteins as well as by small diffusible molecules. Radioactive nickel implanted in rat muscle *in vivo* dissolved rapidly; 80% of dissolved nickel was distributed among small diffusible components of muscle tissue. Cobalt also dissolved readily in rat muscle, its solubility in this system exceeding that in horse serum. Copper, cadmium and zinc also dissolved in muscle *in vivo* and bound to small diffusible molecules, rather than to protein components. Metallic ions were not bound by specific cation carriers, either *in vivo* or *in vitro*, but were distributed among a number of components. Solubility was not specific for carcinogenic metals, either in serum or in muscle.

- 4489 COCARCINOGENIC ACTION OF MECHANICAL DAMAGE AND X-RAY IRRADIATION ON INTRAMANDIBULAR TISSUE OF MICE. (E.) Eulderink, F. (J. A. Cohen Inst. Radiation Path. Radiation Protection, Leiden, The Netherlands) and Th. G. van Rijssel. *J Nat Cancer Inst* 49:821-827, 1972.

The effect of combined X-ray irradiation and continuous mechanical irritation was studied. Chronic mechanical irritation of enamel-forming epithelium by implantation of nylon threads or steel wires in alveolar sockets of (♀ WLLf X ♂ O₂₀)F₁ mice, which induces intramandibular carcinoma, was combined with X-ray irradiation of the head in a single dose of 500 or 1000 rads. These doses did not induce tumors when applied without other treatment. Implantation and irradiation together caused a marked increase of the number of induced tumors as compared with implantation alone. Both carcinomas and benign mesenchymal tumors (osteofibromas) developed. At a dose level of 500 rads, this increase was significant for carcinomas and for all types of tumor; at a dose of 1000 rads this was true for all tumors but not for carcinomas alone. Combined with thread implantation, irradiation gave more tumors in a dose of 500 rads than in one of 1000 rads; for carcinomas this was statistically significant. At higher dose levels the cell-damaging action of the X rays probably interferes with the carcinogenic influence.

- 4490 LEUKAEMIA, MALIGNANCIES AND OTHER LATE EFFECTS FOLLOWING ADMINISTRATION OF THOROTRAST. (E.) Da Silva Horta, J. (Fac. Med., U. Lisbon, Portugal), J. D. Abbott, L. Cayolla da Motta and M. Helena Tavares. *Z Krebsforsch* 77(3):202-216, 1972.

Cancer incidence in 1178 Portuguese patients exposed to Thorotrast (a stabilized solution of thorium dioxide) for diagnostic purposes between 1930-1955 was investigated. A control population matched for age and sex but injected with a nonradioactive agent served for comparison. The study showed a gross excess of liver hemangioendotheliomas (16 histologically confirmed cases) in Thorotrast-treated subjects. Cholangiocarcinomas and hepatomas of the liver were also frequently present in the Thorotrast population. There were three primary bone tumors and five cases of lung cancer. The latter could not be unequivocally attributed to Thorotrast, since the smoking habits of the Thorotrast-exposed subjects were unknown. Twenty-two fatal blood dyscrasias, especially myeloid leukemias, occurred in the Thorotrast group. These blood dyscrasias appeared about 20 yr after irradiation in contrast to the five to seven year latent period of dyscrasias induced by external irradiation.

- 4491 THE EFFECT OF AGE AT EXPOSURE TO A SUB-LETHAL DOSE OF FAST NEUTRONS ON TUMORIGENESIS IN THE MALE RAT. (E.) Castanera, T. J. (Naval Radiol. Defense Lab., San Francisco, Calif.), D. C. Jones, D. J. Kimeldorf and V. J. Rosen. *Cancer Res* 31:1543-1549, 1971.

Male Sprague-Dawley rats aged one month ("juveniles") or 21 months ("old") were given a single whole body dose of 215 rads of fast neutron irradiation; 3-month-old rats ("young adults") were given 230 rads. Rats were observed for life and the incidence of primary epithelial and nonepithelial, benign and malignant tumors was tabulated. Irradiated juveniles showed significant excesses over nonirradiated controls in all tumor categories except malignant epithelial tumors. Irradiated young adults showed excess tumor incidence only in the malignant epithelial and malignant nonepithelial categories. Irradiated old rats did not show significant excesses in any tumor category. Irradiated juveniles differed from irradiated young adults in having excesses of benign nonepithelial tumors. Also, while irradiated juveniles had significant excesses of multiple malignant epithelial tumors, the excesses of tumor incidence in this category were much greater for young adults. The skin, kidneys and Langerhan's islands in the two younger groups showed marked susceptibility to radiation. Juvenile breast tissue, bone, thyroid, peripheral nerves and skeletal muscles were especially susceptible, as were young adult lungs.

- 4492 THE EFFECT OF AGE, FRACTIONATION, AND DOSE ON RADIATION CARCINOGENESIS IN VARIOUS TISSUE OF MICE. (E.) Vesselinovitch, S. D. (Pritzker Sch. Med., U. Chicago, Ill.), E. L. Simmons, N. Mihailovich, K. V. N. Rao and L. S. Lombard. *Cancer Res* 31:2133-2142, 1972.

Mice of the C57BL/6 x C3H F₁ strain were given X-irradiation beginning on the first, 15th or 42nd day of life. X-irradiation to a total dose of 320 R was delivered in either a single dose, or in two doses four days apart, or in four doses four or seven days apart. Some mice were given 480 R of irradiation as four exposures seven days apart. Tumor incidence at 86 wk was observed. Among tumors developed, usually late in life, by irradiated mice were malignant melanomas, hepatomas, lung adenomas, Harderian gland cystadenomas and ovarian tumors. Irradiation increased tumor incidence. The incidence of malignant lymphoma did not vary among mice irradiated at different ages, but irradiation increased lymphoma incidence from less than 1% in unirradiated mice to 11.36%. The 480 R dose was more lymphomagenic than the smaller doses. Age at irradiation did not affect hepatoma incidence, but irradiation increased hepatoma incidence in males. The four dose, 320 R total at four-day intervals was the most effective schedule for causing hepatoma. Irradiation increased lung adenoma incidence, but no irradiation schedule was more tumorigenic than the others. Infant and adult mice were more likely to develop Harderian gland tumors after irradiation than were newborns. Age also influenced ovarian tumor incidence; one-day-old mice were less responsive to irradiation than were infants or adults. The types of tumors developed by 86 wk old irradiated mice were also seen in unirradiated mice allowed to live for 166 days.

4493. ASPECTS OF THE BIOLOGY AND RADIATION RESPONSE OF CLONED C3H MOUSE MAMMARY CARCINOMA CELLS *IN VITRO* AND *IN VIVO*. (E.) Cohn, N. K. (U. Wisconsin Med. Sch., Madison), and K. H. Clifton. *Europ J Cancer* 7(6):505-514, 1971.

Twenty cell lines were established from nine primary or transplanted mammary carcinomas from C3H/Wr mice. In general, cell lines from tumors that had been transplanted and grew well *in vivo* were more readily established than those from primary tumors or tumors which were difficult to transplant. Both epithelioid and spindle cell types were observed in outgrowths from all tumors. With the exception of two spindle cell lines, all lines gave rise to tumors after inoculation in histocompatible mice. Studies with two representative cloned epithelioid and one cloned spindle cell line showed that tumors grew more rapidly from cultured cells which had been recently passed in mice than from long-term cultured cells. Experiments designed to determine if this mouse-passage effect resulted from pronounced antigen differences between long-term cultured cells and the most mice were negative. Data from an experiment in which $^{125}\text{IUdR}$ -labelled cells were employed indicated that a greater percentage of the inoculated mouse-passaged cells survived to contribute to tumor formation compared with long-term cultured cells. When lethally irradiated cells were included in the inocula, the effective number of *in vitro* colony-forming units required for tumor formation *in vivo* was found to be about 2 and 3 for the epithelioid cell lines, resp. The three cell lines studied had differing radiosensitivity (D_0) values when irradiated *in vitro*. The D_0 for irradiation *in vivo* of one passaged epithelioid cell line was similar to the D_0 of the transplanted tumor strain from which it was derived.

4494. COMPARATIVE STUDIES ON INDUCTION AND REJOINING OF DNA SINGLE-STRAND BREAKS BY RADIATION AND CHEMICAL CARCINOGEN IN MAMMALIAN CELLS *IN VITRO*. (E.) Horikawa, M. (Dept. Radiat. Biol., Kanazawa U., Japan), M. Fukuhara, F. Suzuki, O. Nikaide and T. Sugahara. *Exp Cell Res* 70(2):349-359, 1972.

Mouse fibroblastic L cells, pig kidney cells and Ehrlich ascites tumor cells were exposed to X-irradiation (1-10 KR) or to 4-hydroxyaminoquinoline 1-oxide (4-HAQO). To investigate single stranded DNA breaks induced by irradiation of 4-HAQO, the treated cells were subjected to sedimentation analysis on 5-20% alkaline sucrose gradients. The repair rejoining of DNA breaks was observed during incubation of treated cells. Single-stranded DNA breaks were induced almost as a linear function of X-ray dose. 4-HAQO in concentrations higher than 1×10^{-5} M induced breaks, while 5×10^{-6} M doses did not induce breaks. Breaks induced by X-irradiation were rejoined by 15-60 min of cell incubation after irradiation; breaks induced by 4-HAQO were rejoined by three and 24 hr after treatment. Rejoining of DNA breaks consisted of a rapid rejoining process continuing for a short

time after the start of cell incubation after treatment and a subsequent slower process of longer duration. When X-irradiated or 4-HAQO-treated cells were treated with puromycin, rejoining of single-strand DNA breaks was completely suppressed, despite the fact that puromycin did not inhibit normal cell DNA synthesis. Pretreatment of cells 72 hr before irradiation or 4-HAQO, and posttreatment 24 hr after irradiation or 4-HAQO, with hydroxyurea did not suppress rejoining of DNA breaks, even though hydroxyurea was extremely inhibitory of normal DNA synthesis.

- 4502 NATURE OF VIRUS-PRODUCING ROUS SARCOMA CELLS IN HAMSTERS TREATED WITH ANTILYMPHOCYTE SERUM: IMMUNOCHEMICAL, CYTOGENETICAL, AND ELECTRON MICROSCOPIC OBSERVATIONS. (E.) Halleux, F. de (U. Louvain, Belgium), H. Van Den Berghe and A. Declève. *J Nat Cancer Inst* 48(6):1607-1618, 1972.

Two day old hamsters were inoculated s.c. with chicken tumor cells induced by the Bryan high-titer strain of Rous sarcoma virus (BH-RSV); tumors appeared only in inoculated hamsters treated with heterologous antilymphocyte serum. When the BH-RSV-induced tumors were tested in immunodiffusion tests against antihamster tissue immune serum, they showed reactions of identity; reactions of partial identity were seen when tumors were reacted against anti-chicken immune serum. Characteristic fluorescent patterns were seen with both antisera in immunofluorescence tests with the tumors. In these tests, antihamster serum stained connective tissue cells in the tumors, while antichicken serum stained tumorous cells. Mitotic figures in tumor cells showed the chromosome complement of both chick and hamster cells, hamster cell complements being more common. Under the electron microscope tumor cells were similar to chicken sarcoma cells. C-type virus particles were seen in all tumors; the number of particles increased from six hr to eight days after inoculation of Rous sarcoma cells.

- 4503 HEMATOPOIETIC CFU IN MICE INFECTED BY THE POLYCYTHEMIA-INDUCING FRIEND VIRUS. I. NUMBER OF CFU, AND DIFFERENTIATED PATTERN IN THE SPLEEN COLONIES. (E.) Wendling, F. (I.N.S.E.R.M., Orsay, France), P. E. Tambourin and P. Jullien. *Int J Cancer* 9(3):554-566, 1972.

C3H-He mice were inoculated i.v. with polycythemia-inducing Friend virus (FVP) preparations obtained from spleens of virus-infected mice. In some cases, mice were given 950 R whole-body X-irradiation. The number of colony-forming U (CFU) in spleen, femoral bone marrow and blood of infected mice was observed using an exogenous spleen colony assay. The total number of CFU in spleens of mice infected with FVP was 37,000-120,000 by 30 days after inoculation of virus; the numbers of CFU in spleens of uninfected mice was $4,720 \pm 460$. The number of CFU in bone marrow of infected mice was not different from that in uninfected mice. The number of CFU in blood of FVP-infected mice was 40,000, compared to 45 CFU in blood of uninfected mice. The fraction of CFU which settled in spleens of irradiated mice injected with spleen or marrow cells from normal or FVP-infected mice was determined. The proportion of CFU recovered from spleens of irradiated mice was similar in mice given normal or FVP-infected marrow cells; the proportion of CFU in spleens of irradiated mice given spleen cells from FVP-infected mice was decreased relative to that in spleens of irradiated recipients of normal spleen cells. The cytological characteristics of colonies developing in spleens of irradiated mice grafted with hematopoietic cells of normal or FVP-infected donors was investigated. No important differences were seen

between differentiation patterns of erythrocytic, granulocytic, megakaryocytic or mixed colonies produced by mice given normal or FVP-infected hematopoietic cells.

- 4504 INHIBITORY EFFECT OF CARCINOGENIC AROMATIC HYDROCARBONS ON TRANSFORMATION OF 3T3 CELLS BY SV40. (E.) Docherty, J. J. (Dept. Microbiol., U. Arizona, Tucson), P. P. Ludovici and G. T. Schloss. *Proc Soc Exp Biol Med* 140(3):969-973, 1972.

7,12-Dimethylbenz(a)anthracene (DMBA) or 3-methylcholanthrene (3-MC) were added to suspensions of 3T3 cells in concentrations of 0.0005-0.5 $\mu\text{g/ml}$ and the effect on 3T3 cell plating efficiency was observed. Doses of 0.0005 $\mu\text{g/ml}$ DMBA and 0.005 $\mu\text{g/ml}$ 3-MC had no toxic effect on cell plating efficiency. Accordingly, DMBA or 3-MC were added in these amounts to 3T3 cells 48 hr before cells were infected with SV40 (A group), at the time of SV40 infection (B group), or 24 hr after virus infection (C group). In groups A and B, where DMBA or 3-MC was in contact with cells for 48 hr or 3 hr, resp., the number of SV40-transformed 3T3 clones was not reduced. In group C, however, where carcinogens were in contact with cells for seven days, the transformation of 3T3 cells by SV40 was decreased. The percentage of transformed clones in DMBA- or 3-MC-treated SV40-infected cultures in groups A and B ranged from 3.2-1.8%. The percentage of transformed clones in infected group C cultures treated with carcinogens ranged from 1.0-2.0%. The carcinogens had no direct effect on SV40 infectivity when SV40 was incubated with 0.002-200.0 $\mu\text{g/ml}$ of carcinogens before being titrated on African green monkey cells.

- 4505 VIRUS PARTICLES IN RAT LEUKEMIAS INDUCED BY N-NITROSOBUTYLUREA. (E.) Kodama, T. (Hokkaido U. Sch. Med., Japan), M. Hosokawa, E. Gotohda, F. Sendo and H. Kobayashi. *Gann* 63(2):261-263, 1972.

C-type virus particles were identified by electron microscopy in leukemic tissues induced in Wistar-King-Aptekman/Mk rats by oral administration of N-nitrosobutylurea for four months. The virus particles were present in both primary and transplantable leukemia tissues and in cell cultures obtained from transplantable leukemia. Mature and immature C-type particles were observed in intercellular spaces; budding of virus particles was seen at the membrane surface of the leukemia cells. In general, the virus content of the specimens was low (one virus particle per 200-500 cells). Particle frequency was slightly increased in primary leukemia compared with transplantable leukemia, but no difference in frequency was seen in the stem cell and erythroblastic types of leukemia. No virus particles were observed in organs of normal controls or in control N-nitrosobutylurea-induced primary and transplantable mammary tumors.

06 LIGHT AND ELECTRON MICROSCOPIC STUDIES OF
TUMORS INDUCED BY SMALL PLAQUE VARIANT
CHICKEN EMBRYO LETHAL ORPHAN VIRUS. (E.)

sty, V. (Animal Path. Dept., U. Rhode Island,
ngston), V. J. Yates, J. Anderson, R. E. Wolke,
Pendola, and P. W. Chang. *Cancer Res* 32(10):
04-2113, 1972.

The light and electron microscopic appearances of
our solid tumors induced in hamsters by the
small-plaque variant of chicken embryo lethal
orphan virus were studied. The tumors were
composed of cells ranging from those that were
differentiated to those with fibroblastic
differentiation. Ultrastructurally, the neoplastic
cells were characterized by nuclei with irregular
contours; well-developed, rough endoplasmic
reticulum; mitochondria; and abundant, free
ribosomal clusters. One outstanding feature of
these cells was the wrapping of the cisternal
profiles of rough endoplasmic reticulum around the
mitochondria. Although no adenovirus particles
were discernible, virus-like particles resembling
either the intracytoplasmic hamster type A
particles or the Bernhard type were detected
in two of the four tumors examined. The sera from
two of the four tumor-bearing hamsters contained
small-plaque virus specific "T" antibodies, as
demonstrated by indirect immunofluorescent
techniques.

07 CIRCULATION OF LYMPHOID CELLS IN MICE IN-
FECTED WITH FRIEND LEUKEMIA VIRUS. (E.)

Winbridge, D. R. (London Hosp. Med. Coll., England)
and M. Bendinelli. *J Nat Cancer Inst* 49(3):773-781,
1972.

Friend virus (FV) depressed the immune response of
C57BL/c mice to sheep red cells (SRC) but not to
logeneic lymphoid cells. This difference was
at least partly due to the fact that the major re-
sponse to SRC occurred in the spleen, for FV infec-
tion had little effect when SRC were given by foot-
pad injection. In an attempt to explain the function
of the spleen, the circulation of lymphoid cells was
studied in normal and infected mice. As judged by
Cr-labeling, the lymphoid organs of infected mice
accepted cells more or less normally and the
ability of lymphoid cells from infected mice to
migrate to lymphoid tissue was probably unaltered, if
one allows for the dilution of lymphocytes by neo-
plastic cells in the spleen. ⁷⁵Se-labeling ex-
periments showed that the transit of circulating
lymphoid cells was greatly slowed in the infected
spleen. This might affect their ability to interact
with resident cells in those immune responses
dependent on lymphocyte cooperation.

08 THE EFFECT OF DIBUTYRYL CYCLIC ADENOSINE
MONOPHOSPHATE ON SYNTHESIS OF SULFATED
ACID MUCOPOLYSACCHARIDES BY TRANSFORMED FIBROBLASTS.

(E.) Goggins, J. F. (Natl. Inst. Dental Res.,
Bethesda, Md.), G. S. Johnson and I. Pastan.

J Biol Chem 247(18):5759-5764, 1972.

The effect of dibutyryl-cyclic adenosine 3',5'-
monophosphate and theophylline on the incorporation
of [³⁵S]sulfate into acid mucopolysaccharides by
3T3 and SV3T3 fibroblasts was studied. SV40 trans-
formation of 3T3 fibroblasts produced a marked
decrease in the rate of synthesis of acid mucopoly-
saccharides, in agreement with the data of others.
When the transformed cells were grown in medium
supplemented with dibutyryl-cyclic AMP and theo-
phylline for three days, they secreted, on the
basis of cell protein, approximately 250% more
labeled acid mucopolysaccharides during a 24-hour
labeling period than did the nontreated controls.
The secretion of a variety of sulfated acid muco-
polysaccharides was increased including chondroitin-
4- and -6-sulfate and dermatan sulfate. Comparison
of the rate of sulfate incorporation into acid
mucopolysaccharides and the rate of loss of
previously labeled acid mucopolysaccharides from
the cells indicated that the effect was due to a
greater rate of synthesis of these compounds at
the time of labeling rather than due to a decrease
in the rate of their degradation.

4509 STUDIES WITH HUMAN PAPILLOMA VIRUS MODELED
AFTER KNOWN PAPOVAVIRUS SYSTEMS. (E.)

Butel, J. S. (Baylor Coll. Med., Houston, Texas).
J Nat Cancer Inst 48(2):285-299, 1972.

Papilloma virus-bearing human wart tissue was
cultured and tested in complement fixation tests
with rabbit anti-papilloma virus serum. An aver-
age of 2.3×10^7 papilloma virus particles/complement
fixing U (equivalent to about 10^9 particles/ml)
were needed to fix complement in wart tissue
cultures. No virus hemagglutinin was detected.
Several species of host cell, including human
embryonic kidney (HEK), green monkey kidney, KB,
HeLa and human skin cells, were surveyed for sus-
ceptibility to papilloma virus replication and
transformation. These host cells failed to support
virus replication. Papilloma virus DNA in the
presence of DEAE dextran also failed to produce
morphological changes, cytopathic effect or viral
antigen in HEK cells. However, uptake of radio-
active precursor into DNA synthesized in cultures
of HEK cells was increased in the presence of
papilloma virus particles. Representatives of
major virus groups were tested for helper virus
activity with papilloma virus. No helper or
interfering interactions between papilloma virus
and the others were seen. Papilloma virus inocula-
tion produced no papillomas in sacrificed weanling
hamsters, and no virus-induced antigens were
detected in rejection tests with hamster cells
inoculated with papilloma virus and transplanted
into hamsters.

4510 PROPERTIES OF SOMATIC CELL HYBRIDS BETWEEN
MOUSE CELLS AND SIMIAN VIRUS 40-TRANS-
FORMED RAT CELLS. (E.) Noordaa, J. van der

(Hlth. Res. Lab., U. Amsterdam, Netherlands), A. van Haagen, J. M. M. Walboomers and H. van Someren. *J Virol* 10(1):67-72, 1972.

Primary rat cells were transformed with SV40 and fused by Sendai virus mediation with a strain of thymidine kinase-deficient 3T3 mouse cells (3T3TK⁻). Lactate dehydrogenase, 6-phosphogluconate dehydrogenase and indophenol oxidase patterns in four hybrid cell lines were observed, confirming the hybrid nature of these lines. The parental 3T3TK⁻ cells had a modal chromosome number of 63 and the rat cells a modal number of 42; hybrid cell lines at subculture 12 had modal chromosome numbers of 70-80, all telocentric or acrocentric. Over a year, only 10-20% of chromosomes were lost by hybrids. Neither SV40-transformed parent cells nor hybrid cell lines shed infectious SV40. Hybrids at subculture 15 contained SV40 T antigen. In agglutination, growth in soft agar and serum requirements, hybrid cells resembled the transformed parent line.

4511 CELL CYCLE-DEPENDENT ACTIVATION OF ROUS SARCOMA VIRUS-INFECTED STATIONARY CHICKEN CELLS: AVIAN LEUKOSIS VIRUS GROUP-SPECIFIC ANTIGENS AND RIBONUCLEIC ACID. (E.) Humphries, E. H. (McArdle Lab., U. Wisconsin, Madison) and H. M. Temin. *J Virol* 10(1):82-87, 1972.

Primary chick embryo fibroblasts were infected with Schmidt-Ruppin Rous sarcoma virus (SRV); attempts were made to detect avian leukosis virus group-specific (gs) antigen in both stationary and dividing SRV-infected cells. Indirect immunofluorescence, complement fixation and immunoabsorption fluorescence were used to test for avian leukosis gs antigens. Stationary SRV-infected cells showed no strong reactions for this gs antigen, even at 130 hr postinfection, while more than 80% of actively dividing cells possessed the antigen. It was known that stationary SRV-infected cells did not release infectious virus. In related experiments, attempts were made to bring about RNA-DNA hybridization between RNA from stationary SRV-infected cells and DNA from the B77 virus endogenous RNA-directed DNA polymerase. RNA from stationary infected cells hybridized only slightly with the B77 DNA. RNA from RSV-infected dividing cells contained 20- to 150-fold more avian leukosis virus-specific RNA than stationary infected cultures.

4512 ALTERATION OF SKIN IN GROSS LEUKEMIA. IV. TEST OF ALLOGRAFT HYPOTHESIS. (E.)

Mariani, T. (Pediatrics, Path. Radiation Res. Labs., U. Minnesota, Minneapolis), Y. Maruyama and R. A. Good. *J Nat Cancer Inst* 49(3):879-885, 1972.

To test the hypothesis that an immunologic response underlies the rejection of skin from syngeneic tumor-bearing animals, (C3H/Bi X DBA/2)F₁ recipients were given 400R total-body X irradiation, neonatally thymectomized, or both irradiated and

thymectomized. These animals were grafted with syngeneic skin from mice bearing Gross passage A tumors for 4, 7, or 11 days. The rates of graft rejection, tumor development at the graft site, and survival time for these immunosuppressed animals did not differ from those of immunologically intact recipients. By contrast, allogeneic skin was not rejected by animals treated with the same immunosuppressive manipulations. These experiments indicate that syngeneic skin-graft rejection, the "heterogenization phenomenon," is not of immunologic origin.

4513 AN ANEMIA-INDUCING VIRUS DERIVED FROM TUMORS CAUSED BY MURINE SARCOMA VIRUS-MOLONEY. (E.) Taylor, D. O. N. (California State Dept. Public Hlth., Berkeley), N. E. Cremer, L. S. Oshiro and E. H. Lennette. *J Nat Cancer Inst* 49(3):829-845, 1972.

Cells from rat tumors induced by Moloney sarcoma virus were explanted and cultured *in vitro*. When cell-free fluids from the fifteenth *in vitro* passage were injected into newborn Osborne-Mendel (O/M) rats, severe anemia developed. Subsequent rat-plasma passages also induced anemia in O/M rats, but sarcomas were no longer observed. The agent causing the anemia was filterable and ether labile. It was contained in material banding at a density of 1.14-1.18 in which large numbers of C-type virus particles were observed. The agent was neutralized by Moloney leukemia virus antiserum, indicating it was closely related to the murine leukemia viruses. Sequential hematologic studies and necropsies demonstrated that while this agent produced erythroblastic splenomegaly and anemia, as observed with the Harvey strain of murine sarcoma virus, Kirsten murine erythroblastosis virus, and Friend and Rauscher leukemia viruses, distinct differences occurred in regard to development of sarcomas, osteolytic lesions, cystic lesions, and host susceptibility. Thus, it appears that an anemia-inducing virus, distinct from other strains of virus in the murine leukemia-sarcoma complex, has been found as a result of *in vitro* cultivation.

4514 INCREASED SUSCEPTIBILITY OF CELLS FROM CANCER PATIENTS WITH XY-GONADAL DYSGENESIS TO SIMIAN PAPOVAVIRUS 40 TRANSFORMATION. (E.) Mukerjee, D. (U. Texas Med. Branch, Galveston), J. M. Bowen, J. M. Trujillo and A. Cork. *Cancer Res* 32:1518-1520, 1972.

Skin fibroblast cultures from two cancer patients with XY-gonadal dysgenesis were infected with SV40. Infected cells were subcultured for two to three weeks, and the numbers of transformed colonies were observed. The two XY-gonadal dysgenesis patients had mean transformation frequencies of $70.4 \pm 1.9/10^4$ cells and $73.5 \pm 0.7/10^4$ cells resp., while chromosomally normal subjects had mean transformation frequencies of $2.1-4.2/10^4$ cells. Thus, XY-

gonadal dysgenesis resembles disorders such as Fanconi's aplastic anemia and Klinefelter's syndrome, which are also associated with increased susceptibility to SV40 transformation *in vitro*.

4515 IMMUNOLOGIC EVIDENCE SUGGESTING A VIRAL ETIOLOGY OF HUMAN OSTEOSARCOMA. (E.) Reilly, C. A., Jr. (Argonne Natl. Lab., Ill.), D. J. Pritchard, B. O. Biskis and M. P. Finkel. *Cancer* 30(3):603-609, 1972.

Sera from osteosarcoma patients were used in an indirect immunofluorescence assay to detect sarcoma-specific antigen(s) in human osteosarcomas. Fifty-seven of 58 of these sera and two of 24 normal sera reacted with osteosarcoma tissue as demonstrated by the fluorescence of both cell membrane and cytoplasm. Human osteosarcoma sera also detected sarcoma-specific antigen(s) in six of seven sarcomas induced in hamsters inoculated at birth with cell-free extracts of human osteosarcomas. Hamster carcinomas, reticular tissue tumors, and normal tissues failed to react with human osteosarcoma sera. The presence of human sarcoma-specific antigen(s) in the sarcomas of six hamsters treated with human osteosarcoma extracts suggests that these tumors were induced by a human osteosarcoma virus.

4516 STRUCTURE AND FUNCTION OF THE POLYPEPTIDES IN SIMIAN VIRUS 40. II. TRANSCRIPTION OF SUBVIRAL DEOXYNUCLEOPROTEIN COMPLEXES *IN VITRO*. (E.) Huang, E.-S. (Dept. Bacteriol. U. North Carolina, Chapel Hill), M. Nonoyama and J. S. Pagano. *J Virol* 9(6):930-937, 1972.

Purified SV40 virions were dissociated in alkaline buffers at pH 10.5 into a soluble protein and a deoxynucleoprotein complex (DNP-I) containing the viral DNA and the four minor of the six structural viral polypeptides. DNP-I was in turn dissociated into soluble protein and DNP-II by equilibrium centrifugation in CsCl. DNP-II contained mainly the viral DNA and a small remnant of viral protein, apparently viral polypeptide no. 3, which was tightly bound to viral DNA. The DNA transcription *in vitro* of DNP-I and -II with *E. coli* DNA-dependent RNA polymerase was studied. The rate of transcription with DNP-I as template was 30% of the rate with SV40 DNA component I (supercoiled) as template; the transcription rate with DNP-II as template was 80% of the SV40 component I rate. In dimethyl sulfoxide gradients, the complementary RNA (cRNA) synthesized from DNP-I was one-third to one-half the size of the cRNA species from SV40 DNA component I and DNP-II. Competition experiments between the cRNA species of DNA component I, DNP-I and DNP-II showed that with DNP-I as template only half the SV40 genome sequences were transcribed with *E. coli* transcriptase, while with DNP-II as template, most of the DNA was transcribed. Template activity of DNP-I and -II with a highly active form II RNA polymerase from SV40-infected permissive monkey

kidney cells followed a similar pattern. The results indicate that structural nucleoproteins of SV40 bind nonrandomly to viral DNA and effect the transcription of some subset of its sequences *in vitro*.

4517 FURTHER STUDIES OF A SIMIAN VIRUS 40-LIKE VIRUS ISOLATED FROM HUMAN BRAIN. (E.) Weiner, L. P. (Johns Hopkins Sch. Med., Baltimore, Md.), R. M. Herndon, O. Narayan and R. T. Johnson. *J Virol* 10(1):147-149, 1972.

A viral agent isolated from the brain of a patient with progressive multifocal leukoencephalopathy was reisolated by growing on fetal human brain cells (HFB). Cytopathic effects (CPE), consisting of pyknosis and cell lysis, were seen in HFB inoculated with the virus. Indirect fluorescent antibody staining with monkey anti-SV40 serum demonstrated nuclear fluorescence. Under the electron microscope, infected HFB cells showed papovavirus-like particles morphologically indistinguishable from SV40-polyoma group viruses. The virus reisolated in HFB cells produced CPE in primary African green monkey kidney cells and BSC-1 cells. In these cells, as in HFB, the virus showed antigenic similarities to SV40.

4518 RESCUE OF ROUS SARCOMA VIRUS FROM ROUS SARCOMA VIRUS-TRANSFORMED MAMMALIAN CELLS. (E.) Coffin, J. M. (McArdle Lab., U. Wisconsin, Madison). *J Virol* 10(1):153-156, 1972.

R(B77) cells, from a line of rat embryo fibroblasts transformed by B77 avian sarcoma virus, were exposed to gamma radiation and added to chicken embryo fibroblasts treated with UV-inactivated Sendai virus. Rescue of Rous sarcoma virus (RSV) from fused R(B77) and chicken cells was monitored by observing focus formation. R(B77) yielded 10^{-2} to 10^{-3} foci/cell, while the D6 clone of R(B77) was twice as efficient at focus production as uncloned R(B77) cells. When chicken cells in the fusion procedure were pretreated with mitomycin C or gamma radiation to suppress cell division, the ability of B77 virus-infected chicken cells to act as infectious centers was greatly impaired, although rescue of RSV from these treated chicken cells was not affected. Fusion of R(B77) cells with chicken red blood also led to virus rescue, although with less efficiency than with embryo fibroblasts. Therefore, virus rescue from R(B77) cells was mediated by a factor contributed by the chicken cells.

4519 RELATIONSHIP AMONG TUMORIGENICITY, T ANTIGEN, AND VIRUS-SPECIFIC TRANSPLANTATION ANTIGEN IN ADENOVIRUS TYPE 12 TRANSFORMED AND TUMOR CELLS. (E.) Akagi, T. (Okayama U. Med. Sch., Japan) and K. Ogawa. *Gann* 63(3):307-312, 1972.

Three lines of adenovirus type 12-transformed hamster cells (Tr-P-3(a), Tr-P-4 and Tr-WE-1) and one line of cells from an adenovirus-induced hamster tumor (Ham T-4) were tested for tumorigenicity in hamsters and for T antigen and virus-specific transplantation antigen (VSTA), resp., in immuno-fluorescence tests and tumor-development inhibition tests. Tr-P-4 cells, which had both T and VSTA antigens, were the most tumorigenic of the four lines tested. Tr-We-1 cells lacked T and VSTA antigens but were highly tumorigenic. The other two lines had T antigen, showed slight VSTA antigenicity, and were tumorigenic.

- 4520 INHIBITION OF SYNTHESIS OF HERPES SIMPLEX VIRUS DEOXYRIBONUCLEIC ACID BY A CARCINOGENIC POLYCYCLIC AROMATIC HYDROCARBON. (E.) Goldberg, R. J. (Hershey Med. Ctr., Pennsylvania State U., Hershey), J. J. Docherty and F. Rapp. *Proc Soc Exp Biol Med* 140(3):1054-1058, 1972.

Rabbit kidney cells were infected with herpes simplex virus (HSV) type 2; an hour later, infected cultures were treated with 7,12-dimethylbenz(a)anthracene (DMBA) or anthracene. Treated infected cultures were pulsed with ^3H -thymidine and autoradiography was used to monitor ^3H -thymidine uptake by nuclear DNA, as a measure of DNA synthesis in infected DMBA-treated cells. Uptake of label in infected cells given no other treatment greatly exceeded that in uninfected cells; in infected and uninfected cultures, 58% and 3% of cells, resp., were labeled. Antihormones did not affect label uptake by HSV-infected cells, but DMBA treatment produced a marked reduction of ^3H -thymidine uptake by infected cells (28% of cells labeled when exposed to 20 $\mu\text{g}/\text{ml}$ DMBA). Test compounds were not cytotoxic for HSV-infected cells.

- 4521 ACTIVATING AND PROTECTIVE CAPACITIES OF A PURIFIED ELECTROPHORETIC FRACTION OF MURINE LEUKEMIA VIRUS FOR MURINE LEUKEMIA VIRUS INFECTIVITY. (E.) Fischinger, P. J. (Nat'l. Cancer Inst., Bethesda, Md.), J. Lange and W. Schäfer. *Proc Nat Acad Sci USA* 69(7):1900-1904, 1972.

Cultured Friend leukemia virus (FLV) was treated with sodium dodecyl sulfate and phenol; viral proteins were precipitated from the phenol phase and protein separation was performed by preparative polyacrylamide slab gel electrophoresis. The purified FLV fraction was mixed with various murine leukemia viruses (MuLV) and inoculated on mouse cells; in some cases viruses exposed to FLV fractions were later treated with MuLV-specific neutralizing antisera. Treatment with FLV fractions significantly enhanced infectivity of MuLV inocula, as measured by focus induction. FLV fractions lost this enhancing capacity after chloroform-methanol treatment. FLV fractions also directly protected treated MuLV from neutralization by specific antibody. FLV fractions enhanced infectivity and protected MuLV of the

following serological types: Gross virus, Friend virus and Moloney virus strain IC. However, the FLV fraction had its enhancing and protective effects only for MuLV which had been passaged through tissue culture; viruses from tumors were not influenced by FLV fractions. The only active fraction of FLV was a fraction of 14,000 daltons which seemed to consist of group-specific antigen I and an associated lipid moiety.

- 4522 HISTORY OF A RHESUS MONKEY ADENOCARCINOMA CONTAINING VIRUS PARTICLES RESEMBLING ONCOGENIC RNA VIRUSES. (E.) Mason, M. M. (Mason Res. Inst., Worcester, Mass.), A. E. Bogden, V. Ilievski, H. J. Esber, J. R. Baker and H. C. Chopra. *J Nat Cancer Inst* 48(5):1323-1331, 1972.

An eight yr old female rhesus monkey developed neoplastic growths near the left nipple, in the left axilla and over the seventh and eighth ribs. Biopsy of the growth located near the nipple showed necrosis; viable portions of the tumor had a trabecular arrangement. Most viable cells were undifferentiated. Subsequent biopsy specimens showed viable polyhedral cells arranged in cords with a suggestion of an acinar formation. The monkey was in continual estrus. Phenesterin therapy produced oncolysis, as indicated by regression in tumor size (54 and 44% regression in two tumors); after phenesterin was discontinued, tumor growth was resumed. Autopsy revealed a widely disseminated tumor which had invaded both breasts and probably originated primarily in the breast and secondarily in the ovary. Small tumor masses were found in the adrenals, pancreas, kidneys, liver and stomach. Large numbers of virus particles, resembling Mason-Pfizer virus, were seen in biopsy material from the primary breast tumor. Serum growth-hormone levels in the tumor-bearing monkey were in the low normal range. Serum-insulin levels were in the high normal range, and serum progesterone levels were normal.

- 4523 INDUCTION OF MURINE C-TYPE VIRUSES FROM CLONAL LINES OF VIRUS-FREE BALB/3T3 CELLS. (E.) Aaronson, S. A. (Nat'l. Cancer Inst., Bethesda, Md.), G. J. Todaro and E. M. Scolnick. *Science* 174(4005):157-159, 1971.

The spontaneous production of C-type virus, in response to bromodeoxyuridine (BrdU), by several clonal lines of mouse BALB/3T3 and BALB/3T12 cells was demonstrated using reverse transcriptase assay and an antibody that specifically inhibits the viral enzyme. Previously, the clonal lines had shown no evidence of C-type virus production. Virion-associated polymerase activity was detected in BALB/3T3 clone A31 the second day following BrdU treatment. Activity reached a maximum in three to four days, then declined until the enzyme was barely detectable by day 14. Enzyme activity was inhibited by viral reverse transcriptase specific antibody. All subclones of A31 also showed inducible enzyme activity. Evidence for the

presence of murine leukemia virus (MLV) was obtained by the XC plaque test following transmission of virus to NIH/3T3 cells. The findings support a model that allows for vertical transmission of viral genome from cell to progeny cell without its extracellular appearance.

4524 TUMOR INDUCTION IN SQUIRREL MONKEYS BY THE ST STRAIN OF FELINE SARCOMA VIRUS. (E.)

Rabin, H. (Nat'l. Ctr. Primate Biol., U. California, Davis), G. H. Theilen, P. S. Sarma, D. L. Dungworth, M. A. Nelson-Rees and R. W. Cooper. *J Nat Cancer Inst* 49(2):441-450, 1972.

The ST strain of feline sarcoma virus (ST-FeSV) induced large undifferentiated sarcomas in two newborn squirrel monkeys after latent periods of 14-15 days. At the site of inoculation, a 2-day-old squirrel monkey developed several tumor masses that regressed, and older squirrel monkeys developed, at inoculation sites, palpable nodules that also regressed. A single 41-day-old talapoin monkey was refractory for tumor induction. The two tumors studied in tissue culture had pleomorphic cells (including multinucleated cells) that grew both in suspension and on the substratum. Both cell lines had essentially normal karyotypes. No virions were seen on ultrastructural examination of cells from either original tumors or early passage cultured cells derived from them. ST-FeSV group-specific (gs) antigen was in cell cultures derived from one of these tumors, which released a cell-transforming and gs antigen-inducing virus for normal cultured feline cells. A viable cell inoculum, prepared from cultured cells derived from this squirrel monkey tumor, induced, in kittens, sarcomas containing cells with feline karyotype. In limited trials, a tumor extract, a first-passage tissue-culture fluid concentrate, and viable fifth-passage cultured cell inocula, all derived from this same tumor, failed to induce progressive tumors in squirrel monkeys. Cultured cells of the second squirrel monkey tumor induced by ST-FeSV did not contain gs antigens and failed to release a cell-transforming or gs antigen-inducing virus. Attempts to rescue the ST-FeSV genome from cells of the gs antigen-negative tumor *in vitro* by cocultivation with cat cells infected with feline leukemia virus were negative.

4525 STRUCTURAL PROTEINS OF ADENOVIRUS-ASSOCIATED VIRUS TYPE 3. (E.) Johnson, F. B. (Nat'l. Cancer Inst., Bethesda, Md.), H. L. Ozer and M. D. Hoggan. *J Virol* 8(6):860-863, 1971.

Adenovirus-associated virus (AAV) type 3H virions were isolated from infected KB cells, purified by CsCl gradient centrifugation and analyzed on SDS-polyacrylamide gels. Three major structural proteins were found with molecular weights of approximately 66,000 (VP1), 30,000 (VP2) and 92,000 (VP3). VP1 was the fastest migrating and most prominent component (80% of total virus protein). Estimates of the number of polypeptide units per virion indicated that AAV-3H contained

6×10^6 daltons of protein. Thus, each virion contained approximately 72 VP1, 8 VP2 and 7 VP3 polypeptides. A minor high-molecular-weight band (117,000) was seen infrequently in gels of SDS-dissociated AAV. Since the band was never seen in urea-dissociated preparations, it probably represented a polymer of one or more of the major peptides.

4526 GENETIC ANALYSIS OF SIMIAN VIRUS 40. IV. INHIBITED TRANSFORMATION OF BALB/3T3 CELLS BY A TEMPERATURE-SENSITIVE EARLY MUTANT. (E.) Robb, J. A. (Nat'l. Cancer Inst., Bethesda, Md.), H. S. Smith and C. D. Scher. *J Virol* 9(6):969-972, 1972.

BALB/3T3 clone A31 mouse cells were absorbed with virions of the temperature-sensitive *ts*101* mutant of SV40 (101 virus) at 33 and 38.5 C (permissive and restrictive temperatures, resp.) Transformation of cells and synthesis of SV40 tumor (T) antigen were observed. There was no difference between normal wild-type and 101 SV40 virion absorption on BALB/3T3 at 33 or 38.5 C. The ability of 101 virions to initiate T antigen synthesis in abortively and stably transformed cells was inhibited 8-20 times at 33 C and 400-500 times at 38.5 C. T antigen synthesis after 101 virion infection was temperature-sensitive. Both abortive and stable transformation of 3T3 cells by 101 virions were inhibited at both 33 and 38.5 C, but neither transformation was temperature-sensitive. Two clones of 101-transformed cells from a 33 C stable transformation assay released rescuable virus at 33, 38 and 40 C. All rescued viruses were similar to the original 101 mutant in temperature sensitivity.

4527 SYNTHESIS OF VIRAL RIBONUCLEIC ACID DURING RESTRICTED ADENOVIRUS INFECTION. (E.)

Fox, R. I. (Albert Einstein Coll. Med., Bronx, N.Y.) and S. G. Baum. *J Virol* 10(2):220-227, 1972.

The mechanism by which simian virus 40 converts the abortive adenovirus type 7 infection of monkey cells into an efficient lytic infection has been investigated. Analysis of ribonucleic acid (RNA) synthesis during unenhanced and enhanced infection of monkey cells has shown that adenovirus RNA synthesized in the abortive infection contains both "early" and "late" sequences. In hybridization competition experiments, early adenovirus RNA from human cells prevented the hybridization of only 20% of the adenovirus RNA transcribed in unenhanced infection. Further, the RNA from unenhanced cells was able to completely block the hybridization of RNA synthesized during enhanced infection. Finally, virus-associated RNA, which is a late RNA transcribed in lytic adenovirus infection, is also produced in the unenhanced infection. A marked deficiency in adenoviral capsid protein synthesis in the unenhanced infection is noted. It is concluded that RNA sequences, which are sufficient to code for the synthesis and assembly of structural proteins of adenovirus are transcribed but are not efficiently translated in the unenhanced adenovirus infection of monkey cells.

- 4528 ROUS VIRUS ABSORPTION BY CELLS NATURALLY RESISTANT TO IT: ELECTRON MICROSCOPE STUDY. (Rus.) Savost'yanov, G. A. (N. N. Petrov Res. Inst. Oncol., Leningrad, USSR), A. M. Dyad'kova, and O. K. Kuznetsov. *Vop Onkol* 18(3):52-56, 1972.

Rous sarcoma virus (RSV; D-5 strain) in culture fluid from infected chick embryo cells was concentrated by ultracentrifugation. Chick embryo cells passaged with various kinds of RSV (RAV-1, RAV-2, Schmidt-Rupin virus) were used as sensitized cells, and skin and muscle cultures from 6-12-week-old human embryos were used as resistant cells. After cells had been incubated from 15-180 min with the virus in an aqueous solution at 37 C, the cell suspension was concentrated by centrifugation, and the resulting deposit was prepared for electron microscope examination. RSV was absorbed by phagocytosis and pinocytosis by the sensitized cells (within 15-60 min) and by the resistant cells (in the first 30 min). The number of virus particles remained unchanged during the 3-hr observation period in the resistant cells, while in the sensitized cells the number of virus particles decreased rapidly within 2 hr since virus particles were incorporated in the infectious process and virus replication phase began. The virus absorbed by the resistant cells does not participate in the infectious process but can be ejected by the cell with the rest of the vacuoles and absorbed again. In the resistant cells, complicated interactions between the membranes of the virion and cell do not take place; the destruction of the virion membrane and the liberation from it of internal nucleoproteins and nucleic acids is inhibited. This explains the inherent resistance of the cells to RSV.

- 4529 INTRACELLULAR FORMS OF ADENOVIRUS DEOXYRIBONUCLEIC ACID. I. EVIDENCE FOR A DEOXYRIBONUCLEIC ACID-PROTEIN COMPLEX IN BABY HAMSTER KIDNEY CELLS INFECTED WITH ADENOVIRUS TYPE 12. (E.) Doerfler, W. (Rockefeller U., New York, N. Y.), U. Lundholm and M. Hirsch-Kauffmann. *J Virol* 9(2):297-308, 1972.

Baby hamster kidney cells (BHK-21) were abortively infected with ^3H -adenovirus 12 (Ad12). Total intracellular DNA from infected cells was extracted and analyzed by the dye-buoyant density method using propidium iodide. Between 2 and 34 hr after infection, 8.2-20.4% of ^3H -labeled intracellular DNA had a density in dye-buoyant gradients which was 0.043-0.085 g/cm³ greater than the density of ^{14}C -labeled Ad12 marker DNA from purified virions. This heavy density DNA (HP fraction) was not seen when viral DNA was extracted from infected cells under conditions in which viral endonuclease was inhibited by 2-mercaptoethanol. The HP fraction DNA did not occur when Ad12 was prevented from absorbing and entering BHK-12 cells. In DNA-DNA hybridization tests, the HP fraction DNA hybridized exclusively with viral DNA. DNA of the HP fraction sedimented at similar rates in neutral and alkaline sucrose gradients. When DNA in the HP fraction was observed under the electron microscope, only linear DNA molecules were seen. By 2 hr after infection of BHK-21 cells with Ad12, equal amounts of HP fraction DNA were found in cell nuclei and cytoplasm. These findings indicate that a protein of cellular origin is

bound in a complex with Ad12 viral DNA in the HP fraction. RNA may also be involved in the DNA-protein complex. HP fraction DNA is only partly sensitive to digestion with deoxyribonuclease.

- 4530 THE COMBINED ACTION OF RAUSCHER LEUKEMIA VIRUS AND LACTIC DEHYDROGENASE VIRUS ON MOUSE LYMPHATIC TISSUE. (E.) Proffitt, M. R. (Oak Ridge Natl. Lab., Tenn.), C. C. Congdon and R. L. Tyndall. *Int J Cancer* 9(1):193-211, 1972.

Specific pathogen-free BALB/c mice were inoculated with animal-passaged Rauscher leukemia virus (APRLV), tissue-culture-passaged RLV (TCRLV), or lactic dehydrogenase virus (LDV); the APRLV was contaminated by LDV. Mice given LDV-contaminated APRLV showed early changes in lymphatic tissues comparable to changes seen in mice given LDV alone. These changes included depletion of small lymphocytes in spleen follicles and proliferation of immunoblasts in mesenteric lymph nodes. Prominent erythroid hyperplasia in the spleen of mice given APRLV, a reaction typical of Rauscher disease, was not seen in mice given LDV alone. Mice given an animal passage of TCRLV (AP-TCRLV), which was relatively uncontaminated by LDV, showed the early erythroid hyperplasia of APRLV-treated mice, but none of the other responses seen in mice given APRLV or LDV. Immunoblast proliferation and lymphocyte depletion in thymus-dependent areas were characteristic of the response to APRLV or LDV, but were not seen in mice given AP-TCRLV. Some changes seen in mice given APRLV or LDV resembled changes associated with stress and mediated by corticosteroid hormones. When LDV was added to AP-TCRLV prior to inoculation, the Rauscher disease response of inoculated mice was enhanced, as measured by increases in spleen weight. Proliferation of lymphoid tissue germinal center cells also followed addition of LDV to AP-TCRLV inocula. The presence of LDV in AP-TCRLV inocula given two days before challenge with sheep erythrocytes decreased primary hemagglutinin titers in recipients to 2-3 logs below titers in mice given APRLV, LDV or AP-TCRLV without LDV added.

- 4531 CROSS PROTECTION *IN VIVO* AGAINST AVIAN SARCOMA VIRUS SUBGROUPS A, B AND C INDUCED BY ROUS-ASSOCIATED VIRUSES. (E.) Meyers, P. (U. Miami Sch. Med., Fla.), M. M. Sigel and H. T. Holden. *J Nat Cancer Inst* 49(1):173-182, 1972.

Chickens were immunized with three biweekly injections of 10⁶ infectious U of Rous-associated virus (RAV), subgroups A, B or C; immunized birds were challenged six wk later with 100 focus-forming U of Schmidt-Ruppin Rous sarcoma virus (RSV) (subgroup B), RSV(RAV-1) (subgroup A), or Prague RSV (subgroup C). Tumor incidence was reduced on day nine after challenge in chickens immunized with RAV-1 (subgroup A); tumor incidence was reduced 94% in chickens challenged with subgroup A virus, 70% in chickens challenged

with subgroup B virus, and 60% in chickens challenged with subgroup C virus. The protective effect of immunization with A virus against challenge with A or B viruses persisted, but the initially less effective protection against subgroup C virus challenge became still less evident. Similar results were seen in chickens immunized with RAV-6 (subgroup B) and challenged with viruses of the three subgroups. Immunization with the B virus protected well against challenge with B or C viruses, but not against challenge with A virus. Immunization with RAV-49 (subgroup C) protected well against challenge with B and C viruses but only slightly against challenge with A viruses. This cross protection effect was not dependent on humoral antiviral neutralizing antibody, since resistant birds had antibodies only to the immunizing virus. The cross-protective effect was thought to be mediated by cellular immunity against common viral antigens or common virus-induced antigens.

4532 FELINE FIBROSARCOMA VIRUS: QUANTITATIVE FOCUS ASSAY, FOCUS MORPHOLOGY AND EVIDENCE FOR A "HELPER VIRUS". (E.) McDonald, R. (Rush-Presbyterian-St. Luke's Med. Ctr., Chicago, Ill.), L. G. Wolfe and F. Deinhardt. *Int J Cancer* 9(1):57-65, 1972.

Feline muscle, embryo and tongue tissue cultures, and marmoset kidney, skin and muscle cultures, were inoculated with Snyder-Theilen feline sarcoma virus (FeSV) or Gardner FeSV; infected cultures were overlaid with agar and re-fed three to five days later with liquid media. FeSV in infected cultures was assayed by focus formation. Higher titers of FeSV of both strains were found in feline cells than in marmoset cells (e.g., titers of 4,129 compared with 929 focus-forming U/ml). Snyder-Theilen FeSV grown in feline or marmoset cells, and Gardner FeSV grown in feline cells, generally induced foci of two morphological types foci consisting of round cells and foci consisting of a loose meshwork of round and fusiform cells. These different morphological types of foci were also seen in two morphological types of clone of FeSV-infected cells. Thermal stability experiments suggested that the morphological differences between foci were virus-dependent. When feline cell cultures were inoculated with Snyder-Theilen FeSV beyond the end point of focus induction, transformation by subsequent challenge inocula of this FeSV was inhibited. This indicated a ten- to 100-fold excess of interfering helper virus in this system.

4533 ERYTHROID NATURE OF THE RESPONSE TO FRIEND LEUKEMIA VIRUS INFECTION IN MICE. (E.) Stephenson, J. R. (U. Toronto, Fac. Med., Ontario, Canada), A. A. Axelrad and D. L. McLeod. *J Nat Cancer Inst* 48(2):531-539, 1972.

SIM/Mc and C3H/Bi mice were infected with a "polycythemic strain" of Friend virus (FV); prior to FV in-

fection, the mice had been subjected to ex-hypoxia to suppress hemoglobin synthesis. FV infection returned hemoglobin synthesis to normal in the plethoric mice. Blood erythrocyte concentration was increased in FV-infected SIM mice but was relatively unaffected in FV-infected C3H/Bi mice. FV increased the number of circulating nucleated cells in blood of both strains of mouse; increases were threefold in SIM and sevenfold in C3H/Bi mice. FV-transformed, tumor colony-forming cells were detected in the blood of C3H/Bi mice. Heme synthesis was increased in blood of FV-infected mice. This increase in heme synthesis was found to be due not only to erythrocyte activity, but also to intensive heme synthesis in a population of nucleated cells having a modal sedimentation velocity identical to that of FV-transformed cells but twice that of erythrocytes.

4534 STIMULATION OF DNA SYNTHESIS AND ENHANCEMENT OF MURINE SARCOMA VIRUS REPLICATION IN MOUSE EMBRYO CELLS BY SV40. (E.) Baker, R. S. U. (Sch. Med., Perth, Australia), P. J. Simons and B. J. Rankin. *J Gen Viro* 14:115-117, 1972.

The effect of wild-type simian virus (SV40) on DNA synthesis in cultured BALB/c mouse embryo cells is reported. The cultured cells were passed every three days at a concentration of 3×10^4 cells/cm² in Eagle's Minimum Essential Medium supplemented with 10% inactivated calf serum. Passage eight cells in an amitotic phase of negligible growth were infected with SV40 or murine sarcoma virus-Harvey (MSV-H), or with both SV40 and MSV-H. After 24-hour incubation in ³H-thymidine, the cells were processed for autoradiography and the proportion of cells synthesizing DNA was determined. Infection with SV40 resulted in a rapid increase in the number of cells incorporating ³H-thymidine and a concomitant increase in cell numbers. Sixty percent of infected cells were synthesizing DNA within 48 hr; none showed altered morphology. Cells infected with MSV-H alone did not undergo morphologic transformation, DNA synthesis or subsequent cell replication. Cultures infected with both SV40 and MSV-H showed extensive transformation to densely staining spindle cells. Fluids were collected from all cultures two and four days after infection and were tested for MSV-H by plaque assay. Among control cultures and cultures infected with SV40 or MSV-H alone, only four-day fluid from MSV-H-infected cells contained MSV-H (0.25×10^2 focus-forming units/ml). MSV-H titers in fluids from two- and four-day SV40 plus MSV-H cultures were 1.2×10^2 and 3.4×10^2 focus-forming units/ml, resp. These results indicate that MSV-H requires host cell DNA synthesis for successful infection of a cell, and that this is provided by SV40 infection.

4535 ISOLATION OF TEMPERATURE-SENSITIVE MUTANTS OF MURINE LEUKEMIA VIRUS. (E.) Stephenson, J. R. (Nat'l. Cancer Inst., Bethesda, Md.). R. K. Reynolds and S. A. Aaronson. *Virology* 48(3):749-756, 1972.

Kirsten murine leukemia viruses (KiMuLV) growing in NIH/3T3 mouse cells were mutagenized by treatment with 5-bromodeoxyuridine (BrdU) or *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (NTG). A total of 407 NTG-mutagenized KiMuLV-infected clones, and 410 BrdU-treated infected clones, were screened by a microtiter technique for the presence of temperature-sensitive (ts) mutants. Twenty-eight of the NTG-treated clones and 13 of the BrdU-treated clones harbored potential ts mutants, as evidenced by inability to induce syncytia on rat tumor cells (XC) at 31 C (a nonpermissive temperature). Of the 41 potential ts mutant clones, nine (two from BrdU- and seven from NTG-treated clones) were subsequently shown to be ts mutants. Each of the nine ts mutants was investigated to quantitate rates of spontaneous reversion at a permissive temperature. The reversion rates for each of the ts mutants were very low.

- 4536 RESCUE OF EPSTEIN-BARR VIRUS FROM SOMATIC CELL HYBRIDS OF BURKITT LYMPHOBLASTOID CELLS. (E.) Glaser, R. (Milton S. Hershey Med. Ctr., Pennsylvania St. U., Hershey) and F. Rapp. *J Virol* 10(2):288-296, 1972.

A Burkitt lymphoblastoid cell line, P3J-HR-1, was fused to a human sternal marrow cell line, D98/AH-2, using inactivated Sendai virus. The D98/HR-1 hybrid cells were larger than either parental line and grew in multilayered foci. Testing of somatic cell hybrids by direct and indirect immunofluorescence showed no evidence of virus-specific antigens. However, both virus-specific markers and virus particles could be induced by exposing hybrid cells to 5-iododeoxyuridine. These data indicated that the Epstein-Barr virus genome can be transferred from a lymphoblastoid cell to another cell type during cell hybridization, that the viral genome can persist in hybrids for a long period of time, and that virus synthesis can be induced in the heterokaryons.

- 4537 TRANSFORMATION OF GUINEA PIG EMBRYO CELLS BY A MURINE SARCOMA VIRUS. (E.) Rhim, J. S. (Microbiol. Assoc., Bethesda, Md.), C. F. Demoise, F. G. Duh and H. Y. Cho. *Virology* 48(3):841-843, 1972.

Cultured guinea pig embryo cells were infected with the Kirsten murine sarcoma virus (Ki-MSV). Foci of morphologically transformed cells began to appear 15-20 days after infection. Transformed cells continuously released virus, and cell-free preparations from these cells were able to produce similar altered foci in NIH Swiss mouse, rat and guinea pig embryo cells. The transformed cells also contained high titers of gs antigen characteristic of the murine sarcoma-leukemia virus group. Attempts to transform guinea pig embryo cells with the Moloney and Harvey isolates of MSV or with the Theilen strain of feline sarcoma virus were unsuccessful.

- 4538 HERPESVIRUS SAIMIRI IN MARMOSET-MOUSE HYBRID CELL LINES. (E.) Periman, P. (Natl. Cancer Inst., Bethesda, Md.), S. Tyrrell and A. S. Rabson. *J Nat Cancer Inst* 49(2):387-393, 1972.

Marmoset-mouse hybrid cell lines were derived from fusion of marmoset lymphoid cells (MLC-1 line) with 8-azaguanine-resistant murine adenocarcinoma cells (RAG line) by use of Sendai virus and growth in aminopterin-containing medium. Cytogenetic studies of the hybrid lines showed the cells contained both mouse and marmoset chromosomes. Whereas the MLC-1 cells released small amounts of virus into the supernatants and between 0.1 and 1% of these cells released *Herpesvirus saimiri* on contact with vero cells, the hybrid cells released no virus into the supernatants and between 0.01 and 0.09% of these cells released virus on contact with vero monolayers. In the hybrid cell lines the absence of virus in the supernatants and decreased number of cells plating as infectious centers suggest either that the mouse components inhibit the expression of the *H. saimiri* genome, or that replication depends on MLC-1 genes which have been lost, or that the virus itself was lost from many of the hybrid cells. The number of cells yielding virus decreased as the hybrid lines were grown in medium free of aminopterin. This was associated with loss of marmoset chromosomes, which suggests the virus in the MLC-1 cells may be in some way closely associated with the chromosomes.

- 4539 ISOLATION AND CHARACTERIZATION OF SIMIAN VIRUS 40 RIBONUCLEIC ACID. (E.) Weinberg, R. A. (Weizmann Inst. Sci., Rehovot, Israel), S. O. Warmaar and E. Winocour. *J Virol* 10(2):193-201, 1972.

Deoxyribonucleic acid-ribonucleic acid (RNA) hybridization in formamide was used to isolate simian virus 40-specific RNA. Early in the lytic cycle, a 19S viral RNA species was observed. Late in the lytic cycle, 16S and 19S viral species were found. The 16S and 19S species of viral RNA were localized in the cytoplasm. High-molecular-weight heterogeneous RNA, containing viral sequences, was isolated from the nuclear fraction of infected cells late in the lytic cycle. This RNA may contain nonviral sequences linked to viral sequences. The formamide hybridization technique can be used to isolate intact late lytic viral RNA which is at least 99% pure.

- 4540 TEMPERATURE-DEPENDENT TRANSFORMATION OF CELLS INFECTED WITH A MUTANT OF BRYAN ROUS SARCOMA VIRUS. (E.) Bader, J. P. (Natl. Cancer Inst., Bethesda, Md.). *J Virol* 10(2):267-276, 1972.

Chick embryo cells infected with a mutant (Ta) of the Bryan high-titer strain of Rous sarcoma virus (RSV-BH) are morphologically transformed at 36 C but appear similar to uninfected cells at 41 C. When cells infected with RSV-BH-Ta are switched from

1 to 36 C, morphological changes characteristic of transformation are observable within 10 min. The transformation is reversible; cells shifted from 36 to 41 C have been observed to lose their transformed morphology within 1 hr. The transformation after a shift in temperature is unaffected by inhibition of deoxyribonucleic acid (DNA), ribonucleic acid (RNA), or protein synthesis, demonstrating that the proteins involved in the morphological change are already present. Transformed cells infected with RSV-BH or RSV-BH-Ta take up hexose and synthesize hyaluronic acid at higher rates than uninfected cells or RSV-BH-Ta-infected cells grown at 41 C. However, inhibition of either protein or RNA synthesis, but not DNA synthesis, prevented the induction of increased hexose uptake and hyaluronic acid synthesis after a shift of RSV-BH-Ta-infected cells from 41 to 36 C. Therefore, these biochemical changes are secondary to a more basic change responsible for morphological transformation.

541 STRAND ORIENTATION OF SIMIAN VIRUS 40 TRANSCRIPTION IN PRODUCTIVELY INFECTED CELLS. (E.) Lindstrom, D. M. (Salk Inst. Biol. Stud., San Diego, Calif.) and R. Dulbecco. *Proc Nat Acad Sci USA* 69(6): 517-520, 1972.

SC-1 cells were infected with SV40. Eight days after infection, SV40 DNA was extracted from infected cells and annealed with highly asymmetric complementary RNA (cRNA) synthesized from SV40 DNA by an RNA polymerase of *E. coli*. The results indicated that early and late SV40 RNA's were transcribed *in vivo* from opposite strands of the SV40 DNA molecule, that cRNA, synthesized by *E. coli*, was transcribed from the same strand as the early SV40 RNA, and that this cRNA was complementary to the late SV40 RNA.

542 GENETIC ANALYSIS OF SIMIAN VIRUS 40. III. CHARACTERIZATION OF A TEMPERATURE-SENSITIVE MUTANT BLOCKED AT AN EARLY STAGE OF PRODUCTIVE INFECTION IN MONKEY CELLS. (E.) Robb, J. A. (Natl. Inst. Arthritis Metab. Dis., Bethesda, Md.) and R. G. Martin. *J Virol* 9(6):956-968, 1972.

CV-1 cells, a cloned subline of CV-1 monkey cells, were inoculated with the *ts*101* (101) temperature-sensitive mutant of SV40. 101 virions adsorbed as efficiently as nonmutant wild-type SV40 to inoculated cells at restrictive (40-41 C) as well as at permissive (30-33 C) temperatures. 101 virions also penetrated cells normally at restrictive temperatures (i.e., they lost sensitivity to neutralizing antibody after adsorption to cells). At restrictive temperatures, the 101 virions were unable to induce cellular DNA synthesis or synthesis of viral DNA and the viral antigen. SV40-specific tumor antigen synthesis and SV40 U-antigen synthesis were also inhibited in 101 cells at the restrictive temperature. First cycle tumor- and viral-antigen synthesis after infection of cells with 101 DNA were normal at the restrictive temperature, but the resulting progeny virus were

as temperature-sensitive as their 101 parents. 101 virions did not complement or inhibit other temperature-sensitive SV40 mutants or wild-type virions. The affected protein in 101 virions may be a regulatory structural protein, perhaps a core protein, that interacts with the DNA of the virions.

4543 STUDIES OF THE MECHANISM OF ENHANCEMENT OF HUMAN ADENOVIRUS INFECTION IN MONKEY CELLS BY SIMIAN VIRUS 40. (E.) Baum, S. G. (Albert Einstein Coll. Med., Bronx, N.Y.), M. S. Howitz and J. V. Maizel, Jr. *J Virol* 10(2):211-219, 1972.

The defect which prevents human adenovirus replication in monkey cells and the mechanism whereby this restriction is overcome by coinfection with simian virus 40 (SV40) have been studied. Adenovirus capsid proteins are not synthesized efficiently in monkey cells in the absence of SV40. Adenovirus "enhancement" by SV40 was found to be the product of increased efficiency of replication by a small percentage of cells. This enhancement effect apparently occurred only when SV40 and adenovirus infected the same cells. These findings suggest that the replicative block occurs prior to virion assembly, possibly at the post-transcriptional level.

4544 RAT LEUKEMIA DERIVED 9H VIRUS (9HV). II. RESPONSE OF RATS TO LOW DOSES OF VIRUS. (E.) Bergs, V. V. (U. Miami Sch. Med., Florida), T. M. Scotti and M. Bergs. *Proc Soc Exp Biol Med* 139(2):535-539, 1972.

Studies of the growth pattern of 9H virus (9HV) in the liver of W/FU rats revealed that i.p. inoculation of newborn rats, free of maternal antibody to 9HV, with low doses of this virus resulted in a gradual increase of viral progeny (assayed by hemagglutinin inhibition tests on W/FU embryo cells) that reached its peak by day 10. This was followed by a decrease in virus titer accompanied by a gradual increase of serum antibody titer to the virus. Intracellular inclusions in liver cells were noted at day 6. Viral hepatitis, including cytopathic changes and inflammatory cells, and definite peliosis hepatis became evident at day 8 to 10. The thymus and spleen of these animals showed atrophy grossly and histologically. Rats inoculated with 9HV components (9HV-A and 9HV-B) showed a similar pattern of response, except that peliosis hepatis was not conspicuous in rats inoculated with 9HV-B. Intracerebral inoculation of low doses of 9HV resulted in virus multiplication in both brain and liver and in the development of hepatitis and peliosis hepatis. No significant brain lesions were apparent in these animals, indicating cytotropism of this virus in regard to its cytopathic effect in the intact rat. Weanling rats free of antibody to 9HV and inoculated with high doses of the virus failed to develop any disease, indicating an age-dependent resistance to 9HV.

- 4545 INFECTIOUS MONONUCLEOSIS AND ACUTE LEUKEMIA. (Sp.) Sackmann Muriel, F. (Children's Hosp. Buenos Aires, Argentina) and J. A. Penalver. *Sangre* 16(4):403-410, 1971.

Two cases of infectious mononucleosis (IM) and acute leukemia (AL) occurring in the same patient are reported. Both diseases were diagnosed simultaneously in a 2-year-old child and 10 month-old infant; IM was also ascertained in an 8-year-old child during prednisone and vincristine treatment of a relapse of AL. In reviewing published information on 11 related cases, no evidence of a time relationship between the occurrence of the two diseases could be found. Acute leukemia does not seem to alter the immunological response to IM and a common etiological agent for the two diseases appears unlikely.

- 4546 SEQUENCE HETEROGENEITY IN CLOSED SIMIAN VIRUS 40 DEOXYRIBONUCLEIC ACID. (E.) Tai, H. T. (Norman W. Church Lab. Chem. Biol., California Inst. Tech., Pasadena), C. A. Smith, P. A. Sharp and J. Vinograd. *J. Virol* 9(1):317-325, 1972.

Singly nicked closed circular SV40 DNA was denatured in NaOH, and the heteroduplex molecules of viral DNA formed by the self-annealing of the denatured DNA were observed by formamide-protein film electron microscopy. DNA was prepared from SV40 grown at high and low multiplicities of infection (HM and LM DNA, resp.) Undenatured DNA showed a narrow length distribution and otherwise appeared homogeneous in size. Observations of heteroduplexes in LM DNA indicated that 2.5% of LM DNA molecules contained deletions which, together with DNA sequence substitutions, caused single-stranded loops to appear in the DNA. No detectable substitution loops were seen in LM DNA. Undenatured HM DNA, however, showed a high frequency of heteroduplexes containing deletions or substitutions (11-13% of molecules with deletions and 7-12% with substitutions). Deletions and substitutions appeared to occur in separate molecules. Length measurements indicated that the molecules were from true sequence substitutions, and not from adjacent or overlapping deletions. More than 80% of heteroduplexes with substitutions were shorter than native SV40 DNA; substituted sequences in these DNA's ranged from 5-50% of the SV40 length (mean = 20% of SV40 length).

- 4547 SURFACE CHANGES OF HUMAN CELLS PRODUCTIVELY INFECTED WITH HUMAN ADENOVIRUSES. (E.) Salzberg, S. (St. Louis U. Sch. Med., Missouri) and H. J. Raskas. *Virology* 48(3):631-637, 1972.

Productive infection of human embryonic kidney (HEK) cells with a group C adenovirus (type 2) resulted in surface changes that were detected as increased agglutination in the presence of concanavalin A (Con A). Agglutination increased as the infection progressed, with maximum response to Con A occurring by 18 hr. Treatment with cytosine arabinoside either for the entire infection or beginning 8 hr

after infection prevented the surface alterations. In contrast to the agglutination produced by adenovirus 2, infection with a group A adenovirus (type 12) did not cause a changed response to Con A. However, infection with two cytotoxic mutants derived from adenovirus 12 resulted in membrane changes detectable by Con A. These findings demonstrate that specific viral gene functions are required for the surface changes occurring during productive infection of adenoviruses. Since the cytotoxic mutants are nononcogenic, the ability to produce surface changes during productive infection seems to be unrelated to the oncogenicity of the virus.

- 4548 GENETIC RELATEDNESS OF TYPE 1 AND TYPE 2 HERPES SIMPLEX VIRUSES. (E.) Kieff, E. (Dept. Biol. Sci., U. Chicago, Ill.), B. Hoyer, S. Bachenheimer and B. Roizman. *J Virol* 9(5):738-745, 1972.

The extent of homology between herpes simplex virus 1 and 2 (HSV-1 and HSV-2) DNA was measured by determining the relative rate of hybridization of ³H- or ¹⁴C-thymidine-labeled HSV-1 and HSV-2 DNA to excess unlabeled HSV-1 or HSV-2 DNA immobilized on filters (liquid filter annealing) or in solution (liquid annealing). Approximately 40% of HSV-1 and HSV-2 DNA was homologous at hybridization temperatures 25 C below the melting temperature (T_m) of HSV DNA (liquid-filter annealing). Lowering the temperature to 34 C below the T_m increased the extent of homology to 46% (liquid annealing). The extent of base-pairing in HSV-1-HSV-2 heteroduplex DNA was determined by thermal chromatography on hydroxyapatite. Heteroduplexes of HSV-1 and HSV-2 DNA eluted in a single peak whose midpoint (Te₅₀) was 10 C below that of the homoduplex. Conspicuously absent were heteroduplexes that eluted at more than 15 C below the Te₅₀ of the homoduplex. The data suggest the existence of a variable region of HSV DNA (54%) with very little, if any, homology and an invariable region (46%) with relatively good (85%) matching of base pairs.

- 4549 EVIDENCE FOR A NEW BIOSYNTHETIC PATHWAY OF SPHINGOMYELIN IN SV40 TRANSFORMED MOUSE CELLS. (E.) Diringer, H. (Max-Planck Inst. Virus Res., Tübingen, West Germany), W. D. Marggraf, M. A. Koch and F. A. Anderer. *Biochem Biophys Res Commun* 47(6):1345-1352, 1972.

Sphingomyelin metabolism was studied in replicating SV40-transformed mouse fibroblasts by ³²P-orthophosphate plus ³H-choline pulse-chase experiments. Cells were pulse labeled with both substances for 24 hr and then chased. At given times during the chase, cell aliquots were taken and the lipids were extracted. The individual phospholipids were separated by two-dimensional thin-layer chromatography. The proportion of ³²P to ³H incorporated into both lecithin and sphingomyelin was constant at all times, indicating that the radioactivity was probably incorporated into these two lipids as ³²P-phosphoryl-³H-choline. The kinetics of incorporation, however,

differed between the two lipids. The peak of radioactivity in the lecithin fraction was reached within four hr after the beginning of the chase and thereafter declined slightly, whereas the peak radioactivity in the sphingomyelin fraction was not reached until 20 hr after the start of the chase. Further analysis of the labeling kinetics of the two phospholipids suggested that sphingomyelin was synthesized by transfer of phosphorocholine from lecithin to free or N-acylated sphingosine. It was concluded that previously described biosynthetic pathways, in which sphingomyelin was formed either by transfer of phosphorocholine from CDP-choline to N-acylsphingosine or by the direct acylation of sphingosylphosphorylcholine, were of only minor importance in the present system.

- 4550 PROPERTIES OF A MURINE SARCOMA VIRUS ISOLATED FROM A TUMOR ARISING IN AN NZW/NZB F₁ HYBRID MOUSE. I. ISOLATION AND PATHOLOGY OF TUMORS INDUCED IN RODENTS. (E.) Gazdar, A. F. (Natl. Cancer Inst., Bethesda, Md.), H. C. Chopra and P. S. Sarma. *Int J Cancer* 9(1):219-233, 1972.

A spontaneous sarcoma developed by a New Zealand white x New Zealand black (B/W) F₁ mouse was studied; the tumor arose s.c. in the left flank and consisted of elongated spindle-shaped cells. It could not be passaged more than three times *in vivo* in B/W or BALB/c mice. A sarcoma virus was isolated from transplanted sarcoma tissue and inoculated i.m. into mice, rats, hamsters and Mastomys. Virus inoculation produced a high incidence of sarcomas in these species; virus-induced tumors sometimes regressed in mice, but did not regress in other species. Virus-induced tumors could be transplanted into recipients of the four species. Transplanted tumors regressed in many cases in mice and hamsters. Virus-induced mouse tumors were sarcomas comprised of spindle cells and many inflammatory cells and showing a prominent angiomatous component. Splenomegaly developed in 80% of virus-inoculated B/W mice; spleens of these mice showed destruction of normal architecture and replacement of normal cells by angiomatous tissue; fibrous and inflammatory changes were also seen in mouse spleens. Lymphoid tissues of tumor-bearing mice also showed striking changes. Virus-induced hamster tumors consisted of undifferentiated polygonal cells, while tumors of rats and Mastomys consisted of thin-walled blood vessels infiltrated with polymorphonuclear leukocytes. Under the electron microscope, both virus-induced and transplanted sarcomas showed many C-type virus particles which resembled murine leukemia-sarcoma viruses. In complement fixation tests with murine leukemia-sarcoma group-specific (gs) antisera and tumor homogenates, the murine leukemia-sarcoma virus gs antigen was demonstrated.

- 4551 ISOLATION AND CHARACTERIZATION OF A PROTEIN THAT STIMULATES DNA SYNTHESIS FROM AVIAN MYELOBLASTOSIS VIRUS. (E.) Leis, J. P. (Albert

Einstein Coll. Med., Bronx, N.Y.) and J. Hurwitz. *Proc Nat Acad Sci USA* 69(8):2331-2335, 1972.

A heat-labile, nondialyzable factor, which stimulates viral RNA dependent DNA polymerase, was isolated during the purification of the avian myeloblastosis virus enzyme. Polymerase activity was purified by ammonium sulfate precipitation followed by two elutions from phosphocellulose columns. The protein factor, which was eluted at a low salt concentration from the second column, was inactivated by heating at 100 C for four min or by pronase treatment, but was not affected by incubation with nuclease S1. The protein stimulated the rate of AMV RNA-primed DNA synthesis by up to eight-fold when added to the purified AMV polymerase fraction. It also stimulated AMV polymerase-directed repair of ³H-labeled λ DNA which had 32% of its total nucleotides removed with exonuclease III. The factor was specific in this system for the purified AMV polymerase and was not able to stimulate other bacterial, mammalian or viral polymerases. It was also specific for DNA synthesis primed with AMV-RNA only. In the presence of stimulatory protein, the AMV polymerase was able to initiate synthesis from single-strand breaks in native DNA.

- 4552 CELL SURFACE GLYCOSYL TRANSFERASES AND ACCEPTORS IN NORMAL AND RNA- AND DNA-VIRUS TRANSFORMED FIBROBLASTS. (E.) Bosmann, H. B. (U. Rochester Sch. Med. Dent., N.Y.). *Biochem Biophys Res Commun* 48(3):523-529, 1972.

Glycosyl transferases and transferase acceptors have been demonstrated on the membrane surface of normal 3T3 mouse fibroblasts and on 3T3 cells transformed by murine sarcoma virus (MSV), polyoma virus (PY) and Rous sarcoma virus (RSV). The presence of enzyme and acceptor was determined by the ability of cells to stimulate the transfer of monosaccharide from isotopically labeled nucleotide diphosphate monosaccharide to acid insoluble material. All three transformed cell lines, when confluent, had enzyme and/or acceptor sites in levels two to four times those present in confluent 3T3 cultures. However, in cells from sparse cultures, the reaction was essentially the same in both the normal and transformed cells. Using exogenous acceptors, elevated surface levels of some glycoprotein: glycosyl transferases were demonstrated in the transformed cells. These results are consistent with the hypothesis that glycosyl transferases may function as bridge or combination molecules in cell-cell adhesion phenomena and contact inhibition.

- 4553 INTERFERON INDUCERS: ENHANCEMENT OF VIRAL ONCOGENESIS IN MICE AND RATS. (E.) Gazdar, A. F. (Natl. Cancer Inst., Bethesda, Md.), A. D. Steinberg, G. F. Spahn and S. Baron. *Proc Soc Exp Biol Med* 139(4):1132-1137, 1972.

Pretreatment with several interferon inducers en-

hanced virus-induced sarcomas and leukemias in mice and rats. Pretreatment with a single s.c. dose of polyI·polyC or polyA·polyU, a single oral dose of tilorone, a single i.v. dose of Newcastle disease virus (NDV) or a single i.p. dose of pyran copolymer 24 hr prior to i.m. inoculation of murine sarcoma virus (MSV) significantly enhanced tumor induction in weanling AL/N mice and suckling Osborne-Mendel rats. The enhancement was manifested by a shorter latent period to tumor appearance, higher incidence of tumors, larger mean tumor size, and longer regression time as compared with control animals injected with MSV alone. Injection of polyI·polyC simultaneously with MSV also enhanced tumor induction. However, injection either 48 hr prior to or 24 hr after MSV inoculation had no effect on the tumors. The enhancing effect of polyI·polyC was strain dependent. Pretreatment enhanced tumor induction in AL/N mice, (BALB/c x AL/N) F₁ mice, NZW mice and A/J mice but had no effect in BALB/c or A/He mice. Sex differences were not seen in polyI·polyC enhancement and the effect on MSV tumors did not correlate with the H-2 type or the allotypes of the Fv-1 locus, which controls the sensitivity to murine leukemia viruses. No correlation was observed between polyI·polyC-mediated tumor enhancement and the induced levels of circulating interferon. Pretreatment of AL/N mice with potent interferon preparations 18 hr prior to MSV inoculation enhanced tumor development but had no effect on mean tumor size or tumor regression time. Pretreatment of BALB/c and C3H mice with a high dose of interferon or with polyI·polyC enhanced Rauscher leukemia virus (RLV)-induced splenomegaly, but lower doses of interferon, tilorone and NDV had no significant effect. Pretreatment with statolon s.c. had no effect on MSV tumor induction in AL/N or BALB/c mice. There was no correlation between the enhancement of humoral immunity by polyI·polyC and its enhancement of MSV-induced tumors.

- 4554 DNA COPIES OF VIRAL RNA IN RAT CELLS TRANSFORMED BY ROUS SARCOMA VIRUS (RSV). (E.) Harel, L. (Inst. Sci. Res. Cancer, Villejuif, France), J. Harel and G. Frezouls. *Biochem Biophys Res Commun* 48(4):796-801, 1972.

DNA preparations from Rous sarcoma virus (RSV)-transformed XC-cells and from normal rat liver cells were tested for the presence of copies of the RSV genome by hybridization to ³²P-labeled viral 70S RNA. At least 50% of the input ³²P-labeled 70S viral RNA annealed with DNA from the transformed XC-cells, while only two to three percent annealed with DNA from normal rat liver cells. The amount of viral RNA annealing to XC-cell DNA indicated that XC-cells contain one or two viral genome copies per tumor cell genome. These results are consistent with the provirus theory of viral oncogenesis.

- 4555 VIRAL AND CELLULAR ANTIGENS OF MURINE LEUKEMIAS AND MYELOMAS. SEROLOGICAL ANALYSIS BY IMMUNOELECTRON MICROSCOPY. (E.) Aoki, T.

(Sloan-Kettering Inst. Cancer Res., New York, N.Y.) and T. Takahashi. *J Exp Med* 135(3):443-457, 1972.

Immunoelectron microscope studies were used to detect H-2, θ , Ly-A and Ly-B antigens on two mouse leukemia cells: the E δ G2 leukemia induced by Gross virus and carrying the Gross cell surface antigen (GCSA), and the spontaneous AKR leukemic K36 ascites cells, also positive for GCSA. H-2^b, θ -C3H and Ly-A.2 antigens were seen on the E δ G2 cell surface; Ly-B.2 was not demonstrable. One eighth of budding and extracellular murine leukemia virus (MuLV) virions in these cells showed θ -C3H antigen; H-2^b, Ly-A.2 and Ly-B.2 were not detected on any virions in E δ G2 cells. H-2^k and Ly-B.1 antigens were detected on K36 cell surfaces; θ -AKR and Ly-A.2 antigens were not detectable. MuLV virions in K36 cells showed H-2^k antigens on their envelopes in 25% of cases. θ -AKR, Ly-A.2 and Ly-B.1 antigens were lacking on MuLV virions in K36 cells. In related studies, an additional viral envelope antigens was detected on virions produced by the mouse myeloma MOPC-70A cells in tests for the differentiation alloantigen (PC). Based on immunoelectron microscopic analysis of the antigen, MOPC-70A myeloma virus is a distinct MuLV subtype.

- 4556 MORPHOLOGY OF SIMIAN FOAMY VIRUSES, WITH PARTICULAR REFERENCE TO VIRUS ISOLATED FROM SPONTANEOUS TUMOR OF A RHESUS MONKEY. (E.) Chopra, H. C. (Nat. Inst. Neurol. Dis. Stroke, Laurel, Md.), J. J. Hooks, M. J. Walling and C. J. Gibbs, Jr. *J Nat Cancer Inst* 48(2):451-463, 1972.

Simian foamy virus (SFV) types 1-7 propagated in vero green monkey kidney cells and human embryo kidney cells were observed under the electron microscope. The seven serotypes were compared with one another and with the Mason-Pfizer monkey virus (C(M-PMV)). Cell cultures inoculated with SFV developed cytopathic changes characterized by the formation of syncytia and dilation of endoplasmic reticulum. The different strains differed slightly in their size and surface projections. In all cases, however, virions consisted of an outer envelope with projections and a ring-shaped inner component. The internal component appeared in the cytoplasm and by budding process became enveloped by the cell membrane. In contrast, the C(M-PMV) virus lacked surface projections and consisted of an inner dense nuclei. The foamy virus types were also antigenically distinct from C(M-PMV): none was neutralized by anti-C(M-PMV) sera and no C(M-PMV) antigens were detected in SFV-infected cells by immunofluorescence testing. A potential oncogenic role is indicated for the foamy viruses in view of their morphologic resemblance to known oncogenic RNA viruses.

- 4557 THE ISOLATION AND CHARACTERIZATION OF PLASMA MEMBRANE FROM CULTURED CELLS. IV. THE CARBOHYDRATE COMPOSITION OF MEMBRANES ISOLATED FROM ONCOGENIC RNA VIRUS-CONVERTED CHICK EMBRYO

FIBROBLASTS. (E.) Perdue, J. F. (McArdle Lab. Cancer Res., U. Wisconsin, Madison), R. Kletzien and V. L. Wray. *Biochem Biophys Acta* 266(2):505-510, 1972.

Cell membrane fractions were isolated by density gradient centrifugation of homogenates of cultured chick embryo fibroblasts converted by avian sarcoma viruses, morph^f Fujinami virus and a mutant of this virus, morph^r Fujinami virus. Membrane fractions were concentrated in sucrose at a density of 1.058 ± 0.001 (A' band of morph^f-converted cells) and 1.074 ± 0.004 (A' band of morph^r-converted cells). The membranes in the B' band from cells converted by either virus were both concentrated at density of 1.11. Estimates of sialic acid content in the membrane fractions were 75 nmoles/mg protein in the A' band from morph^f-converted cells and 64 nmoles/mg protein in the A' band from morph^r-converted cells. Sialic acid levels were 50% higher in uninfected cells. Neutral sugar levels in the A' and B' band membranes from morph^f-converted cells were 235 and 152 $\mu\text{g}/\text{mg}$ protein, the same as recently reported for uninfected cells. The morph^r-converted cells had 40% more neutral sugar (331 $\mu\text{g}/\text{mg}$ protein) in the A' band than did uninfected cells. This value was similar to that reported for RBA-virus-transformed cells. An analysis of the amino sugar content (0.13-0.19 $\mu\text{g}/\text{moles}/\text{mg}$ protein) of the cell membranes in the A' and B' bands from uninfected fibroblasts and fibroblasts infected with leukosis virus (RAV-49), or infected and converted by sarcoma virus RBA and morph^f and morph^r Fujinami, did not establish compositional differences which could be related to morphological cell shape or virus conversion. The most consistent finding was the decrease in sialic acid content of membranes from the cells converted by the oncogenic viruses (RBA, morph^f and morph^r Fujinami). Since this decrease also did not correlate with cell shape and was not observed in leukemia virus-infected cells, it represents a fundamental alteration in membrane chemistry paralleling a loss of the fibroblasts' controls of growth and multiplication.

4558 PATTERNS OF GLUCOSE METABOLISM IN NORMAL AND VIRUS-TRANSFORMED CHICK CELLS IN TISSUE CULTURE. (E.) Bissell, M. J. (Dept. Molec. Biol., U. California, Berkeley), C. Hatie and H. Rubin. *J Nat Cancer Inst* 49(2):555-565, 1972.

Chick embryo cells, normal and transformed by Bryan, Schmidt-Ruppin or Rous-associated sarcoma viruses (RSV), were grown at cell densities ranging from "sparse" (6×10^5 cells/60 mm dish) to "dense" (5.5×10^6 cells/dish); glucose uptake, formation of lactic acid, and formation of CO_2 , were observed in cultures. When ^{14}C -glucose was added to normal cells at less than limiting concentrations ($<0.5 \text{ mM}$), the ratio of lactate to glucose was always higher in dense than in sparse cultures. Although the absolute rate of lactate production decreased as cells became more crowded, the ratio of lactate produced per glucose used increased. In normal cells, CO_2 production and CO_2 : glucose ratio decreased with increasing cell density. Thus the lactate: CO_2 ratio increased with increasing

cell density (i.e., more glucose was channeled through the glycolytic than through the aerobic pathways). The phosphogluconate pathway also became more prominent in denser cultures. However, population *per se*, rather than cell growth rate, appeared to be responsible for changes in the pattern of carbon flow. The rate of glycogen synthesis/mg protein decreased at higher densities in normal cells. RSV-transformed cells were also affected by population density, but to a lesser degree than normal cells. Regardless of population density, however, the amount of lactate produced and the lactate: CO_2 ratio were always higher in transformed cultures than in normal cultures.

4559 IMMUNODEPRESSIVE EFFECT OF RAUSCHER LEUKEMIA VIRUS ON ANTINUCLEAR ANTIBODY FORMATION IN NEW ZEALAND BLACK MICE. (E.) Siegel, B. V. (U. Oregon Med. Sch., Portland), M. Brown and J. I. Morton. *J Nat Cancer Inst* 48(1):159-163, 1972.

Five-hundredths ml of 10^{-1} , 10^{-2} or 10^{-3} dilution of a second NZB mouse passage of Rauscher leukemia virus (RLV) were inoculated i.p. into baby NZB mice; the influence of RLV infection on anti-nuclear antibody (ANA) development in fresh plasma of infected mice was observed using indirect immunofluorescence. Inoculation with a 10^{-2} dilution of RLV at five days of age depressed total positive ANA reactions to 50-80% of those of controls. The incidence of strongly positive ANA responses in RLV-infected mice generally remained under 50% of that seen in controls. Of 12 virus-inoculated mice surviving 30 days postinoculation, 11 showed leukemic development, peripheral blood smears appearing erythroleukemic in these mice. Virus-infected mice which survived eventually developed ANA responses comparable to, but not exceeding, those of controls. In another experiment, the effect of virus dose was examined in connection with RLV depression of ANA response. Mice received injections of 10^{-1} (high dose) or 10^{-3} (low dose) RLV, while controls received a 10^{-1} concentration of normal NZB spleen extract. Fifty-nine percent of controls showed strong ANA responses during the first month of life, in contrast to 28 and 27%, resp., of mice given low and high doses of RLV. In related experiments, 1.5- and 5-month-old NZB mice showing strongly positive ANA responses were tested for ANA before and at intervals after RLV infection. No diminution in persistence of strong immunofluorescence reactivity was seen in 22 days postinjection. Inoculation of BALB/c and C57BL/6 mice, all negative for ANA, with a 10^{-1} dose of RLV did not cause conversion to positive ANA reactivity.

4560 ACUTE LYMPHOBLASTIC LEUKEMIA: VIRUS-LIKE PARTICLES IN LYMPHATIC CELL INCLUSIONS FROM BONE MARROW AND PERIPHERAL BLOOD. (E.) Sun, C. N. (V. A. Hosp., Little Rock, Ark.), G. E. Byrne and H. Pinkerton. *Exp Pathol (Jena)* 6(1):72-79, 1972.

Intracellular virus-like particles in preparations made directly from leukemic bone marrow are reported. Light and electron microscopic observations of bone marrow obtained from a five-year old girl with acute lymphoblastic leukemia showed abnormal inclusions, 0.5-2 microns in diameter, in the lymphoblasts and mature lymphocytes during routine examination of the first bone marrow aspirate. The number of inclusions varied from two to twelve per cell. They were PAS-positive, and negative with Feulgen, Sudan Black B, Oil Red O and peroxidase methods. Similar inclusions were noted in the lymphocytes seen in the peripheral smears. Electron microscopy (EM) of the bone marrow was performed on the preleukemic phase and at intervals of one, four and twelve weeks after the onset of the leukemic phase. Tissue cultures were started from two of the aspirates and cultures for mycoplasma were negative. Ovoid inclusions corresponding to those observed by light microscopy were noted in the EM studies. Often they were composed of a single limiting membrane, enclosing a dense population of "doughnut type" virus-like particles approximately 400 Å in diameter. In many of the inclusions whorled membranes were present. The morphology of these virus-like particles is similar to the "immature" virus particles observed in murine leukemia, and to virus-like bodies reported in some human lymphomas.

- 4561 THE ROLE OF EPITHELIAL RETICULAR CELLS OF THE THYMUS IN GROSS VIRUS-INDUCED LEUKEMOGENESIS IN THE RAT. (It.) Cali, A. (Inst. Anat. Path. Histol. U. Naples, Italy), R. Vecchione, L. Coscia-Porrazzi and L. Palombini. *Tumori* 57(4):237-246, 1971.

Thymic tissue obtained from 7-10 day-old W/Fu rats was inoculated i.m. after 25 days of culture in the thigh of 40-50 day-old male W/Fu rats which had been thymectomized at birth and inoculated with Gross virus at 3-4 days-of-age. Each rat received a graft (interior part of thigh) containing 2×10^4 cells obtained from a pool of 12 thymuses. The rats were then divided into two groups: 11 rats received Gross virus inoculum in addition to the thymic graft and six rats received no virus and served as controls. Two of the six control rats developed normal thymic tissue islets at the grafting site 4 to 5 months after inoculation, whereas five of the 11 virus-treated rats developed lymphoma at the thymic tissue inoculation site 6 to 8 months after treatment. Inoculation of acellular filtrate of this neoplastic tissue to other rats produced lymphoma indicating that this fluid included Gross virus. The long latency period in the development of lymphoma under the experimental conditions suggests that development of neoplasia is strictly dependent on a preceding restoration of morphologically normal thymus.

- 4562 THE TRANSFORMATION OF BHK 21 HAMSTER CELLS BY SIMIAN VIRUS 40. Wiblin, C. N. (Imp. Cancer Res. Fund, London, England) and I. A.

MacPherson. *Int J Cancer* 10(1):296-309, 1972.

Cells of the C13 clone of baby hamster kidney 21/13 (BHK 21/13) cells were exposed to SV40 at multiplicities of infection ranging from 10^0 - 10^4 plaque forming U/cell. Judging by the efficiency of plating in culture and by SV40 T antigen production, C13 cells were refractory to SV40 transformation and infection. When African green monkey kidney (BS-C-1) cells were infected with SV40 and fused with C13 cells, C13 cells were transformed. Typical SV40 cytopathic effects appeared, colony formation in the cells increased 50-fold over that seen in C13 cells not exposed to SV40-infected BS-C-1 cells, and SV40 T antigen was detected. One transformed C13 alone (C13/SV) was selected for further study. C13/SV cells showed several of the properties of BHK 21 cells transformed by viruses other than SV40. After 350 generations in culture, C13/SV cells induced metastasizing tumors in hamsters; cell lines derived from these metastases were designated C13/SV-M. Metastases of C13/SV-induced tumors were apparently the result of dissemination of the cells rather than of release of infectious SV40. C13/SV-M and C13/Sv cells had similar growth properties *in vitro*. C13/SV-M cells showed properties associated with similar growth properties *in vitro*. C13/SV-M cells showed properties associated with surface alterations in transformed cells. SV40 transplantation antigen may have been masked or absent in C13/SV-M cells.

- 4563 THE RELATIONSHIP BETWEEN THE SOLUBLE ANTIGENS AND THE VIRION OF ADENOVIRUS TYPE 3. VI. FURTHER CHARACTERIZATION OF ANTIGENIC SITES AVAILABLE AT THE SURFACE OF VIRIONS. (E.) Norrby, E. (Karolinska Inst. Sch. Med., Stockholm, Sweden) and G. Wadell. *Virology* 48(3):757-765, 1972.

Adenovirus type 3 was investigated in absorption experiments in which adenovirus 3 rabbit hyperimmune sera against soluble virus components and virions were exhaustively absorbed in the presence of sheep anti-rabbit serum. After absorption with adenovirus 3 antigens, antisera were reacted with adenovirus 3 virions in hemagglutinin-inhibition (HI) tests. These tests demonstrated the presence of antigenic sites at the surface of virions of adenovirus 3 which were not carried by spontaneously occurring soluble 3 components. When antibodies against adenovirus 3 vertex capsomers (represented by an antipenton serum absorbed with purified fibers) or against adenovirus 3 fibers were tested for neutralization of virus activity, efficient neutralization occurred only when both kinds of antibodies (antipenton and antidodecon) were present in reactions, or when anti-rabbit serum was added. Cross reactions between surface antigens of eight adenovirus types (3, 4, 11, 16, 9, 15, 2 and 6) representing all of Rosen's subgroups were investigated in HI tests with purified virions and soluble hemagglutinin in the presence of rabbit hyperimmune sera against soluble components and virions. Cross reactions were found only at low serum dilutions; they occurred predominantly among subgroup members, though some inter-

group reactions were seen. The reactions were due to vertex capsomer-associated subgroup-specific antigen(s). One antiserum against adenovirus type 11 dodecons displayed some neutralization of type 3 virions in the presence of anti-rabbit serum.

- 4564 STUDIES ON TYPE-H VIRUS-LIKE PARTICLES IN HAMSTER: THEIR ROLE IN ONCOGENESIS. (E.) Cesarini, J. P. (Temple U. Hlth. Sci. Ctr., Philadelphia, Pa.) and C. De Micco. *Int J Cancer* 10:174-185, 1972.

Cells from continuous hamster lines, transformed hamster cell clones, transplantable hamster tumor cell lines and primary hamster tumor cell cultures were examined under the electron microscope for the H virus-like particle (H VLP). H VLP was absent in normal hamster tissues and hamster embryos. Primary virus-induced hamster tumors and transplanted tumors were also free of H VLP in all cases but one. H VLP was found in cell lines obtained from an SV40-induced and in cell lines from the BHK 21/13 line, a line of cells transformed by Rous sarcoma virus (RSV) and by polyoma virus. H VLP were seen in association with morphologically different A-type virus-like particles in a BHK 21/13 clone transformed by RSV and then by UV-irradiated polyoma. H VLP was present in swollen cisternae of the rough endoplasmic reticulum but never in cell nuclei.

- 4565 VARIATIONS IN SARCOMA AND LEUKEMIA VIRUS ACTIVITY IN SOMATIC CELL HYBRIDS. (E.) Long, C. (Flow Labs., Inc., Rockville, Md.), G. Gelloff and R. V. Gilden. *Int J Cancer* 10(2):310-319, 1972.

Eight hybrid clones were grown from the fusion of two parental lines: a 3T6 mouse embryo line deficient in hypoxanthine-guanine phosphoribosyl transferase (HGPRT), resistant to 6-thioguanine, and infected with Rauscher leukemia virus (RLV); and a hamster cell line lacking thymidine kinase and carrying defective murine sarcoma virus (MSV) genome. The mouse parent line (TG-8) shed LV and the MSV genome was rescued from the hamster parent line (HT-1) by co-cultivation with an LV-shedding mouse line. The hybrid clones differed morphologically from both parents, being more elongated and refractile. All clones were positive for MuLV group specific (gs) antigen and all lacked hamster leukemia virus gs antigen. Five clones produced equal amounts of sarcoma and leukemia virus; however, two clones produced 100-fold excesses of virus. An eighth clone, which was morphologically like the TG-8 parent, produced leukemia virus but not sarcoma virus. Sarcoma virus could not be rescued from this clone by fusion with RLV-shedding mouse cells. All clones had HGPRT adenosine kinase of hamster origin. Six clones also possessed adenosine kinase of murine origin.

- 4566 MATURATION OF INFECTIOUS SIMIAN VIRUS 40 IN THE PRESENCE OF ETHIDIUM BROMIDE. (E.) Kletmann, W. (Wistar Inst., Philadelphia, Pa.), K. Kato and H. Koprowski. *J Gen Virol* 15:35-44, 1972.

DNA synthesis in SV40-infected and uninfected African green monkey cells was measured in cultures containing or lacking ethidium bromide (EB). Virus DNA synthesis and mitochondrial DNA (M-DNA) synthesis were observed by submitting extracted virus and M-DNA to isopycnic CsCl-EB gradient centrifugation to separate the closed-circular (component I) and nicked-circular (component II) portions of virus and M-DNA. EB increased total DNA synthesis and nuclear DNA synthesis in uninfected cells. In uninfected cells, 4 µg/ml EB removed component I M-DNA from the CsCl-EB gradients. In SV40-infected cells, neither 4 nor 8 µg/ml EB affected nuclear DNA synthesis. Component II M-DNA was reduced by 4 mg/ml EB. Production of SV40 progeny virus was not affected by EB, nor was the infectivity of SV40.

- 4567 COMPARED ACTION OF A POLYOMA-VIRUS-SPECIFIC INHIBITOR ON THE FORMATION OF POLYOMA CAPSID ANTIGEN AND OF POLYOMA TUMOR ANTIGEN. (E.) Meyer, G. (C.R.A.C.M., Marseille, France), R. Cramer and H. Yoshikura. *Int J Cancer* 10:128-133, 1972.

A virus-specific inhibitor protein factor was extracted from polyoma virus-infected baby hamster kidney cells by sonication and centrifugation. The inhibitor was added to mouse embryo cells one hr after they were infected with polyoma virus. Immunofluorescence was used to test for the formation of polyoma virus capsid antigen and tumor (T) antigen. By 48 hr after infection, capsid antigen appearance was reduced by more than 90% in inhibitor-treated infected cells as compared with infected cells not treated with inhibitor. The inhibitor did not affect the kinetics of polyoma T antigen appearance in infected cells.

- 4568 ULTRASTRUCTURAL LOCALIZATION OF CONCANAVALIN A RECEPTORS IN NORMAL AND SV40-TRANSFORMED HAMSTER AND RAT CELLS. (E.) Bretton, R. (Inst. Sci. Res. Cancer, Villejuif, France), R. Wicker and W. Bernhard. *Int J Cancer* 10(2):397-410, 1972.

Normal and SV40-transformed hamster cells were cultured and treated with concanavalin A (Con A) and horseradish peroxidase, and the distribution of Con A receptor sites on cell surfaces was observed by examining peroxidase reactions under the electron microscope. All normal and transformed cells treated with Con A-peroxidase showed strong surface reactions. Normal hamster cells showed a continuous layer of electron-dense material indicating that the Con A receptor areas were evenly distributed over the cell coat. SV40-transformed cells showed a more patchy and uneven distribution of Con A

receptor sites. The distinction between evenly and unevenly distributed Con A receptor sites on the cell surfaces was detectable even after 108-112 passages of normal or transformed cells. No differences between the distribution of Con A receptor sites could be discerned between normal or SV40-transformed rat cells.

- 4569 TYPE C VIRUSES IN THE PANCREAS OF NORMAL C57BL MICE. (E.) Della Torre, G. (Natl. Inst. Study Cure Tumors, Milan, Italy) and G. Della Porta. *Cancer Res* 32:1595-1597, 1972.

Pancreases and thymuses from normal C57BL mice, normal C3Hf mice, and normal AKR mice were examined under the electron microscope for the presence of type C viruses. C-type virus particles were found in 20 of 22 pancreases from C57BL mice aged more than 3 wk; few particles were seen in younger C57BL mice. In the older mice, the particles were seen budding from membranes of intracytoplasmic vacuoles and cisternae of endoplasmic reticulum in pancreatic acinar cells. Thymuses of C57BL mice, both newborn and >3 wk old, also harbored C-type particles, but in smaller numbers than the pancreases. No type C particles were found in the pancreases of C3Hf or AKR mice. In the thymus of these strains, type C particle distribution was essentially similar to that in C57BL mice.

- 4570 POLYPEPTIDES OF AVIAN RNA TUMOR VIRUSES. IV. COMPONENTS OF THE VIRAL ENVELOPE. (E.) Bolognesi, D. P. (Max-Planck Inst., Tübingen, Germany), H. Bauer, H. Gelderblom and G. Hüper. *Virology* 47:551-566, 1972.

Avian myeloblastosis virus (AMV), recovered from myeloblasts from the blood of leukemic chickens, was concentrated by ultracentrifugation and fractionated by sucrose density centrifugation. The virus-containing band was then centrifuged on a sucrose gradient. Viruses were split by sedimentation through NP40 and DTT and further density gradient centrifugation. The fraction banding at 1.19 g/cm³ consisted mainly of rosette-like structures (300 Å in diameter) having the dimensions of projections on the outer surface of the virus. The rosettes represented 60% of viral carbohydrate and 7% of viral protein. When rosettes were treated with SDS and DTT and electrophoresed on acrylamide gels, two major proteins (viral glycoproteins) appeared with molecular wts of 37,000 daltons (the GI protein) and 115,000 daltons (GII). GII could be isolated without SDS treatment and resembled the knob-like portion of the complete rosette. GI and GII specifically absorbed neutralizing sera and precipitated with these sera in immunodiffusion tests. In other serum absorption tests, rosettes appeared to possess material which specifically absorbs a neutralizing antibody against a virus from subgroup B. This suggested that biologically acute Ve antigen was present in rosettes. When rosettes were tested in gel

diffusion using nonneutralizing rabbit antisera, a precipitation line was seen. The corresponding antigen was apparently not identical with any of the four complement-fixing antigens of AMV. The rosettes possessed at least two antigenic specificities, one residing in GI, one in GII. It was concluded that the surface projections of AMV, associated with rosette structures, represented the viral type-specific antigens.

- 4571 RIBONUCLEASE-SENSITIVE ENDOGENOUS DNA POLYMERASE ACTIVITY AND DNA-DIRECTED POLYMERASE IN HUMAN TISSUE CULTURE CELL LINES. (E.) Srivastava, B. I. S. (Roswell Park Mem. Inst., Buffalo, N.Y.) and J. Minowada. *Cancer Res* 32(11):2481-2486, 1972.

The 37,000 X g supernatant ("soluble") activity, the chromatin-associated DNA-directed DNA polymerase activity, and the soluble RNase-sensitive endogenous DNA polymerase activity were examined in two fibroblast cell lines (WI-38 and WI-38VA13), in 13 lymphoid cell lines originated from normal persons or from acute lymphocytic leukemia, acute myelocytic leukemia, Burkitt lymphoma, or multiple myeloma patients, and also in cells obtained directly from patients with acute lymphocytic leukemia, acute myelocytic leukemia, multiple myeloma, or lymphosarcoma. RNase-sensitive endogenous DNA polymerase activity, which was 1/1000 to 1/10 of DNA-directed soluble DNA polymerase activity, was lowest in WI-38 cells and highest in lymphoblasts from acute lymphocytic leukemia patients. The soluble and chromatin-associated DNA-directed DNA polymerase activity of WI-38V13 cells, compared to that of WI-38 cells, and the activity of acute myelocytic leukemia, Burkitt lymphoma, and multiple myeloma cells, compared to that of normal cells, were two to ten times higher; in contrast, the activity of cells of acute lymphocytic leukemia or lymphosarcoma origin was one-third to one-half that of normal cells.

- 4572 ONCOGENICITY OF FELINE FIBROSARCOMA VIRUSES IN MARMOSET MONKEYS: PATHOLOGIC, VIROLOGIC, AND IMMUNOLOGIC FINDINGS. (E.) Wolfe, L. G. (Rush-Presbyterian-St. Luke's Med. Ctr., Chicago, Ill.), R. D. Smith, J. Hoekstra, B. Marczyńska, R. K. Smith, R. McDonald, R. L. Northrop and F. Deinhardt. *J Nat Cancer Inst* 49(2):519-539, 1972.

Seventy-five marmosets were injected i.p. and/or i.m. with cell-free concentrates of cat tumors induced by Snyder-Thelen or Gardner-Arnstein feline sarcoma virus (ST- and GA-FeSV). A total of 53 intraabdominal or injection-site sarcomas developed in 19 marmosets inoculated neonatally or up to eight yr of age. ST-FeSV induced undifferentiated sarcomas while GA-FeSV induced well-differentiated fibrosarcomas. Pulmonary and regional lymph node metastases were seen in 20% of inoculated marmosets. Ten marmoset-to-marmoset passages, with tumors induced by either virus, were accomplished; all marmosets inoculated with intact tumor cells developed tumors, usually composed

of recipients' cells. Primary sarcomas showed group-specific (gs) antigen but lacked C-type virus particles, while cell lines established *in vitro* from these tumors and transplanted tumors contained infectious virions. One of 14 cell-free extracts from marmoset tumors induced foci in cat embryo cells *in vitro*. Virus produced by cultured marmoset tumors was oncogenic in marmosets and in cats. Gs antibodies were present in sera of 17 of 50 tumor-bearing marmosets.

- 4573 EFFECT OF MAMMARY TUMOR VIRUS INFECTION ON *IN VIVO* OXIDATION OF GLUCOSE-1-¹⁴C AND GLUCOSE-6-¹⁴C IN C3H MICE. (E.) Burki, H. R. (Northwestern U. Med. Sch., Chicago, Ill.) and G. T. Okita. *Cancer Res* 31(12):1955-1961, 1971.

A two-part study was conducted to compare the rate of *in vivo* oxidation of glucose-1-¹⁴C and glucose-6-¹⁴C in C3H tumor-free and C3Hf (factor-free) virgin female mice of different ages, and to determine the effect of the presence of small foci of mammary tumor tissue on the *in vivo* metabolism of glucose-¹⁴C. Although no differences were observed between young mice of the two strains, C3H virgins older than 40 wk oxidized glucose-6-¹⁴C to ¹⁴CO₂ at a faster rate than C3Hf virgins of the same age. In addition, C3H mice older than 40 wk had significantly lower body wt than the C3Hf controls. No age-dependent interstrain differences in the rate of glucose-1-¹⁴C oxidation were observed. Injection s.c. of an homogenate of a spontaneous mammary tumor which arose in a C3H mouse resulted in a significant reduction in body wt and an increase in glucose-6-¹⁴C oxidation in C3Hf but not C3H virgins. The tumor nodules grew progressively in the C3Hf but not in the C3H mice. These results imply that degradation of glucose by the glycolysis-Krebs cycle pathway, but not by the pentose shunt, was increased in aging and in tumor-bearing C3H virgin mice.

- 4574 LEUKEMIA VIRUS-INDUCED IMMUNOSUPPRESSION. VIII. RAPID DEPRESSION OF *IN VITRO* LEUCOCYTE MIGRATION AFTER INFECTION OF MICE WITH FRIEND LEUKEMIA VIRUS. (E.) Friedman, H. (Einstein Med. Ctr., Philadelphia, Pa.) and W. S. Ceglowski. *J Immunol* 107(6):1673-1681, 1971.

BALB/c mice were inoculated i.p. with a 10⁻¹ dilution preparation of Friend leukemia virus (FLV); at various times after inoculation, mice were killed and spleen, lymph node, thymus and bone marrow cells were placed in capillary tubes to test their migratory capacities. Excellent migration was seen with spleen cells of uninfected mice, while migration of spleen cells of infected mice was markedly inhibited by three to five days postinoculation. Normal spleen cells showed areas of migration of 16.3 ± 3.9 mm², while spleen cells from FLV-infected mice showed areas of 10.1 ± 2.5 mm² on day three and 4.2 ± 1.1 to <2.0 mm² six to 20 days postinfection. No inhibition of migration was seen in spleen cells of FLV-infected mice one

day postinfection. Spleen cell migration inhibition was less pronounced in mice infected with FLV at dilutions of 10⁻² or 10⁻³. Lymph node and marrow cells migration was not as affected by FLV infection as was spleen cells; migration of these cells was not inhibited until two or three wk postinfection. Thymus cells showed no migration inhibition until four wk postinfection. No migration-inhibiting factor was detected in culture supernatants of spleen cells from infected mice sensitized with allogeneic mouse skin grafts or tubercle bacilli and challenged *in vitro* with the appropriate antigen. Similar cultures from uninfected mice released a lymphoid cell migration-inhibiting factor.

- 4575 SENSITIVITY OF EPSTEIN-BARR VIRUS (EBV) PRODUCER AND NON-PRODUCER HUMAN LYMPHOBLASTOID LINES TO SUPERINFECTION WITH EB-VIRUS. (E.) Klein, G. (Karolinska Inst., Stockholm, Sweden), L. Dombos and B. Gothoskar. *Int J Cancer* 10:44-57, 1972.

Twenty-nine human lymphoblastoid cell lines, including lines from Burkitt's lymphoma, nasopharyngeal carcinoma, infectious mononucleosis and normal blood, were exposed to Epstein-Barr virus (EBV) and virus absorption by cells and the production of early antigen (EA) by exposed cells were observed. EBV absorption was assessed by counting the numbers of direct membrane fluorescence-positive cells immediately after infection and by the direct radioimmune membrane labeling method. Eleven of the lymphoblastoid cell lines were "nonproducers", (i.e., produced little or no EA or EBV viral capsid antigen (VCA) in separate tests). Virus absorption and subsequent appearance of EA-positive cells were concordant in mice of the 11 nonproducer lines. Five nonproducer lines absorbed the most EBV (71-62% of virus-exposed cells positive for absorption); four of these five lines developed significant percentages of EA-positive cells after EBV infection. Four nonproducer lines which absorbed EBV remained EA negative. Eighteen cell lines were "producers" (i.e., produced much EA and VCA in separate tests). Four of these lines showed increased EA production and absorbed EBV readily. Of the 14 producer lines showing little or no increase in EA production, these five showed relatively good EBV absorption. One IgE-producing human myeloma cell line showed neither EBV absorption nor EA development.

- 4576 INHERITANCE OF SUSCEPTIBILITY TO FRIEND MOUSE LEUKEMIA VIRUS. VIII. EFFECT OF A SINGLE GENETIC LOCUS ON THE PATHOGENESIS OF THE LEUKEMIA. (E.) Okada, T. (Inst. Med. Sci., Tokyo, Japan), H. Sugano and K. Takizawa. *Int J Cancer* 10(2):382-390, 1972.

The effect of the Fv locus, which controls the early response to Friend leukemia virus (FLV), on the pathogenesis of FLV-induced leukemia was studied in two pairs of mouse strains (DDD and C57BL/6) which are congenic except for this locus. Rapid spleen enlargement and spleen focus formation, which are

characteristic of FLV infection, were seen in young mice with the Fv^S/Fv^S genotype (DDD and C57BL/6-Fv^S) but not in young mice with the Fv^r/Fv^r genotype (DDD-Fv^r and C57BL/6) following i.p. injection of virus. When the infected Fv^r/Fv^r mice were observed for 150 days, all of the DDD-Fv^r mice developed splenomegaly whereas none of the C57BL/6 mice did. Histologic observation of the DDD-Fv^r splenomegalic mice revealed erythroblastic ("Friend cells"), lymphatic or granulocytic leukemia, or myeloproliferative disorder with a prominent megakaryocytic proliferation. These results indicate that FLV is able to induce various types of leukemias in mice and that the early responses can be completely abrogated in mice with an Fv^r/Fv^r genotype. Genetic factors other than the Fv locus may be involved in the late-occurring FLV-induced leukemias.

- 4577 MAMMARY GLAND TUMORS IN SUBSTRAINS C57BL/M AND C57BL/He MICE. (E.) Heston, W. E. (Natl. Cancer Inst., Bethesda, Md.), G. Vlahakis and G. H. Smith. *J Nat Cancer Inst* 49(3):805-812, 1972.

A few spontaneous mammary tumors were observed in breeding female mice of substrains C57BL/M and C57BL/He; the incidence in C57BL/M was somewhat higher than in C57BL/He. This correlates with former observations that whereas C57BL/He is genetically resistant to the mammary tumor virus (MTV), C57BL/M is much more susceptible. Mammary tumors were induced with hypophyseal isografts without the introduction of MTV in both substrains and, as further correlation with their genetic susceptibility, the incidence in the C57BL/M females was somewhat higher than in the C57BL/He females. All the hypophyseal isograft-stimulated mammary tumors were adenocarcinomas. No morphologic evidence was obtained for the presence of "derepressed" MTV in these C57BL mammary tumors induced by hypophyseal isografts. In the primary spontaneous tumors extracellular particles and budding forms were observed. Some of these were classified as type-C particles but others were difficult to interpret. The possibility that some of these particles were type B remains open. In line with the genetic resistance and susceptibility of the two substrains, these extracellular particles were seen only in the spontaneous tumors of the C57BL/M substrain. The spontaneous tumors were intertransplantable between the two substrains, though the substrains have been separated since before 1936.

4611 ANTIGENIC RELATIONSHIP BETWEEN THE HERPES-VIRUS OF INFECTIOUS BOVINE RHINOTRACHEITIS, MAREK'S DISEASE, AND BURKITT'S LYMPHOMA. (E.)

Evans, D. L. (M.D. Anderson Hosp. Tumor Inst., Houston, Texas), J. W. Barnett, J. M. Bowen and L. Dmochowski. *J Virol* 10(2):277-287, 1972.

Common herpesvirus (HV) antigens in infectious bovine rhinotracheitis (IBR), Marek's disease (MDV), and Burkitt's lymphoma (EBV) were found. Immunodiffusion tests in 0.7% agarose demonstrated a line of identity with the HV preparations by using specific antisera prepared against IBR, MDV, and EBV. These common antigens were found to consist of multiple components: i.e., at least two MDV antigens were identical to IBR and EBV components when subjected to immunoelectrophoresis in 0.7% agarose. Indirect immunofluorescence testing of EBV strain P₃HR-1 and IBR-infected embryonic bovine kidney cells, when antisera prepared against partially purified IBR, MDV, and EBV antigens, revealed identical activity of the three antisera as demonstrated by brilliant nuclear fluorescence in P₃HR-1 cells and evenly distributed cytoplasmic activity in 18-hr IBR-infected bovine kidney cell cultures. Initial physical-chemical studies of the partially purified antigens were carried out by differential centrifugation cycles (6,000, 25,000 and 100,000 X g), rate zonal centrifugation in 5 to 20% sucrose density gradients, and analysis by disc electrophoresis in 5 and 7% polyacrylamide gels. These studies revealed similar molecular weight (>1,000,000) and size characteristics and similar electrophoretic mobilities among the three partially purified HV antigens.

4612 COUNTERACTION OF THE BLOCKING OF CELL-MEDIATED TUMOR IMMUNITY BY INOCULATION OF UNBLOCKING SERA AND SPLENECTOMY: IMMUNOTHERAPEUTIC EFFECTS ON PRIMARY POLYOMA TUMORS IN RATS. (E.) Bansal, S. C. (Fred Hutchinson Cancer Res. Ctr., Seattle, Wash.) and H. O. Sjögren. *Int J Cancer* 9(3):490-509, 1972.

Polyoma virus-induced sarcoma cells were inoculated s.c. into rats two to eight days before injection of an "unblocking" serum prepared by i.p. inoculation of rats with *Bacillus Calmette-Guérin* and later challenge with polyoma tumor cells. The effect of unblocking serum on the antibody-associated blocking activity of sera from tumor-bearing rats was studied by observing the cytotoxicity of lymphocytes for tumor cells; blocking serum from tumor-bearing rats ordinarily depresses the cytotoxic response of circulating lymphocytes against tumor cells. Four of five rats given polyoma tumor cells and unblocking sera failed to develop detectable levels of serum blocking; tumor isografts in these rats grew progressively for 2 wk, then regressed completely. In a second experiment, kidney sarcomas were induced by polyoma virus inoculation; tumor-bearing rats were splenectomized and then treated with unblocking serum. Blocking activity of sera from tumor-bearing splenectomized rats decreased or disappeared as a result of treatment with unblocking sera. In related experiments, splenectomized, kidney polyoma tumor-bearing rats

were injected with unblocking serum or with normal rat serum. Serum blocking activity decreased in rats given unblocking serum but not in rats given normal serum. Sera of rats given no treatment or treated with normal sera had no cytotoxicity for polyoma tumor cells, but serum from rats given unblocking serum did show cytotoxicity. Kidney tumors in rats not given unblocking serum grew rapidly while tumor growth rate was considerably slower in five of eight rats given unblocking serum. In addition, the survival time of nine of 11 rats given unblocking serum was significantly prolonged relative to the survival time in rats not given unblocking serum.

4613 DIFFERENCES IN THE BINDING OF FLUORESCENT CONCAVALIN A TO THE SURFACE MEMBRANE OF NORMAL AND TRANSFORMED CELLS. (E.) Shoham J. (Weizmann Inst. Sci., Rehovot, Israel) and L. Sachs. *Proc Nat Acad Sci USA* 69(9):2479-2482, 1972.

The binding of fluorescein-conjugated Concanavalin A to the cell surface has been studied in normal and transformed cells in interphase and mitosis. Binding to the cell surface was in the form of an incomplete ring of fluorescence, and the binding was inhibited by α -methyl-D-mannopyranoside. All the cells were fluorescent when treated with 25-250 μ g/ml of fluorescent Concanavalin A. With 10 μ g, the cells were all fluorescent after 30 min of binding, but after 0.5-5 min with 10 μ g or 30 min with 1 or 2.5 μ g, transformed interphase cells showed a higher percentage of cells with surface fluorescence than did normal interphase cells. Trypsinized normal and transformed interphase cells showed the same fluorescence. Binding with 2.5 μ g at 4 C instead of at 24 C, gave a higher percentage of fluorescent cells with trypsinized than with untrypsinized transformed cells. Mitotic normal cells were similar to transformed interphase cells, whereas mitotic transformed cells were intermediate between normal and transformed interphase cells. The results indicate that the use of low concentrations of fluorescent Concanavalin A can show differences in surface fluorescence between normal and transformed, interphase and mitotic, and trypsinized and untrypsinized cells. It is suggested that the observed differences in fluorescence can be explained by differences in affinity of the lectin binding sites and/or differences in the clustering of sites.

4614 MEMBRANE IMMUNOFLOURESCENCE STUDIES ON CELLS PRODUCING RAT C-TYPE VIRUS PARTICLES. (E.) Pearson, G. (Natl. Cancer Inst., Bethesda, Md.), T. Orr, L. Redmon and V. Bergs. *Int J Cancer* 10:14-19, 1972.

Cells of the WF-1 rat line, a spontaneously transformed line which originated from embryos of W/Fu inbred rats and produced large amounts of rat C-type virus, were treated with antisera prepared by inoculating W/Fu rats with WF-1 cells. Membrane immunofluorescence was used to detect anti-WF-1

antibodies. Antisera gave positive reactions with 20-35% of WF-1 cells but did not react with normal embryonic W/Fu fibroblasts. Anti-WF-1 sera also reacted with R-35 and RMTL-8 cells, virus producing cell lines derived from rat mammary tumors. Anti-WF-1 sera did not react with nonvirus producing cell lines, and absorption of pooled reactive sera with normal W/Fu cells failed to remove antibodies against WF-1 cells.

- 4615 CELL-SPECIFIC ANTIGENS AND IMMUNOGLOBULIN SYNTHESIS OF MURINE MYELOMA CELLS AND THEIR VARIANTS. (E.) Hyman, R. (Salk Inst. Biol. Stud. San Diego, Calif.), P. Ralph and S. Sarkar. *J Nat Cancer Inst* 48 (1):173-184, 1972.

Immunoglobulin synthesis and secretion, surface antigens, and murine leukemia virus (MuLV) group-specific (gs) antigens were studied in seven myeloma tissue cultures from BALB/c (six lines) and C3H (one line) mouse tumors, and in nine variants of these myeloma cell lines. The amount of IgG secreted by myeloma cells relative to total protein synthesis was similar in all seven lines. For myelomas secreting IgG, the ratio of radioactivity in secreted L and H chain IgG was approximately 2; in two myelomas secreting IgA, an excess of H chains was secreted. Plasma cell surface antigens and histocompatibility antigen $H-2^d$ were present in BALB/c myelomas; $H-2^k$ was seen in the C3H myeloma line. Gross leukemia virus antigens were determined in myeloma lines with both mouse and rat anti-Gross virus antisera. All but one myeloma line showed MuLV gs antigen. Among myeloma cell line variants, those which did not synthesize immunoglobulins showed greatly reduced amounts of histocompatibility antigens and Gross virus antigens; variants not synthesizing immunoglobulins also lacked detectable plasma cell-specific antigens.

- 4616 CELLULAR IMMUNOABSORBENTS IN TRANSPLANTATION IMMUNITY: SPECIFIC *IN VITRO* DELETION AND RECOVERY OF MOUSE LYMPHOID CELLS SENSITIZED AGAINST ALLOGENEIC TUMORS. (E.) Berke, G. (Harvard Med. Sch., Boston, Mass.) and R. H. Levey. *J Exp Med* 135(4):972-984, 1972.

Mice of various strains were immunized against allogeneic tumors by i.p. injection of tumor cells; the tumors were the spindle-shaped sarcoma (SaI) of the A/J mouse, the EL4 leukosis of the C57BL/6 mouse, and the P815 mastocytoma of the DBA/2 mouse. Spleen cells were collected from innune mice and the lysis of tumor target cells *in vitro* by spleen cells was observed by measuring ^{51}Cr release from labeled target tumor cells. Degree of lysis of tumor cells by immune spleen cells was specific for each tumor; when labeled tumor cells were incubated with normal spleen cells, lysis was not increased over that of tumor cells not mixed with any spleen cells. The lytic capacity of sensitized spleen cells previously incubated on mouse embryo fibroblast monolayers and then removed was studied. BALB/c anti-EL4 spleen cells

incubated on C57BL/6 embryo monolayers (syngeneic with EL4) were only slightly cytotoxic to EL4 tumor cells; BALB/c anti-EL4 spleen cells not incubated with mouse monolayer were fully cytotoxic to the tumor cells. BALB/c anti-EL4 spleen cells incubated with fibroblasts from other mouse strains showed unimpaired cytotoxicity for EL4 cells. Similar results were obtained with C57BL/6 anti-SaI spleen cells and C57BL/6 anti-P815 spleen cells. Upon incubation of cytotoxic spleen cells with specific mouse embryo fibroblasts, specifically sensitized cytotoxic cells were selectively absorbed onto monolayers and remained adherent after other spleen cells were removed. Adherent cytotoxic cells could be removed from monolayers by trypsinization and separation on discontinuous albumin gradient. These recovered cells were cytolytic for tumor cells. Sensitized spleen cells neutralized tumor growth *in vivo* when injected into mice; tumor growth-inhibiting capacity of spleen cells was depleted by incubation of spleen cells on mouse embryo fibroblast monolayers. Cytolytic spleen cells recovered from such monolayers retained their ability to inhibit tumor growth *in vivo*.

- 4617 ANTIBODIES PRODUCED BY IMMUNIZATION OF GOATS WITH 40S RIBOSOMAL SUBUNITS FROM NOVIKOFF HEPATOMA ASCITES CELLS. (E.) Busch, R. K. (Baylor Coll. Med., Houston, Texas), W. H. Spohn, Y. Daskal and H. Busch. *Proc Soc Exp Biol Med* 140(3):1030-1033, 1972.

The 40S and 60S ribosomal subunits were separated from the Novikoff ascites hepatoma by sucrose gradient centrifugation; antisera against these subunits were prepared by inoculation of goats. Goat sera from animals inoculated with 40S subunits produced marked agglutination when mixed *in vitro* with Novikoff ascites hepatoma target cells. Antisera to 60S subunits also agglutinated Novikoff target cells. Antisera to 60S subunits agglutinated Walker tumor ascites cells, but antiserum to 40S subunits did not. Both 40S and 60S subunit antisera gave positive immunofluorescence reactions with Novikoff cells. When mixed with Novikoff cells and inoculated i.p. into rats, antisera to 40S subunits delayed tumor growth more than antisera to 60S subunits. However, combined anti-40S and -60S sera suppressed tumor growth more effectively than either antiserum alone.

- 4618 AUTOGENOUS IMMUNITY TO ENDOGENOUS RNA TUMOR VIRUS ANTIGENS IN MICE WITH A LOW NATURAL INCIDENCE OF LYMPHOMA. (E.) Hanna, M. G., Jr. (Oak Ridge Natl. Lab., Tennessee), R. W. Tennant, J. M. Yukas, N. K. Clapp, B. L. Batzing and M. J. Snodgrass. *Cancer Res* 32(10):2226-2234, 1972.

The immune reactivity to endogenous (wild-type) RNA tumor virus-related antigen(s) was evaluated in RF mice, a strain with a low natural incidence of lymphoma. The purposes were to determine whether maintained humoral immunity could be detected and to evaluate the response with respect to the immune-

mediated pathogenesis of glomerulosclerosis and incidence of tumors of lymphatic origin. Measurements of detectable murine leukemia virus antigen in the thymus and spleen were correlated with the development of immune competence, glomerulosclerosis, and the incidence of lymphoid neoplasia. Also, the specificity of the antibody that lodged in the kidney was determined by elution and indirect immunofluorescence with Gross virus-infected cells. A marked decrease in detectable murine leukemia virus antigen in thymus and spleen was found to correlate with development of immunological competence of the spleen as assayed by *de novo* germinal-center formation, antigen localization, and immune elimination from serum, which in turn correlated with occurrence of glomerulosclerosis. The antibody in the kidney was determined to be specific for Gross virus antigen(s). The role of this autogenous immunity may be considered to be beneficial in the RF mouse, as data correlating natural lymphoid neoplasia with severity of immune-complex glomerulosclerosis indicates that an inverse relationship is established in aged animals.

- 4619 CELL-MEDIATED TUMOR IMMUNITY MEASURED *IN VITRO* AND *IN VIVO* WITH SOLUBLE TUMOR-SPECIFIC ANTIGENS. (E.) Meltzer, M. S. (Natl. Cancer Inst., Bethesda, Md.), J. J. Oppenheim, B. H. Littman, E. J. Leonard and H. J. Rapp. *J Nat Cancer Inst* 49(3):727-734, 1972.

Tumor-specific cellular immunity to lines of diethylnitrosamine-induced guinea pig hepatomas was demonstrated *in vitro* by macrophage migration inhibition and lymphocyte transformation, with water-soluble tumor antigens as the eliciting immunogens. Antigens from the ascites form of line-1 and line-10 tumors were extracted with 3 M KCl and partially purified by ammonium sulfate precipitation. Peritoneal exudate cells from strain-2 guinea pigs immune to one or the other of the tumor cell lines were used for the *in vitro* studies; a lymphocyte-rich subpopulation was used for lymphocyte transformation. Cellular responses to the solubilized tumor antigens were tumor line specific and dose dependent in both lymphocyte transformation and macrophage migration inhibition assays.

- 4620 ANTIGENIC CHANGES ON THE SURFACE OF LYMPHOCYTES FROM PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA. (E.) Bentwich, Z. (Hebrew U.-Hadassah Med. Sch., Jerusalem, Israel), D. W. Weiss, D. Sulitzeanu, E. Kedar, G. Izak, I. Cohen and O. Eyal. *Cancer Res* 32:1375-1383, 1972.

Rabbit antisera were prepared against white blood cells (WBC) from blood of patients with chronic lymphocytic leukemia (CLL) and against normal human lymphocytes. The cytotoxicity of these antisera against CLL WBC, normal WBC, lymphocytes from patients with nonleukemia neoplastic or nonneoplastic conditions, and lymphocytes of normal new-

borns was observed. After absorption with normal adult WBC, antisera showed marked cytotoxic activity against all CLL WBC target cells and against some newborn lymphocytes; no activity against the other target cells was seen. Differences in cytotoxic activity of absorbed anti-CLL WBC sera for normal lymphocytes and CLL WBC apparently reflected differences inherent in normal and leukemic cell surfaces rather than absorption of serum proteins onto leukemia cell surfaces.

- 4621 IMMUNE RESPONSE TO GROSS VIRUS-INDUCED LYMPHOMA. III. CHARACTERISTICS OF THE CELLULAR IMMUNE RESPONSE. (E.) de Landazuri, M. O. (Natl. Cancer Inst., Bethesda, Md.) and R. B. Herberman. *J Nat Cancer Inst* 49(1):147-154, 1972.

W/Fu rats were inoculated s.c. with 10^8 cells of a W/Fu rat transplantable, Gross virus-induced lymphoma and studied for the development of cellular immunity. Spleens, regional and distal lymph nodes, thymuses, peripheral blood, bone marrow and peritoneal cells were collected from immunized rats and mixed with ^{51}Cr -labeled lymphoma target cells to investigate cellular cytotoxicity induced in these lymphoid cell populations. Cellular immunity, assayed as lysis of target cells by lymphoid cells, was first detected in regional lymph node cells four days after immunization. Cytotoxicity developed later in peripheral blood lymphocytes, spleen cells and peritoneal cells. Distal lymph nodes, thymus and bone marrow cells showed little or no cytotoxicity. Reactive cells reached peak cytotoxicity levels 6-14 days after immunization; cytotoxicity declined rapidly thereafter. Comparison of the activity of lymphoid cell populations at attacker: target cell ratios from 200:1 to 10:1 showed that blood lymphocytes were the most reactive at high ratios and also the most effective at low ratios. Purification of lymphoid cells increased cytotoxic effects, but the differences in reactivity among different lymphoid cell populations could not be entirely explained by the percent of lymphocytes in preparations. Cytotoxic immune lymphoid cells retained their cytotoxicity after 4000 R of X-irradiation.

- 4622 DETECTION OF HUMAN LEUKAEMIA ASSOCIATED ANTIGENS IN LEUKAEMIC SERUM AND NORMAL EMBRYOS. (E.) Harris, R. (Roy. Infirm., Manchester, England), D. Viza, R. Todd, J. Phillips, R. Sugar, R. F. Jennison, G. Marriott and M. H. Gleeson. *Nature* 233(5321):556-557, 1971.

A double diffusion technique (DD) and crossover electrophoresis (COE) were used to detect leukemia-associated antigens (LAA) in sera from 50 leukemic patients. With a suitably absorbed xenogenic antiserum, FXP prepared against material extracted from acute myeloblastic leukemia cells, circulating LAA were observed in sera from about one-third of the patients. Positive reactions were obtained with 15 of 50 patients' sera tested by the COE technique

and with two of 50 specimens tested by the DD method. Five of six fetal sera were positive by both methods. Negative results were obtained with all 22 sera samples from healthy volunteers. Common oncogenic viruses may be involved in producing LAA, and hitherto unsuspected etiological heterogeneity may exist within the framework of current histological classification. More sensitive techniques and stronger antisera now being investigated may detect a larger number of positive reactions. It is not yet clear to what extent quantitative and qualitative phenomena are involved.

4623 CELLULAR REACTIONS AGAINST BURKITT LYMPHOMA CELLS. II. EFFECTOR CELLS OBTAINED BY ALLOGENEIC STIMULATION IN MIXED LEUKOCYTE CULTURES. (E.) Golub, S. H. (Karolinska Inst., Stockholm, Sweden), J. F. Hewetson, E. A. J. Svedmyr and S. Singh. *Int J Cancer* 10:150-156, 1972.

Peripheral blood leukocytes from healthy humans were stimulated by incubation with Burkitt lymphoma cells or allogeneic human leukocytes; the ratio of healthy leukocytes to stimulator lymphoid cells was 2:1. Cells surviving incubation with stimulator lymphoid cells were tested for effector cell activity. Potential effector cells were incubated with the Burkitt lymphoma cells used for stimulation or with other cells, and colony inhibition (CI) in these incubation mixtures was observed. Optimal effector cell activity against the Burkitt lymphoma cells used to stimulate effector cells was obtained when leukocytes were incubated with stimulator cells for 4-7 days. When effector:target cell ratios were relatively low (e.g., 10:1 as opposed to 100:1) CI activity was largely specific for target cells of the same lines used to stimulate effector cells. When normal leukocytes were stimulated with non-Burkitt lymphoma leukocytes, CI activity of resulting effector cells was strongly restricted to target cells of the same lines used for stimulation. Stimulation with Burkitt lymphoma cells, on the other hand, produced effector cells having CI activity which was cross-reactive with other Burkitt lymphoma cells.

4624 IMMUNOLOGICAL STUDY OF POLYPS OF THE COLON. (E.) Burtin, P. (Inst. Res. Cancer, Villejuif, France), E. Martin, M. C. Sabine and J. von Kleist. *J Nat Cancer Inst* 48(1):25-32, 1972.

Indirect immunofluorescence reactions with rabbit antisera against normal human colonic mucosa, cytoplasmic antigen, plasma membrane antigen and gastrointestinal cancer carcinoembryonic antigen (CEA) were performed against samples of 25 colonic polyps. Some polyps were polyposis- or colon cancer-associated, others were solitary and not associated with cancer. Polyps were classified into three groups according to their degree of differentiation. In immunofluorescence tests, normal cytoplasmic antigen reactions were strongly reduced

or absent in some polyps, but were at nearly normal levels in others. Cytoplasmic antigen fluorescence was reduced mainly in relatively undifferentiated polyps. Membrane fluorescence corresponding to the colonic membrane antigen was decreased or lacking in tested polyps. CEA reactions were seen in all polyps but were stronger in well-differentiated polyps than in undifferentiated polyps. A precipitation reaction was also seen between a monospecific anti-CEA antiserum and the perchloric extract of a pool of benign polyps. CEA was not seen in tests with normal colonic mucosa but was seen in hemorrhoidal mucosa samples and in samples of other noncancerous mucosa.

4625 ABSENCE OF CIRCULATING ANTIBODIES TO CARCINOEMBRYONIC ANTIGEN IN PATIENTS WITH GASTROINTESTINAL MALIGNANCIES. (E.) Lo Gerfo, P. (Coll. Phys. Surg., Columbia U. New York, N.Y.), F. P. Herter and S. J. Bennett. *Int J Cancer* 9(2):344-348, 1972.

In an attempt to demonstrate patient antibody activity against carcinoembryonic antigen (CEA), antigen-antibody complexes were labeled with ^{125}I and absorbed with zirconyl phosphate gel (Z-gel). The 265 subjects tested included 110 with nonmetastatic colon carcinoma, 122 with other gastrointestinal, breast and pulmonary neoplasms, 20 pregnant women, and 13 healthy volunteers. Sera from 25 of the subjects were also analyzed by Sepharose 6 B column chromatography. Antibody activity directed against CEA could not be detected with either technique. The possibility that CEA-anti-CEA complexes exist and prevent the detection of free antibodies cannot be ruled out, though this situation is reported to occur only in patients with metastatic carcinoma. It is also possible that the specific site of the human antibodies was destroyed during the labeling procedure.

4626 EARLY APPEARANCE OF SERUM α -FETOPROTEIN DURING HEPATOCARCINOGENESIS AS A FUNCTION OF AGE OF RATS AND EXTENT OF TREATMENT WITH 3'-METHYL-4-DIMETHYLAMINOAZOBENZENE. (E.) Kroes, R. (Natl. Cancer Inst., Bethesda, Md.), G. M. Williams and J. H. Weisburger. *Cancer Res* 32:1526-1532, 1972.

Male rats (aged 6-12 weeks, 9 or 15 months) were fed a diet supplemented with 0.06% 3'-methyl-4-dimethylaminoazobenzene (3'-MDAB) for 5, 10 or 20 weeks. Beginning at week 3 of 3'-MDAB feeding, rats were bled and serum was separated and assayed for α -fetoprotein (AFP). Sera from all animals contained AFP by week 3 and remained AFP-positive during 3'-MDAB feeding. When 3'-MDAB was stopped after 5 or 10 weeks, sera remained positive for another 1 or 2 weeks before becoming negative. Sera of rats given 3'-MDAB for only 5 weeks remained AFP-negative for 30 weeks after carcinogen feeding. In some rats fed 3'-MDAB for 10 weeks, sera became AFP-negative by week 13 and 14, after which it

gradually returned to AFP-positive. Serum remained positive without relapse for 19 weeks in one rat given 3'-MDAB for ten wks; this rat had developed a large liver tumor. Age did not affect appearance of AFP, although older rats showed positive serum AFP only at week 4 of the 3'-MDAB diet, a week later than younger rats. Older rats remained AFP-negative after 3'-MDAB feeding longer than younger rats.

4627 RADIOIMMUNOASSAY OF ALPHA-FETOPROTEIN IN PRIMARY AND SECONDARY CANCER OF THE LIVER.

(E.) Ruoslahti, E. (Dept. Serology Bacteriol., U. Helsinki, Finland), M. Seppälä, P. Vuopio, E. Saksela and P. Peltokallio. *J Nat Cancer Inst* 49(3):623-630, 1972.

The serum alpha-fetoprotein (AFP) concentration was determined by radioimmunoassay in 14 primary liver cancers and 17 secondary liver cancers. With this method, unlike any previous one, AFP could be quantitated in all the samples. The AFP levels in 10 of the 14 patients (71%) were one thousand times or more (3.5-840 µg/ml) above the normal serum level. Two sera had intermediate values (100 and 200 ng/ml) and two had normal AFP concentrations (9 and 16 ng/ml). A normal AFP level thus does not exclude the possibility of primary liver cancer. No correlation was found between the AFP level and the degree of malignancy of the tumor. Of the 17 patients with secondary liver cancer, three had an AFP concentration above the normal range. In these, the elevation was moderate, ranging from 60-400 ng/ml.

4628 IMMUNOLOGIC INDUCTION OF MALIGNANT LYMPHOMA: GENETIC FACTORS IN THE GRAFT-VERSUS-HOST MODEL. (E.) Gleichmann, E. (New England Med. Ctr. Hosp., Boston, Mass.), H. Gleichmann and R. S. Schwartz. *J Nat Cancer Inst* 49(3):793-804, 1972.

The development of malignant lymphomas was studied in 47 different donor-recipient pairs undergoing a chronic graft-versus-host reaction, which was induced in F₁ hybrid mice by the injection of parental spleen cells. None of the H-2 compatible combinations developed lymphomas. The development of neoplasms in H-2 incompatible pairs was inhibited by maneuvers designed to diminish the immunologic response of the graft against the host. Whether lymphomas developed in a given donor-recipient pair appeared to depend on: a) a major antigenic (H-2) difference between donor and recipient; b) the inherent (genetic?) ability of the donor's immunocytes to respond to the recipient's antigens; and c) a factor in the recipient, which probably determines susceptibility to oncogenic viruses.

4629 TUMORIGENICITY AND ISOIMMUNIZING PROPERTIES OF C3H MOUSE CELLS UNDERGOING "SPONTANEOUS" MALIGNANT CONVERSION *IN VITRO*. (E.) Kieler, J.

(Fibiger Lab., Copenhagen, Denmark), C. Radzikowski, J. Moore and K. Ulrich. *J Nat Cancer Inst* 48(2): 393-405, 1972.

Three C3H mouse cell lines, derived from embryo, spleen and lung, showed spontaneous malignant transformation *in vitro*. Cells of these transformed lines were injected into C3H and other mice to test for tumorigenicity and to determine whether such injections immunized against transplants of the same cells. The cytotoxicity *in vitro* of sera and lymphoid cells from mice injected with transformed cells was also observed. Transformed cells were tumorigenic; newborn mice were more susceptible than adults. Transformed cells developed isoimmunizing properties, as evidenced by *in vivo* transplantation immunity tests and by *in vitro* cytotoxicity tests with sera and lymphoid cells. Earle's L-929 mouse fibroblasts, the three cell lines which transformed spontaneously plus another such line, and four tumors derived from these cell cultures induced immune cross-reactions in C3H mice in transplantation experiments. Cross-reactions were also seen between the three principal cell lines studied and their corresponding antisera *in vitro*. There was no evidence that the development of common antigenic properties was due to murine leukemia virus, mammary tumor virus, or mycoplasma. Tumors derived from the three cell lines were transplantable into allogeneic hosts, even when hosts were immunized with normal C3H cells, indicating that the appearance of "tumor-associated" isoantigens was followed by the loss or dilution of normal H-2 antigens.

4630 ANTIBODIES TO EPSTEIN-BARR VIRUS (EBV) IN AMERICAN PATIENTS WITH BURKITT'S LYMPHOMA. (E.) Levine, P. H. (Natl. Cancer Inst., Bethesda, Md.), G. T. O'Connor and C. W. Berard. *Cancer* 30(3):610-615, 1972.

Twenty-nine American patients with lymphomas histologically indistinguishable from African Burkitt's lymphoma were studied for antibody to the EBV. Antibody titers were higher in the American Burkitt patients than age-matched normal controls or patients with acute lymphocytic leukemia (ALL), but they were not as high as the African Burkitt patients. All cases with typical histologic features and adequate pathologic material (including imprints) were positive for antibody to EBV. The young American Burkitt patients (less than 8 yr old) had particularly high titers with a geometric mean titer of 1:425 compared to 1:11 for the matched ALL group and 1:4 for the normal controls. These studies indicate that American Burkitt patients, like those in Africa, have elevated EBV antibody levels and provide another similar parameter suggesting that American and African Burkitt's lymphoma are the same disease.

4631 GROUP- AND TYPE-SPECIFIC ANTIGENS IN MOUSE LEUKAEMIA INDUCED BY FRIEND, MAZURENKO

D RAUSCHER VIRUSES. (E.) Mazurenko, N. P. (Acad. d. Sci., Moscow, USSR) and V. E. Gurtsevich. *oplasma* 19(4):277-282, 1972.

Leukemias of different morphological types were induced in CC57Br mice by i.p. injections of zurenko, Friend of Rauscher virus preparations. Tumor-specific antigen (GSA) in organs of leukemic mice was determined by microprecipitation in agar using rabbit antisera and type-specific antigen (TSA) by immunofluorescence. GSA was found in liver, spleen, thymus, lymph nodes, lungs, kidneys and plasma of all mice with virus-induced leukemias, regardless of the morphological form those leukemias took. No GSA was found in cardiac muscle or brain tissue. TSA was found in spleen, thymus and lymph nodes of all leukemic mice. GSA first appeared in Friend virus-infected mouse plasma on day 8 postinfection; TSA was first observed in spleen and bone marrow of these mice on the 7-8 days postinfection. Plasma GSA and spleen TSA appeared simultaneously on day 7 in mice infected with Rauscher virus.

32 GIANT FOLLICULAR LYMPHOCYTOMA OF THE SPLEEN: STUDY ON IMMUNOGLOBULIN FORMATION AND DISPERBANCE IN IT CAUSED BY NEOPLASMS. (Ger.) Ott, H. (Klinik Hosp., Stuttgart, West Germany). *Med Welt* (50):1996-1997, 1971.

Structural changes in the spleen of a 65-year-old man with Brill-Symmers disease are described. Splenectomy caused no change in serum proteins and the immunoglobulin levels remained within normal limits. The conditions under which malignant follicular lymphomas would cause a deficiency in the humoral immune system are discussed. The presence of germinal centers (germinocytes and germinoblasts) as controlling factors for follicular structure is stressed and the question is raised whether the absence of germinocytes and germinoblasts, which are responsible for the development of plasma cells and gammaglobulin, will cause hypo- and agammaglobulinemia. It is stressed that localized follicular lymphoma frequently changes to lymphatic leukemia, which is accompanied by a decrease in gammaglobulins. It is also postulated that in cases of acquired agammaglobulinemia, which is accompanied by a hypertrophy of germinal centers and lymphoid tissue, a blocking of plasma cells and immunoglobulins occurs in the thymus-independent immune system.

3 RESPONSE OF SYNGENEIC MURINE LYMPHOMATA TO IMMUNOTHERAPY IN RELATION TO THE ANTIGENICITY OF THE TUMOUR. (E.) Parr, I. (Chester Beatty Res. Inst., Surry, England). *Brit J Cancer* 26(3):181-182, 1972.

Responses of four murine lymphomata, transplanted to their syngeneic hosts and differing widely in their biological properties such as tendency to metastasize and "strength" of tumor specific antigen, to immuno-

therapy, were investigated. Following the injection of a known number of tumor cells, the mice were treated either by administration of irradiated tumor cells, living BCG or both. In general, the response to BCG alone was small even in the most responsive tumors, irradiated cells were more effective and the best results were obtained by a combination of the two procedures. "Cures" were only obtained with the most antigenic of the tumors tested and then only when the live tumor cells were inoculated i.p. The effect of these treatments on the rate of growth of tumor when the cells were given s.c. was small but the rate at which metastatic spread occurred from the s.c. site was slowed and for one of these tumors this was quite marked.

4634 LUNG CARCINOMA OF SHEEP (JAAGSIEKTE). III. LYMPH NODE, BLOOD, AND IMMUNOGLOBULIN. (E.) Hod, I. (Hebrew U., Rehovot, Israel), K. Perk, T. A. Nobel and U. Klopfer. *J Nat Cancer Inst* 48(2):487-507, 1972.

Tumor, lymph nodes and serum samples from 12 adult sheep with pulmonary carcinoma (jaagsiekte) were examined chemically and under the electron microscope. Normal lymph node architecture in sheep with jaagsiekte was deranged; lymphocyte depletion was marked (especially in mediastinal nodes), germinocytes were depleted, and plasmacytosis was seen as was reticulocytosis. In electrophoretic studies of serum proteins of sheep with jaagsiekte, a rise in β_1 and in total γ globulin fractions was seen, accompanying a rise in total proteins. Fast-moving serum lipoproteins were decreased in tumor-bearing sheep, while slow-moving lipoproteins were increased. Ultracentrifuge and immunoelectrophoretic studies suggested that the hyperglobulinemia in jaagsiekte sheep occurred mainly in the 7S IgG fraction. In immunofluorescence tests, few tumor cells reacted positively against normal sheep sera and sera from tumor-bearing sheep. Even fewer tumor cells reacted positively against fluorescein isothiocyanate-tagged antisheep globulin anti-serum applied directly to tumor cells. In gel diffusion tests, precipitation lines between sheep sera and tumor cell extracts were not seen.

4635 IDENTITY OF THE SOLUBLE EVB-ASSOCIATED ANTIGENS OF HUMAN LYMPHOID CELL LINES. (E.) Reedman, B. M. (Queensland Inst. Med. Res., Brisbane, Australia), J. H. Pope and D. J. Moss. *Int J Cancer* 9(1):172-181, 1972.

Lymphoid cell lines from patients with acute myeloid leukemia (QIMR-WIL), Burkitt lymphoma (QIMR-GOR and Raji), infectious mononucleosis (QIMR-STE) and thymus cells transformed by Epstein-Barr virus (EBV) (TFT-1) were reacted in immunodiffusion (ID) tests against human sera from different sources. All lymphoid cell lines except Raji contained EBV. Two precipitation lines, S and F, were seen in ID tests of QIMR-WIL cells. With soluble antigen, the S line occurred but not the F line. Gamma globulin produced both lines

when tested against the QIMR-WIL cells; this suggested that the two lines were due to antigen-antibody reactions. The S line, which was produced with soluble antigens from TFT-1, Raji, QIMR-STE and QIMR-GOR as well as QIMR-WIL cells, appeared to be associated with EBV. Furthermore, the capacity of soluble antigens to produce the S line was related to the complement fixing (CF) activity of the antigen. Crude antigens prepared from HeLa cells, fetal thymus fibroblasts and melanoma cells gave weak reactions with some sera but were not identical to the S line. Ninety-five percent of sera negative in immunofluorescence (IF) tests with QIMR-WIL antigen were also negative in CF tests. The S line reaction was rare in sera lacking IF and CF antibody, but the F line reaction was common in such sera. The CF and ID antigens were thought to be at least partially identical. When QIMR-WIL antigen was fractionated and reacted against five sera, the distribution and concentration of the antigen responsible for the S line reaction was similar to that of a heat-resistant soluble CF antigen.

- 4636 EFFECT OF IMMUNOSUPPRESSION OF THE DEVELOPMENT OF THE ADJUVANT-INDUCED GRANULOMA IN MICE. (E.) Krueger, G. R. F. (Natl. Cancer Inst., Bethesda, Md.). *Path Microbiol* 37(6):436-448, 1971.

Female C₃H/HeN, BALB/c, C57Bl and Swiss mice were sensitized with complete Freund's adjuvant (CFA) and immunosuppressed with thymectomy, azathioprine or antilymphocyte serum (ALS). The development of granulomas following sensitization was studied and correlated with cutaneous delayed hypersensitivity. Only slight differences between mouse strains were observed. Thymectomy caused a significant decrease in lymphocytes and foamy phagocytes at the site of inflammation. Granulocytes and activated mesenchymal cells predominated. Cellular response at a second site of sensitization was the same. Lymphocyte reduction was less marked following azathioprine treatment, especially after a second sensitization. Lymphoid cells and small basophilic reticulum cells predominated. ALS treatment produced a moderate to marked depression of lymphocyte infiltration in both the first and second CFA sensitizations. Plasmacytoid cells increased after the second sensitization. All the immunosuppressive treatments caused a reduction in the number of draining lymph nodes in small lymphocytes. Secondary follicles increased in thymectomized mice, decreased in azathioprine-treated mice and were unchanged in ALS-treated mice. Medullary cord plasma cells were numerous in thymectomized mice, decreased in azathioprine-treated mice and absent in ALS-treated mice. The incidence of immature plasmacytes was inversely proportional to the number of medullary cord plasma cells. Thymectomy and ALS had the greatest effects on delayed hypersensitivity; azathioprine produced a less specific cellular response. Immunosuppression did not increase dissemination of granulomatous lesions.

- 4637 STUDIES OF CARCINO-FETAL PROTEINS. III. DEVELOPMENT OF A RADIOIMMUNOASSAY FOR α -FETOPROTEIN. DEMONSTRATION OF α -FETOPROTEIN IN

SERUM OF HEALTHY HUMAN ADULTS. (E.) Ruoslahti, E. (U. Central Hosp., Helsinki, Finland) and M. Seppala. *Int J Cancer* 8:374-383, 1971.

A new radioimmunoassay for serum α -fetoprotein (α -FP) is described. α -FP was iodinated and ¹²⁵I-labeled α -FP was extracted and reacted with anti- α -FP antisera. Standard curves for the inhibition of binding of labeled α -FP by antibody were obtained and the inhibition of this activity by normal and hepatoma patients' sera was tested. The sensitivity limit of the radioimmunoassay was 250 pg of α -FP/ml serum, while that of the older immunodiffusion test for α -FP was 10 μ g α -FP/ml serum. Hepatoma sera were α -FP-positive in immunodiffusion at dilutions of 1:80; these sera were positive at dilutions of up to 1:200,000 in the new assay. The new assay completely covered the thousandfold concentration gap between α -FP levels in normal human serum and levels detectable by immunodiffusion. Evidence yielded by the radioimmunoassay for the presence of α -FP in normal human sera was as follows. Normal sera at dilutions of 1:5 inhibited the binding of labeled α -FP by antibody. This inhibition could be abolished by treating normal sera with anti- α -FP immunoadsorbent. Elution of these immunoadsorbents at pH 2.5 revealed that they had bound α -FP activity from normal sera. Finally, after fractionation of normal sera by electrofocusing the activity inhibiting the radioimmunoassay was present in a fraction having the isoelectric point of fetal α -FP.

- 4638 SOME ASPECTS OF THE IMMUNE DEFENSE AGAINST CANCER. II. *IN VITRO* STUDIES ON HUMAN TUMORS. (E.) Hellström, I. (U. Washington Med. Sch., Seattle) and K. E. Hellström. *Cancer* 28(5):1269-1271, 1971.

Studies of lymphocyte-mediated antitumor reactions in human subjects are summarized. Peripheral blood lymphocytes from patients with growing neuroblastomas inhibited cultivated neuroblastoma cells; inhibition occurred with both autochthonous cells and neuroblastic cells from other patients, indicating that neuroblastomas possess common tumor-associated antigens. Sera from the neuroblastoma patients blocked destruction of cultured neuroblastoma cells by immunologically active lymphocytes. Lymphocytes from patients with other types of tumors were able to destroy cultivated autochthonous tumor cells of the respective types. Morphologically similar tumors were found to cross react. Normal cells from the tumor patients were not destroyed by lymphocytes affecting the neoplastic cells, indicating antigenic differences between normal and tumor cells from the same patient. A correlation exists between progressive tumor growth *in vivo* and blocking serum activity *in vitro*; 67 of 81 patients with growing tumors had blocking sera, while sera from only three of 19 symptom-free patients were blocking. Sera from patients in remission were able to reverse blocking activity of sera from other patients with the same type tumor. Further experiments may determine the possibility of immunologic prevention of tumors.

- 639 STUDIES ON BLASTIC TRANSFORMATION OF LYMPHOCYTE CULTURES IN CHRONIC LYMPHOCYTIC LEUKEMIA. (Pol.) Pluzanska, A. (Acad. Med., Lodz, Poland), Kulesza, E. Krykowski, H. Koeppe and H. Jaworska. *Rad Lek* 24(21):2017-2022, 1971.

PHA-stimulated blastic transformation in 3- and 5-day-old lymphocyte cultures obtained from 35 patients with chronic lymphocytic leukemia (10 mild, group I; 16 moderately severe, group II; 9 severe, group III) was much lower (0-21.5%, mean 6.42%, on day 3; 2.2-29.5%, mean 9.5%, on day 5) than in cultures from 20 healthy controls (62-80%, mean 70.5%). There was no significant correlation with severity of disease (6.7%, 6.5% and 5.9% on day 3 in groups I, II and III, res.), although complete absence of transformed cells was seen more frequently in group III, and no correlation with treatment or alpha₂ or gamma globulin levels. There seemed to be a slight correlation between degree of depression and duration of disease (4.7% in those with > 3 years duration) and degree of leukocytosis (3% in those with > 100,000/mm³ as compared with 8.2% in those with < 10,000/mm³). It is suggested that blastic transformation in 3-day cultures has no prognostic value.

- 40 IMMUNOLOGICAL STUDY OF CEREBRAL TUMORS *IN VITRO*. (Fr.) Febvre, H. (Sainte-Anne Hosp. Paris, France), R. Maunoury and J. P. Constans. *Neuro-chirurgie* 17(3):203-207, 1971.

Immunological reactions of normal human embryonic liver and brain cells, human embryonic cells transformed *in vitro* by Rous sarcoma virus (RSV), cell lines from human glioblastomas and astrocytomas, and three lines of tumor cells of extracerebral origin were compared by immunofluorescence, mixed agglutination tests, and the delayed hypersensitivity test. Tumor cells isolated from primary brain tumors and human embryonic cells transformed by RSV displayed positive immunofluorescence reaction with human serum, while all normal human cell lines and lines derived from extracerebral tumors gave negative results. The results from mixed agglutination tests were the same. In patients who had undergone surgery for primary brain tumors and had been hyperimmunized with their own tumor, strong intradermal reactions were produced by antigens prepared from malignant glial tumors and embryonic cells transformed *in vitro* by RSV; antigens from extracerebral tumors gave weak reactions.

- 1 LYMPHOCYTE TRANSFORMATION IN IMMUNOPROLIFERATIVE DISORDERS. (E.) Catovsky, D. (Royal Brompton Med. Sch., London, England), P. J. L. Holt and D. A. G. Galton. *Brit J Cancer* 26(3):154-163, 1972.

Lymphocyte transformation with phytohemagglutinin (PHA) studied in 30 patients with immunoproliferative

disorders (lymphoproliferative and plasma cell disorders). Lymphocyte transformation at three days was reduced in the lymphoproliferative disorders (chronic lymphocytic leukemia (CLL), well-differentiated (lymphocytic) follicular lymphoma (FLL) and Waldenström's macroglobulinemia (WM)), and normal in the plasma cell disorders (myelomatosis, primary systemic amyloidosis, α-chain disease and benign monoclonal gammopathy) and in idiopathic cold hemagglutinin disease. A case of plasma-cell leukemia with increased numbers of abnormal cells in the circulation also showed reduced transformation. It is suggested that the presence in the circulation of abnormal lymphocytes (or plasma cells) accounts for the results in CLL and FLL, WM and plasma-cell leukemia. In WM a correlation was found between the activity of the disease (expressed by the levels of IgM paraprotein) and the degree of blast transformation. The long-term (28 days) *in vitro* survival of lymphocytes using subconcentrations of PHA was also studied in seven patients. The cell populations (PHA-non-responsive) of CLL and FLL, but not of WM, had a good *in vitro* survival, resembling in this respect the normal PHA-responsive population of lymphocytes, but they remained PHA-non-responsive after four weeks' culture. It is speculated that in CLL the long survival *in vitro* of the PHA-non-responsive (leukemic) population corresponds to their long life-span *in vivo*.

- 4642 EVOLUTION OF CELL-MEDIATED ANTITUMOR IMMUNITY IN MICE BEARING A SYNGENEIC CHEMICALLY INDUCED TUMOR: INFLUENCE OF TUMOR GROWTH, SURGICAL REMOVAL AND TREATMENT WITH IRRADIATED TUMOR CELLS. (E.) Belehradsky, J., Jr. (Gustave-Roussy Inst., Villejuif, France), G. Barski and M. Thonier. *Int J Cancer* 9:461-469, 1972.

Male C57BL/6 mice were given an immunizing injection s.c. of living cells of an undifferentiated, 3-methylcholanthrene-induced sarcoma (TBL CL2). Peritoneal cells (PC) were taken from immunized mice at various times after immunization and incubated with TBL CL2 cells; the inhibition of colony growth (CGI) *in vitro* by PC was observed. PC harvested seven days after inoculation of tumor cells showed strong CGI activity; the average number of colonies in TBL CL2 cultures was reduced 95% by these PC. No CGI was seen for PC taken 23 days after tumor inoculation. Mice entered an "eclipse" stage after an initial induction of immunological activity for their PC. This eclipse state lasted until mice were killed at day 60 after immunization. However, when TBL CL2-induced tumors were excised 39 days after tumor inoculation, CGI activity for PC was restored by 68-75 days after tumor resection. When mice whose tumors had been removed were given injections of X-irradiated TBL CL2 cells (9,000 R), CGI activity was restored by seven days after the injection of the irradiated cells. An *in vivo* study of tumor graft rejection showed a parallelism with CGI tests. Grafts were rejected in mice bearing TBL CL2 tumors for ten days and having immunologically active PC; grafts were not rejected in tumor-bearing mice whose PC were immunologically "eclipsed".

- 4643 IMMUNE REACTIVITY OF LEUKEMIA PATIENTS TO AUTOLOGOUS BLAST CELLS. (E.) Levanthal, B. G. (Natl. Cancer Inst., Bethesda, Md.), R. H. Halterman, E. B. Rosenberg and R. B. Herberman. *Cancer Res* 32:1820-1825, 1972.

Twenty patients with acute leukemia were studied by three assays, the mixed leukocyte culture, lymphocyte cytotoxicity assay, and skin tests, for evidence of immune reactivity against their own leukemic blast cells. All but one showed a positive response in at least one assay, with mixed leukocyte culture positive in 17 of 20, lymphocyte cytotoxicity assay positive in 8 of 16, and skin test positive in 13 of 18 patients at some point in the course of their disease. The skin test seemed to correlate with disease state. It was positive 14 of 18 times when performed in remission and only 3 of 8 times in relapse. Positive reactions in the mixed leukocyte culture tended to be most common 10 to 20 days after chemotherapy had been discontinued. The tests did not correlate well with one another. Presumably, they measure different phases of the immune response with differing sensitivity to such variables as chemotherapy. These studies indicate that immune reactivity of patients to their own leukemia cells does exist and can be assayed as an important new measure of the effect of therapy on the patient.

- 4644 SERUM α -FETOPROTEIN AS A BIOCHEMICAL MARKER FOR HEPATOCELLULAR CARCINOMA. (E.) McIntire, K. R. (Natl. Cancer Inst., Bethesda, Md.), C. L. Vogel, G. L. Princler and I. R. Patel. *Cancer Res* 32:1941-1946, 1972.

The demonstration of α -fetoprotein (α FP) has proven value in the diagnosis of hepatocellular carcinoma, but little is known of the dynamics of this protein during the course of the disease. A sensitive, quantitative test has been used to measure α FP serum levels in 90 Ugandan patients with histologically proven hepatocellular carcinoma. By the standard double diffusion immunological test, 71% of the patients were α FP positive. The quantitative values were spread over a wide range from 0.5 to 4000 μ g/ml, with a median value of 71 μ g/ml. Forty-one patients (26 before treatment and 15 during chemotherapy) were followed with serial serum α FP determinations. There was a remarkable stability in the level for each patient, which levels showed little fluctuation during the time they were followed, regardless of the initial level. The only consistent change was a slight tendency for the serum α FP to rise as the disease progressed. A striking difference was noted in four patients receiving partial hepatectomy who showed a rapid decline in serum α FP and became negative postoperatively.

- 4645 EFFECT OF HOST STRAIN AND H-2 TYPE ON SPONTANEOUS REGRESSION OF MURINE LEUKEMIA. (E.) Dietz, M. (Michigan Cancer Fdn., Detroit) and M. A. Rich. *Int J Cancer* 10:99-104, 1972.

Mice of 14 different strains, representing six different H-2 antigenic types, were inoculated i.p. with either of two Friend leukemia viruses, one of which induced leukemias which often regressed (RFV) and one of which was conventional (CFV). The leukemia incidence and the latent period of leukemia development were observed. For each mouse strain the responses to RFV and to CFV were similar in regard to latent period. Mice with the H-2^d and H-2^b alleles were most susceptible to CFV leukemogenesis; mice with the H-2^k and H-2^a alleles showed an intermediate susceptibility to CFV, and mice with the H-2^b allele were resistant. Leukemia regressed in ten of 12 mouse strains susceptible to RFV. Leukemias regressed in RFV-inoculated mice homozygous for all the H-2 types save H-2^b. Regression of leukemias in CFV-inoculated mice was most often seen in mice homozygous for the H-2^k allele. In general, those strains which were more refractory to leukemia induction by RFV and CFV showed the highest incidences of regression. It was concluded that the H-2 locus was not a determinant of leukemia regression.

- 4646 INTERACTION OF PHYTOHEMAGGLUTININ AND CONCAVALIN A WITH TRANSPLANTABLE MOUSE LYMPHOMAS OF DIFFERING MALIGNANT POTENTIAL. (E.) Dent, P. B. (Dept. Pediat. Biochem., McMaster U., Hamilton, Canada) and B. L. Hillcoat. *J Nat Cancer Inst* 49(2):373-377, 1972.

The effects of phytohemagglutinin (PHA) and concanavalin A (con A) on DNA synthesis and agglutination in three mouse lymphoma lines with differing degrees of malignancy were investigated. The Gross virus-induced A Ascites lymphoma was the most highly malignant, the mean survival time of female C3H/HeJ mice being 8.8 ± 2 days after i.p. injection of 5×10^6 cells. Injection of the same number of LS₂ transplantable lymphoma cells resulted in a mean survival time of 15.7 ± 0.7 days. None of the mice injected with LM₄ transplantable lymphoma cells died. *In vitro* agglutination tests showed that all three lines gave the same response in con A or PHA. However, differences were seen in the effect of the agglutinins on DNA synthesis as measured by the rate of ³H-thymidine incorporation. While con A inhibited DNA synthesis in all three tumor lines to the same extent, PHA inhibited DNA synthesis in A Ascites cells to a greater extent than in the LS₂ and LM₄ lines. In spite of the differential effects of PHA on DNA synthesis, no significant differences were observed in binding of ¹²⁵I-labeled PHA to the tumor cell membranes.

- 4647 COMPLEMENT-FIXING ANTIGENS OF HERPES SIMPLEX VIRUS TYPES 1 AND 2: REACTIVITY OF CAPSID, ENVELOPE, AND SOLUBLE ANTIGENS. (E.) Martin, M. L. (Ctr. Dis. Control, Atlanta, Ga.), E. L. Palmer and R. E. Kissling. *Infect Immun* 5(2):248-254, 1972.

Capsid complement-fixing (CF) antigens were prepared

from herpes simplex virus (HSV) types 1 and 2 by dissociating the viral envelope from the virus particle by detergent treatment; envelope CF antigen was prepared by treating HSV of both types with ether and high pH. Soluble HSV CF antigens were prepared in culture fluids of untreated HSV-infected rabbit or monkey cells. Antigens of the three types from the two HSV serotypes were reacted in CF tests against anti-capsid antigen, anti-envelope antigen or anti-soluble antigen guinea pig or rabbit antisera prepared against HSV-type 1 or -type 2 antigens. HSV-type 1 and -type 2 capsid antigens were highly cross-reactive in CF with antisera against capsid antigen; cross-reactivity was also seen for envelope and soluble antigens. In some cases, however, antisera to an antigenic component of HSV-type 1 reacted more strongly with HSV-type 1 antigen than with HSV-type 2 antigens. Soluble antigens of both HSV serotypes cross-reacted with antisera produced against crude HSV in infected animals; antibody titers of 1:32 to 1:64 were seen. However, sera from humans infected with crude HSV had low soluble antigen antibody titers ($\leq 1:8$). The HSV CF antigens did not react with anti-varicella virus antiserum, but did react with anti-herpes virus type B antiserum. In sera from normal human donors, titers of antibody to HSV reference egg antigen and to HSV capsid antigen were higher than titers to HSV envelope antigen, which in turn were higher than titers to HSV soluble antigen.

648 RADIOIMMUNE ASSAY OF CARCINOEMBRYONIC ANTIGEN. (E.) Egan, M. L. (City Hope Natl. Med. Ctr., Duarte, Calif.), J. T. Lautenschleger, E. E. Coligan and C. W. Todd. *Immunochem* 9:289-299, 1972.

A modified radioimmune assay for carcinoembryonic antigen (CEA) is described; the assay is based on the double antibody technique. Three γ -emitters are used; ^{125}I to follow CEA precipitation, ^{131}I to monitor the precipitation of goat anti-CEA antiserum, and ^{22}Na as a volume marker for residual supernate. A computer program has been developed to facilitate calculation of assay data. The assay has been shown to be capable of measuring CEA in amounts as low as 3-70 ng.

649 FACILITATION OF POLYOMA TUMOR GROWTH IN RATS BY BLOCKING SERA AND TUMOR ELUATE. (E.) Mansal, S. C. (Fred Hutchinson Cancer Ctr., Seattle, Wash.), R. Hargreaves and H. O. Sjögren. *Int J Cancer* (1):97-108, 1972.

Intraperitoneal inoculation of rats with blocking material in the form of serum from rats bearing polyoma virus-induced PW13 tumors or eluates of polyoma tumor tissue enhanced growth of PW13 isografts. Eluates of a 3-methylcholanthrene (MCA)-induced tumor and eluates of normal kidney tissues from PW13-bearing rats did not facilitate tumor growth. In related experiments, blocking serum and tumor and normal kidney eluates were tested for ability to abrogate the cyto-

toxicity of polyoma tumor-bearing rats' lymphocytes for polyoma tumor target cells *in vitro*. Eluates from polyoma tumor tissue blocked lymphocyte cytotoxicity, but MCA tumor eluates and normal kidney eluates from polyoma tumor-bearing rats had no detectable blocking activity. Blocking serum also abolished lymphocyte cytotoxicity for polyoma tumor target cells. Blocking activity of polyoma tumor eluates was detectable in sera of recipients for three days after administration of eluates. There were no differences in levels of cell-mediated cytotoxicity of lymphocytes for target tumor cells between rats given blocking serum and rats given polyoma tumor eluates.

4650 DETECTION OF CELLULAR IMMUNITY TO TUMOR ANTIGENS OF A GUINEA PIG HEPATOMA BY INHIBITION OF MACROPHAGE MIGRATION. (E.) Churchill, W. H. (Natl. Cancer Inst., Bethesda, Md.), B. Zbar, J. A. Belli and J. R. David. *J Nat Cancer Inst* 48(2):541-549, 1972.

Hepatomas were induced in guinea pigs by diethylnitrosamine in drinking water; cells of these tumors (line-1 cells) were mixed, to a proportion of 10% line-1 cells, with peritoneal exudate cells from guinea pigs which had been immunized against line-1 tumors by multiple injections of tumor cells. Macrophage migration was inhibited in mixtures of line-1 cells and immune peritoneal exudate cells; migration from such mixtures was 41% the rate of migration of immune cells alone. Migration in mixtures of line-1 tumor cells and unimmunized animals' peritoneal exudate cells was 107% the migration rate for immune peritoneal exudate cells alone. Normal spleen cells and peritoneal exudate from guinea pigs with the line-7 tumor did not affect macrophage migration when mixed with line-1 cells. Lymphocytes, purified from peritoneal exudate cells harvested from guinea pigs immunized against line-1 tumors, produced macrophage migration inhibition factor in response to tumor cell antigens. Pretreatment of line-1 cells with trypsin did not alter their inhibitory effect on macrophage migration. Cells treated by X-irradiation (5000 R) or stored in liquid nitrogen after slow freezing also retained their ability to inhibit macrophage migration.

4651 ANTIGENIC COMPARISON OF BOVINE TYPE C VIRUS WITH MURINE AND FELINE LEUKEMIA VIRUSES. (E.) Ferrer, J. F. (Sch. Vet. Med., U. Pennsylvania, Kennett Square). *Cancer Res* 32:1871-1877, 1972.

Bovine Serum 27-125 (spontaneous regression case of leukemia), which contains antibodies to a type C virus found in bovine cultures [New Bolton Center (NBC) cell lines], did not react in immunofluorescence tests with rat cells transformed by and releasing abundant quantities of murine leukemia viruses. In addition, these rat cells did not remove the immunofluorescence activity of Serum 27-125 for virus-containing NBC cells. Negative results were also obtained when three rat antisera containing antibodies to most, if not all,

the known antigens of the murine leukemia-sarcoma viruses, including the group-specific (*gs*) antigens, were tested by immunofluorescence on NBC cultures showing relatively high proportions of cells with the bovine virus immunofluorescence antigen. Two anti-feline leukemia virus sera, with strong anti-*gs* antigen activity, also failed to react with the NBC cultures. Repeated absorption with large numbers of disrupted NBC cells did not remove the immunofluorescence activity of one of the anti-feline leukemia virus sera for *gs-3* antigen contained in a rat lymphoma. Immunodiffusion experiments with the anti-murine leukemia virus and anti-feline leukemia virus sera also failed to reveal the *gs* antigens in Tween-ether-treated and concentrated preparations of cells and/or pellets of culture fluids from the virus-producing NBC cell lines. These preparations did not remove the anti-*gs*-precipitating activity of an anti-murine leukemia virus serum either. The results of both immunofluorescence and immunodiffusion studies indicate that the type C virus of the NBC cell lines is an indigenous bovine virus which is antigenically unrelated to the known mammalian type C viruses. These findings suggest the possibility that leukemia in cattle and perhaps in other species may be caused by a family of type C viruses different from that of the presently known leukemia viruses.

- 4652 DEMONSTRATION OF CELLULAR IMMUNITY TO TUMOR-SPECIFIC ANTIGENS OF MALIGNANT MELANOMA IN HAMSTERS BY INHIBITION OF MACROPHAGE MIGRATION. (E.) Henderson, W. R. (U. California Sch. Med., San Francisco), K. Fukuyama, W. L. Epstein and L. E. Spittler. *J Invest Derm* 58(4):229-232, 1972.

Delayed hypersensitivity of Golden Syrian hamsters to melanoma-specific tumor antigens was demonstrated by a technique employing the inhibition of macrophage migration *in vitro*. Migration of peritoneal exudate cells from animals immunized by injection with cell-free inocula of hamster melanoma was inhibited when these cells were incubated with cultured melanoma cells. In contrast, the migration of peritoneal exudate cells from normal nonimmunized controls was unaffected when incubated with melanoma cells. A decreased migration rate was also observed with peritoneal exudate cells from animals, inoculated with melanoma supernatant, who never developed tumors and with peritoneal exudate cells from animals who had had their tumors removed 3, 9 and 16 days before testing.

- 4653 IMMUNOGENICITY OF LEUKEMIA L1210 CELLS AFTER NEURAMINIDASE TREATMENT. (E.) Bekesi, J. G. (Roswell Park Mem. Inst., Buffalo, N.Y.), G. St. Arneault and J. F. Holland. *J Nat Cancer Inst* 49(1):107-118, 1972.

L1210 DBA/2 mouse leukemia cells were incubated with various concentrations of neuraminidase from *Vibrio cholerae* before being used to immunize mice with i.p. injections. The release of sialic acid from

neuraminidase-treated L1210 cells, and the immunity conferred on mice by these cells to challenge injections of L1210 cells, were observed. Tumor cells not treated with neuraminidase, and tumor cells treated with neuraminidase in concentrations of 10 IU or less, released negligible sialic acid, and did not protect mice against L1210 cell challenge; all challenged mice treated with these cells died. Neuraminidase concentrations of 20-50 IU/2.5 x 10⁷ L1210 cells/ml incubation medium caused rapid sialic acid release and optimal protection; in mice immunized with these cells, oncogenicity was lost and immunized mice survived challenge with 10⁵ L1210 cells (100,000 times the LD₅₀ for this tumor). Incubation of L1210 cells with more than 75 IU neuraminidase caused loss of oncogenicity but also abolished the immunogenicity of the cells, as evidenced by decreasing resistance to challenge among immunized mice. Treatment with neuraminidase caused a significant release of protein-bound sialic acid, e.g., *N*-acetylneuraminic acid and *N*-glycolylneuraminic acid. Radioactive glycoprotein was also released. Neuraminidase other than that from *V. cholerae* did not eliminate the oncogenicity of L1210 cells.

- 4654 IMMUNOFLUORESCENCE TESTS FOR ANTIBODIES TO EPSTEIN-BARR VIRUS WITH SERA OF LOWER PRIMATES. (E.) Dunkel, V. C. (Natl. Cancer Inst., Bethesda, Md.), T. W. Pry, G. Henle and W. Henle. *J Nat Cancer Inst* 49(2):435-440, 1972.

Sera from seven species of old-world monkeys, two species of new-world monkeys and one species of Prosimian were tested by indirect immunofluorescence for antibodies against Epstein-Barr virus (EBV) and EBV-antigens. Using acetone-fixed P3HR-1 and EB-3 cells, no immunofluorescence was observed with sera from the Prosimian and two new-world monkeys (owl and squirrel). Sera from all species of old-world monkeys tested gave positive reactions with anti-monkey γ -globulin conjugate. However, differences in reactivity were observed when these same sera were tested with antihuman IgG conjugate, the greatest differences occurring with sera from talapoin and African green monkeys. No differences in reactivity between the two conjugates were observed when they were tested on EB-3 cells with human sera from patients with EBV-related diseases and other malignancies and from normal controls. Thus, the variation with primate sera was apparently not the result of limited reactivity of the sera with the antihuman IgG conjugate.

- 4655 TUMOR-SPECIFIC VACCINE CONTAINING MYCOBACTERIUM BOVIS AND TUMOR CELLS: SAFETY AND EFFICACY. (E.) Bartlett, G. L. (Natl. Cancer Inst., Bethesda, Md.) and B. Zbar. *J Nat Cancer Inst* 48(6):1709-1726, 1972.

Guinea pigs were injected with line-10 hepatocellular carcinoma cells and resultant papules were excised; other animals were given irradiated

12,000 rads) line-10 cells, mixed irradiated line-0 cells and bacillus Calmette-Guerin (BCG) or mixed viable line-10 cells and BCG. Twenty-one days later, guinea pigs were challenged with 10^6 viable line-10 cells and immunity to challenge was observed. In delayed cutaneous hypersensitivity tests, only animals immunized with the irradiated tumor cells and BCG evidenced a hypersensitivity reaction. Tumor growth at the challenge site was retarded only in animals given vaccines of viable line-10 cells plus BCG. This vaccine produced regression of palpable malignant tumor in animals challenged with 10^5 line-10 tumor cells; the vaccine did not produce tumor regression, however, when challenge inocula contained 10^7 cells. Five animals immunized with line-10 cells plus BCG showed relapse into tumors after regression or tumor stasis. Relapse tumors were antigenically similar to the original tumors against which guinea pigs were protected by the line-10-BCG vaccine. Guinea pigs were not protected against tumor challenge by irradiated line-10 cells alone or by viable line-10 cells emulsified in Freund's complete adjuvant. Vaccines containing viable line-10 cells and BCG sometimes caused tumors in guinea pigs with tumors at a distant site. Repeated injections of vaccine or a larger proportion of line-10 cells in vaccines did not improve the therapeutic effect of vaccines.

4656 A FACTOR THAT CAN BE USED TO REGULATE AN *IN VITRO* PRIMARY IMMUNE RESPONSE. (E.) Watson, J. (Salk Inst. Biol. Stud., San Diego, Calif.) and M. Roman. *Proc Nat Acad Sci USA* 69(3):594-598, 1972.

A factor that supports stimulation of primary immune response against erythrocyte antigens in deficient mice did not support an *in vitro* primary immune response) fetal bovine serum (FBS)(5%) cultures in Eagle's medium was isolated from culture supernatants of mouse spleen cells infected with Rauscher leukemia virus. The factor was precipitated, dialysed with buffer and collected in fractions (Sephadex G-100) indicated as components I and II. Secondary but not primary immune responses, *in vitro*, were induced in spleen cell cultures supplemented with deficient FBS. The survival of spleen cell types in culture with normal FBS was identical with that in deficient FBS. However, when culture medium without serum was incubated 24 hr with the leukemia virus-infected cell lines (JLS-V5, ML-1, ML-2), an *in vitro* primary immune response was stimulated in the spleen cell cultures with deficient FBS. After fractionation, most activity was found associated with component I (m.w.~100,000). The kinetics of induction of the primary immune response with deficient FBS cultures and various component I concentrations were studied. The immune response *in vitro* with 25 and 100 μ g of component I was identical to the response in cultures using normal FBS. Decreased concentration of component I caused an increase in the lag period before proliferation of PFC (plaque-forming cells). The number of PFC decreased at the peak of the response but remained constant during the proliferative phase for all concentrations of component I. The rate of appearance of PFC de-

creased in the absence of component I. Some specific properties of component I are its antigen-dependent *in vitro* primary response, its ability to restore a lost activity only (does not stimulate response when added to normal FBS spleen cell cultures), its inability to substitute for FBS in stimulating primary immune response *in vitro* and its inability to affect *in vitro* secondary immune response in spleen cultures with deficient FBS.

4657 DELAYED CUTANEOUS SENSITIVITY REACTIONS TO EXTRACTS OF AUTOLOGOUS MALIGNANT MELANOMA: A SECOND LOOK. (E.) Bluming, A. Z. (Natl. Cancer Inst., Bethesda, Md.), C. L. Vogel, J. L. Ziegler and J. W. M. Kiryabwire. *J Nat Cancer Inst* 48(1):17-24, 1972.

Skin tests for delayed cutaneous sensitivity reactions were performed on 16 patients with malignant melanoma (seven men; nine women); skin test antigens included autologous tumor extract (ATE), normal autologous skin extract (ASE), tuberculin, streptokinase-streptodornase, mumps and dermatophyton. Eleven skin tests were positive with ATE as antigen; 1 mg/ml of ATE was the critical dose, some ATE-positive patients failing to respond to smaller amounts of ATE. Tests with ASE were performed in nine of the 11 ATE-positive patients and were positive in six patients. Again, 1 mg/ml of ASE was the critical dose. The three ATE-positive, ASE-negative patients were not different from other ATE-positive patients in any respect. Only one ATE-negative patient was ASE-positive. All patients, ATE-positive as well as ATE-negative, reacted to at least one of the other recall antigens used. No correlation was seen between ATE sensitivity and sex, age, duration of malignant melanoma symptoms, primary tumor site, regional lymph node involvement, presence of distant metastases, vitiligo or duration of remission. Four ATE-positive patients converted to ATE-negative and two patients converted from ATE-negative to ATE-positive.

4658 DEVELOPMENT OF NEOPLASIA AND KARYOTYPE ANALYSIS IN MICE WITH GRAFT-VERSUS-HOST REACTION. (E.) Hays, E. F. (Ctr. Hlth. Sciences, U. California, Los Angeles). *Cancer Res* 32(2):276-279, 1972.

The effect of graft-versus-host (GVH) reactions on lymphoma development in CBA/H-T6T6 x SJL/J hybrid (TSF₁) mice was studied. Mouse strains used were SJL/J, a strain with a high incidence of reticulum cell sarcoma (RCS); CBA/H-T6T6, a strain with a double marker chromosome; and C3H/HeJ, a strain with a high incidence of mammary carcinoma in females and hepatomas prevalent in males. TSF₁ littermates were injected with 8-30 x 10^6 adult SJL/J spleen cells or with an equivalent amount of cell-free extract of spleen at 8-59 days of age. A 57% mortality rate from acute GVH reactions was found in mice receiving 10, 5, and 3 x 10^6 SJL/J spleen cells at three-week intervals, starting

at 44 days of age. TSF₁ 3- to 7-day-old mice inoculated with $10-20 \times 10^6$ C3H spleen cells showed no GVH reactions. The chromosomes of four TSF₁ mice with acute GVH reactions from RCS were studied; the spleens showed 47 host (marked) and 62 donor (unmasked) metaphases. Aneuploid cells of host origin were found in all tumor-bearing animals but were not present in any animals with acute GVH reactions.

- 4659 VARICELLA-ZOSTER INFECTION IN PATIENTS WITH CANCER. (E.) Schimpff, S. (Baltimore Cancer Res. Ctr., Md.), A. Serpick, B. Stoler, B. Rumack, H. Mellin, J. M. Joseph and J. Block. *Ann Intern Med* 76:241-254, 1972.

Over a 24-month period, among 419 patients with cancer, zoster occurred in 25% of patients with Hodgkin's disease, 8.7% of other lymphoma patients, but in only 1.2% of patients with acute leukemia and 1.8% of patients with solid tumors. A disseminated or generalized form of zoster occurred in 12 of the 37 patients with zoster; these patients were more frequently DNCB-negative, but they were not necessarily receiving continuing cancer chemotherapy. Localization of zoster was frequently related to a site of prior radiation therapy. Recurrence of zoster occurred in eight patients. Patients with advanced Hodgkin's disease, cutaneous anergy, and recent nodal radiotherapy were inordinately predisposed to zoster. Absent varicella-zoster complement fixation titers in exposed patients with lymphoma but not leukemia also predisposed to zoster development. Zoster was an exogenously acquired reinfection in many patients, with a prolonged incubation period. No exposed staff member developed clinical infection, and only two had an antibody rise.

- 4660 RADIOIODINE-LABELED ANTIBODY TEST FOR THE DETECTION OF MEMBRANE ANTIGENS ASSOCIATED WITH EPSTEIN-BARR VIRUS. (E.) Hewetson, J. F., Karolinska Inst., Stockholm, Sweden), B. Gothoskar and G. Klein. *J Nat Cancer Inst* 48(1):87-94, 1972.

A direct, single-label, radioiodinated, antiglobulin technique was used, with viable target cells derived from lymphoblastoid cell lines carrying Epstein-Barr virus (EBV), to detect and measure antibodies against the EBV-determined membrane antigen (MA) complex. The blockings of radioiodinated immunoglobulin binding (RIB) was compared with that of direct membrane immunofluorescence (MIF) for a representative assortment of anti-MA-reactive and control sera. The overall correlation was good between the blocking indices obtained by the two methods (correlation coefficient: 0.76), and the RIB test was approximately four times more sensitive than the MIF test. The RIB test not only gave consistently higher titers but could also detect low concentrations of anti-MA antibodies in certain sera that were negative by the MIF test. Also the RIB test eliminated the laborious reading of the MIF tests.

- 4661 INDUCTION OF RESISTANCE AGAINST EHRlich CARCINOMA BY TUMOR CELLS SENSITIZED WITH IMMUNIZED RABBIT SERUM. (E.) Kato, N. (Fac. Pharm. Sci., U. Tokyo, Japan), S. Ito and D. Mizuno. *Gann* 63(2):173-179, 1972.

Strain ddy mice were injected i.p. with mixtures of Ehrlich ascites carcinoma cells and an anti-Ehrlich carcinoma antiserum prepared in rabbits by inoculation with Ehrlich cells. Injection of Ehrlich cells sensitized with the immune rabbit serum induced resistance to Ehrlich tumor mortality; 80% of mice given sensitized tumor cells survived 30 days post-injection. The survivors were challenged with Ehrlich cells and the LD₅₀ for this challenge was calculated and compared with the LD₅₀ for Ehrlich cells in unimmunized mice. The LD₅₀ for immunized, Ehrlich-resistant survivors was 1.2×10^6 cells/mouse while the LD₅₀ for unimmunized mice was 2.2×10^2 cells/mouse. Survivors of the sensitized Ehrlich cell regimen were also resistant to challenge with sarcoma 180 cells. Similarly, survivors of injections of sarcoma 180 cells sensitized with a sarcoma 180-resistant rabbit antiserum were resistant to challenge with Ehrlich carcinoma cells. Resistant mouse sera prepared from mice surviving sensitized Ehrlich cell regimens were not cytotoxic *in vitro* for Ehrlich cells, but did suppress Ehrlich growth *in vivo*.

- 4662 SELECTIVE SUPPRESSION OF HUMORAL AND CELLULAR IMMUNITY WITH CYTOSINE ARABINOSIDE. (E.) Griswold, D. E. (Roger Williams Gen. Hosp., Providence, R.I.), G. H. Heppner and P. Calabresi. *Cancer Res* 32(2):298-301, 1972.

Tail skin from C57BL mice was grafted onto the backs of C3H/HeJ mice; recipient mice were treated daily with 20 or 40 mg/kg cytosine arabinoside (ara-C) on either days one through five or days six through ten after grafting. Ara-C administered on days one through five did not affect rejection of allografts. Treatment on days six through ten prolonged graft retention by 2.2 days in recipients given 20 mg/kg ara-C and by 4.5 days in recipients given 40 mg/kg ara-C. In C3H/HeJ mice immunized with sheep red blood cells (SRBC), the production of 19S and 7S hemolysin plaque-forming cells (hpfc) in response to SRBC was inhibited by early or late administration of ara-C. However, ara-C administered on days seven through ten after SRBC was less effective in inhibiting hpfc production than ara-C administered on days one through four after immunization. These findings suggest that treatment with ara-C might be valuable in situations in which cell-mediated immune reactions are balanced in opposition to humoral blocking reactions.

- 4663 EVOLUTION OF COMPLEMENT-FIXING ANTIBODY TITERS WITH THE DEVELOPMENT OF BURKITT'S LYMPHOMA. (E.) Sohler, R. (Nat'l. Inst. Hlth. Med. Res., Lyons, France) and G. De-The. *Int J Cancer* 9(3):524-528, 1972.

ra from 29 African Burkitt's lymphoma patients were tested for complement fixing activity (CF) in reactions with a soluble CF antigen from a leukemia-derived, virus-producing lymphoblastoid cell line (IMR-WIL). Burkitt's lymphoma in the patient serum was either in regression or in a controlled state, or the disease was progressing. Patients with controlled or regressing tumors showed relatively low geometric mean titers (GMT) of CF antibody in their sera (mean GMT = 12.35). Patients with progressing tumors showed relatively high CF antibody GMT (mean = 10). In seven of 16 cases, CF antibody titers decreased as tumors regressed; in five of 10 cases CF titers increased as Burkitt's lymphoma progressed.

4 RADIOIMMUNOASSAY OF CARCINOEMBRYONIC ANTIGEN IN EXTRACTS OF HUMAN COLON AND STOMACH. J. Martin, F. (Sch. Med., Dijon, France) and M. S. Stin. *Int J Cancer* 9(3):641-647, 1972.

Carcinoembryonic antigen (CEA) was quantitated by a radioimmunoassay in perchloric extracts of cancerous and noncancerous human colonic and gastric tissues. Sera used in the assay were prepared in rabbits immunized with colonic tumor extracts or purified CEA. CEA content in primary colonic and rectal adenocarcinomas ranged from 8.9-233 mg/g perchloric extract. Liver metastases from large intestinal cancers contained 100 and 228 mg/g CEA, while gastric carcinomas contained less than 0.1-3.0 mg/g CEA. CEA was found in samples of colonic mucosa from noncancerous patients (1.5-8.0 mg/g, but was not seen in extracts of noncancerous gastric mucosa. CEA content in gut extracts from two fetuses was 2.8 and 2.0 mg/g. Comparison of the curves of inhibition of CEA binding to anti-CEA sera obtained using doubling concentrations of purified CEA or perchloric extracts of cancerous colon showed that inhibition was due to antigens with identical immunological reactivities.

5 INCIDENCE OF GROUP-SPECIFIC (gs) ANTIGENS OF TYPE C TUMOR VIRUSES IN SPONTANEOUS NEOPLASMS OF BALB/cCr MICE. (E.) Peters, R. L. (Microbiol. Assoc., Walkersville, Md.), G. J. Spahn, J. Rabstein, H. C. Turner and R. J. Huebner. *J Cancer* 10(2):290-295, 1972.

The incidence of species-specific gs antigen of the type C RNA tumor viruses in the spleen and tumor tissues of BALB/cCr mice with spontaneous neoplasms was determined by the complement fixation (CF) test. The incidence of gs antigen in the diseased spleens of mice with histologically diagnosed leukemia or lymphosarcoma and reticulum cell neoplasms was significantly ($P < 0.05$) higher than that for spleens of age-matched normal animals. Malignancies of CF-positive spleens did not differ histologically. The incidence of gs antigen in spleens of non-neoplastic mice with mammary tumors was the same as in spleens from normal controls. The incidence of gs antigen in the spleens of mice with tumors of mesenchymal or epithelial cell origin (other than mammary) was slightly, but not significantly,

elevated compared with normal controls. A high rate of gs antigen was detected in cell lines derived from both gs-positive and gs-negative donor tumors. Of four gs-negative cell lines, two were from gs negative and two were from gs-positive donor tumors.

4666 THE RESPONSE OF IMMUNOLOGICALLY RECONSTITUTED MICE TO ALLOGENEIC SKIN OR TUMOUR GRAFTS. (E.) Weston, B. J. (Inst. Cancer Res., London, England), C. Cheers, R. L. Carter, E. Leuchars, V. J. Wallis and A. J. S. Davies. *Int J Cancer* 9(1):66-75, 1972.

CBA/H mice were thymectomized two wk before exposure to 850 R X-irradiation; three hr postirradiation, syngeneic bone marrow cells were injected and ten days later allogeneic neonatal thymus lobes were implanted. Immunologically reconstituted mice were given intradermal inocula of EL4 C57BL mouse lymphoma, or skin grafts from syngeneic or C57BL mice. Cytological and histological changes in lymph nodes draining areas of tumor and skin grafts were studied. In mice given lymphoma, lymph nodes increased in wt 6.5 times by 9 to 13 days after inoculation; thereafter, lymph nodes decreased in wt. Smaller increases in lymph node wt were seen after syngeneic or allogeneic skin grafting. Three days after lymphoma inoculation, the lymph node was enlarged and blast cells were prominent. Germinal centers also became active and medullary cords were distended. Paracortical activity subsided 15 days after lymphoma inoculation. In mice given skin grafts, changes in lymph nodes appeared later and were less pronounced than in mice given tumor cells; paracortical hyperplasia first appeared seven days after skin grafting. Total mitotic activity in lymph nodes draining sites of lymphoma grafting increased for seven days after inoculation of tumor cells, and declined after 19 days postinoculation. Peak mitotic response after allogeneic skin grafting was less than after tumor grafting; two mitotic peaks appeared after allogeneic skin grafting, one at 9 days after grafting and the other 15 days after grafting. After the second peak, mitotic activity declined. Seven days after syngeneic skin grafting, there was a burst of mitosis, but this declined by nine days.

4667 IN VIVO ACTIVITY OF IN VITRO IMMUNIZED LYMPHOCYTES: I. TUMOR ALLOGRAFT REJECTION MEDIATED BY IN VITRO ACTIVATED MOUSE THYMOCYTES. (E.) Rouse, B. T. (Walter Eliza Hall Inst. Med. Res., Parkville, Victoria, Australia), H. Wagner and A. W. Harris. *J Immunol* 108(5):1353-1361, 1972.

Thymus cells of cortisone-treated CBA (H-2^k histocompatibility type) mice were cultured with BALB/c (H-2^d) or C57BL (H-2^b) mitomycin-treated spleen cells for six days. The cells were then tested for *in vitro* cytotoxicity by measuring their capacity to cause ⁵¹Cr release from labeled H-2^d and H-2^b tumor

cells. Cytotoxic lymphocytes (CL) generated by thymocytes immunized against H-2^d specifically lysed cells all H-2^d tumors tested when introduced into tumor cell cultures at ratios of 50:1. A mastocytoma cell line was most susceptible to CL lysis; 100% lysis was seen at a CL:mastocytoma cell ratio of 12:1. The *in vitro* lysis caused by CL was immunologically specific; CL immunized against H-2^d cells did not lyse a line of H-2^b thymic lymphoma cells. Tumor growth did not occur in lethally irradiated (800 R) CBA mice injected s.c. with 10⁵ mastocytoma cells and an equal number of CL at the same site. Intravenous injection of CL into lethally irradiated mice given mastocytoma cells s.c. also inhibited tumor growth, but not as efficiently. CL immunized against H-2^d were tested for capacity to protect against various tumors in CBA mice injected i.v. with 10⁶ syngeneic bone marrow cells. Protection was afforded by CL against all tumors of the H-2^d type; mastocytoma cells, which were most susceptible to lysis by CL *in vitro*, were rejected by fewer CL cells than cells of any other tumor. CL protection against tumor inoculation was immunologically specific; H-2^d-immunized thymocytes protected against H-2^d tumor cells at a ratio of 1:1, but did not protect against an H-2^k tumor, even at a ratio of 10:1.

4668 DISSECTION OF THE IMMUNOSUPPRESSIVE EFFECT OF THE Fc REGION OF TUMOR-ENHANCING IgG₂.

(E.) Cruse, J. M. (Dept. Biol., U. Mississippi, University), J. T. Forbes, G. Y. Gillespie, G. K. Lewis, R. W. Scales, B. R. Shivers, J. F. Fields, R. B. Hester, E. S. Watson and H. D. Whitten. *Z. Immunitaetsforsch* 143:43-58, 1972.

C3H_f/He (H-2^k) and TS (H-2^s) mice were immunized against a transplantable fibrosarcoma of C3H_f/He mice by repeated i.p. injections of tumor cells. Half-molecules of tumor-enhancing serum IgG₂ were prepared from antisera from immunized mice by reduction of the critical inter-H-chain disulfide bond using 2-mercaptoethanol and cysteine. Fab and Fc fragments of IgG₂ were obtained by digestive cleavage of IgG₂ with mercuripapain. TS mice were inoculated with half-molecules of tumor-enhancing IgG₂, whole IgG₂, or Fab or Fc fragments of IgG₂. Subsequently, the mice were injected with fibrosarcoma cells. Enhancement of tumor was achieved by Fab and Fc fragments and by whole- and half-molecules of IgG₂. Fc fragments were relatively more effective, and Fab fragments were relatively less effective, than half-molecules of IgG₂ as tumor enhancers.

4669 FURTHER DEFINITION BY CYTOTOXICITY TESTS OF CELL SURFACE ANTIGENS OF HUMAN SARCOMAS IN CULTURE. (E.) Bloom, E. T. (Sloan-Kettering Inst. Cancer Res., New York, N.Y.). *Cancer Res* 32(5):960-967, 1972.

Cells derived from 21 cultures of human sarcoma cells and from nine cultures of normal and neo-

plastic nonsarcomatous cells were reacted in cytotoxicity tests with 115 serum samples from sarcoma patients and nonsarcoma patients. Sera from sarcoma patients were cytotoxic to autochthonous sarcoma cells (the cytotoxicity depended on exogenous rabbit complement). Sarcoma cells were killed by 97% of sera from allogeneic sarcoma patients, 71% of sera from their family members, 80% of sera from patients with nonsarcomatous cancers, and 85% of sera from normal donors. Sera toxic to sarcoma cells were often nontoxic to nonsarcoma cells (including a line of skin fibroblasts from a sarcoma patient). Absorption of some sarcoma patients' sera with autochthonous or allogeneic sarcoma cells decreased cytotoxicity of sera for sarcoma cells, but did not affect their cytotoxicity for nonsarcoma cells. When sera from four patients with osteogenic sarcoma or Ewing's sarcoma were absorbed with the respective allogeneic sarcoma cells and tested for cytotoxicity, it appeared that these sarcoma cells shared at least one antigen, but that Ewing's sarcoma cells had less of this antigen, than did osteogenic sarcoma cells. Different sarcoma cell lines shared antigens which were not shared by nonsarcoma cells. This sensitivity of sarcoma cells to cytotoxic sera varied unpredictably with cell passage. The evidence was that antigens detected in this work were restricted to sarcoma.

4670 GENETIC CONTROL OF THE IMMUNE RESPONSE. THE EFFECT OF THYMECTOMY ON THE PRIMARY AND SECONDARY ANTIBODY RESPONSE OF MICE TO POLY-L (Tyr,Glu)-POLY-D, L-Ala--POLY-L-Lys. (E.)

Mitchell, G. F. (Stanford U. Sch. Med., Stanford, Calif.), F. C. Grumet and H. O. McDevitt. *J Exp Med* 135(1):126-134, 1972.

The effect of thymectomy on the genetically controlled murine immune response-1 (*Ir-1*) to the synthetic polypeptide poly-L(Tyr,Glu)-poly-D,L-Ala-poly-L-Lys [T,G)-A--L] was studied with both aqueous and adjuvant immunization regimens. Adult thymectomy (combined with irradiation and bone marrow transfusion) did not affect the aqueous antigen-induced (IgM) primary response of either high or low responder mice, but did abate the (IgG) secondary or tertiary response, a response which is restricted to the high responder strains. Adult thymectomy also blocked the normal high response to (T,G)-A--L in Freund's adjuvant in high responder mice and the high response to methylated bovine serum albumin (MBSA)-(T,G)-A--L in low responder mice. Neonatal thymectomy was also effective in blocking the response to (T,G)-A--L in Freund's adjuvant in high responder mice. These data are consistent with the concept that the *Ir-1* gene effect is mediated via thymus cell interaction with antigen and with "B"-cells during the time of induction of IgG antibody formation.

4671 ELUTION OF "BLOCKING FACTORS" FROM HUMAN TUMORS, CAPABLE OF ABROGATING TUMOR-CELL DESTRUCTION BY SPECIFICALLY IMMUNE LYMPHOCYTES. (E.)

Ögren, H. O. (Hutchinson Cancer Ctr. Seattle, Wash.), I. Hellström, S. C. Bansal, G. A. Warner and K. E. Hellström. *Int J Cancer* 9(2):274-283, 1972.

Tumor material was obtained surgically from patients with seminoma or osteogenic sarcoma, and from ascites and pleural effusions from patients with endometrial carcinoma, breast carcinoma or ovarian carcinoma. Tumor material was minced and centrifuged, and supernatants were eluted at pH 3.1. High and low molecular wt (MW) fractions (MW = >100,000 and <100,000, resp.) were separated from eluates by ultrafiltration. Low pH eluates were tested for blocking activity of the cytotoxic effect of lymphocytes immune to tumor-associated antigens of the various tumors by an *in vitro* microcytotoxicity assay. Target cells were cells from the tumor employed for elution or cells from other tumors of the same types. Lymphocytes were taken from patients bearing each of the various tumors or from normal donors. Whole unfractionated tumor tissue eluates blocked lymphocyte cytotoxicity. One-to-one mixtures of high and low MW fractions also showed blocking activity. There was no detectable blocking activity when each MW fraction was tested by itself. Blocking was obtained when target tumor cells and lymphocytes were incubated with high MW fractions of tumor eluates and then with low MW fractions but not when the sequence was reversed. The high MW fraction by itself blocked lymphocyte cytotoxicity with ovarian carcinoma target cells. It is concluded that tumor cells growing *in vivo* are coated with blocking factors.

72 IMPAIRMENT OF THE LYMPHOCYTE RESPONSE TO PHYTOHAEMAGGLUTININ IN CHICKENS WITH MAREK'S DISEASE. (E.) Alm, G. V. (Variety Club, S. Ctr., La Rabida-U. Chicago, Ill.), F. J. Accardi and R. D. A. Peterson. *Acta Pathol Microbiol and (A)* 80:109-114, 1972.

Chickens inoculated on the day of hatching with blood from chickens with Marek's disease (MD) were compared with uninoculated birds who developed "contact infection" with MD. Spleen lymphoid cells from both the inoculated and contact-infected chickens were collected and labeled with ^3H -thymidine; the response of the labeled spleen cells to phytohemagglutinin (PHA) was measured by ^3H -thymidine uptake. The PHA response of birds infected with MD by inoculation was significantly impaired compared to normals ($1287 \pm 646\%$ increase in ^3H -thymidine uptake caused by PHA in normal spleen cells vs $435 \pm 581\%$ increase caused by PHA in MD-infected birds' spleen cells). Spleen cells from contact-infected birds showed strikingly reduced PHA-stimulated spleen cell ^3H -thymidine uptake, even when compared to spleen cells of inoculated birds; the latter showed a slight response to PHA, but contact-infected birds showed no positive PHA response. PHA also caused a highly significant inhibition of ^3H -thymidine uptake in gonadal lymphoid cells from birds inoculated with MD.

4673 TUMOR-SPECIFIC RESISTANCE IN MICE DETECTED BY INHIBITION OF MACROPHAGE MIGRATION. (E.) Vaage, J. (U. Texas, M.D. Anderson Hosp. Tumor Inst., Houston), R. D. Jones and B. W. Brown. *Cancer Res* 32(4):680-687, 1972.

Female C3Hf/Bu mice were immunized with s.c. implants of a methylcholanthrene-induced fibrosarcoma or a spontaneous mammary carcinoma. Twenty-five days later the tumor implants were resected and the mice were injected with one of the following: 100,000 and 1,000 g centrifuge supernatants from fibrosarcoma or mammary carcinoma homogenates; irradiation-killed fibrosarcoma or mammary carcinoma cells; starch in NaCl solution; NaCl solution only (control). Macrophage migration in capillary tubes containing peritoneal exudate from presensitized mice given these regimens was observed. Both 100,000 and 1,000 g fibrosarcoma centrifugates strongly and specifically inhibited macrophage motility. Killed fibrosarcoma cells and starch granules showed nonspecific inhibition of macrophage migration. Similar results were found for the mammary carcinoma. Host resistance to fibrosarcomas and mammary carcinomas was also detected by observing the effect of tumor antigens on macrophage spreading on culture dishes. In a related experiment, mice were sensitized against tumors by s.c. implantations of tumor cells one or three wk before challenge tumor inoculation and testing of macrophage migration from peritoneal exudates. Host resistance to challenge as measured by macrophage migration was not fully developed in mice sensitized only one wk before testing.

4674 LYMPHOCYTE CYTOTOXICITY REACTIONS TO LEUKEMIA-ASSOCIATED ANTIGENS IN IDENTICAL TWINS. (E.) Rosenberg, E. B. (Nat'l. Cancer Inst., Bethesda, Md.), R. B. Herberman, P. H. Levine, R. H. Halterman, J. L. McCoy and J. R. Wunderlich. *Int J Cancer* 9(3):648-658, 1972.

The ^{51}Cr -release test was used to examine the cytotoxicity of lymphocytes from relatives and nonrelatives for freshly explanted leukemic blood cells from leukemia patients and for blood target cells from nonleukemic identical twins of these patients. Lymphocytes from nonleukemic twins, parents, siblings and nonrelatives were cytotoxic for target cells of leukemic patients but not for target cells from patients' normal twins in seven twin pairs. Lymphocytes from family members and nonrelatives were not cytotoxic for target cells from either the leukemic or the normal twin in three twin pairs. Allogeneic lymphocytes were cytotoxic for target cells from both the normal and the leukemic twin in four twin pairs. Forty-six percent of lymphocyte tests showed lymphocyte cytotoxicity when lymphocyte donors were older than 20 yr, but only 9% of tests were positive when lymphocyte donors were younger than 16 yr. Positive lymphocyte cytotoxicity reactions to leukemia-associated antigens indicate previous sensitization, which could have resulted from infection with an environmental agent such as a virus.

- 4675 CELLULAR IMMUNITY TO HUMAN BREAST CARCINOMA. (E.) Fossati, G. (Nat. Inst. Study Cure Tumor, Milan, Italy), S. Canevari, G. D. Porta, G. P. Balzarini and U. Veronesi. *Int J Cancer* 10(2):391-396, 1972.

An *in vitro* microassay technique was used to study the cellular immunological response of 16 breast carcinoma patients against tumor-associated antigens. Target cells were obtained from five patients who had pleural effusion due to metastases from breast carcinomas. Lymphocyte suspensions from each of the patients were incubated with either breast carcinoma cells or control cell lines. The lymphocytes obtained from the peripheral blood of three of the five target cell donors had a specific killing effect on autochthonous cancer cells. Lymphocytes from nine of the other 13 cancer patients killed at least one of the target tumor cell lines. Lymphocytes from five of six patients with benign breast lesions, three patients with endometrial, ovarian or colonic cancers, and one female patient without tumor showed no cytotoxic effect on any of the target cells. Negative reactions were obtained with lymphocytes from three of six patients with a localized tumor, but with lymphocytes from only one of ten patients with metastases.

- 4676 IMMUNOLOGIC AND VIROLOGIC STUDIES OF A NON-PRODUCER TUMOR INDUCED BY MURINE SARCOMA VIRUS (HARVEY). (E.) McCoy, J. L. (Natl. Cancer Inst., Bethesda, Md.), R. C. Ting, D. L. Morton and L. W. Law. *J Nat Cancer Inst* 48(2):383-391, 1972.

The growth of PD₄T-1 Harvey murine sarcoma virus (H-MSV)-induced hamster tumors was studied on transplantation of tumor cells to normal adult hamsters and to hamsters immunodepressed by 350 R of X-irradiation. PD₄T-1 was a nonvirus-producing variant cell line derived from the PD₄-MSV(H) cell line, a line which arose from infection of hamster cells with H-MSV and which did produce virus. PD₄T-1 tumor cells grew progressively and killed 14 of 14 irradiated hosts while only five of 12 unirradiated hamsters died from the tumor inoculation. When adult hamsters were given three injections of lethally (15,000 R) irradiated PD₄T-1 cells and challenged s.c. one month later with viable PD₄T-1 cells, significant resistance to tumor cell challenge was seen; 13 of 15 hamsters not preimmunized with tumor cell inocula died from challenge-induced tumors while none of 11 immunized hamsters died. Preimmunized tumor-resistant hamsters were challenged again 43 days after the initial challenge with a ten times larger PD₄T-1 inoculum. Fifteen of 16 nonimmunized, nonresistant hamsters developed progressively growing tumors after this challenge, while tumors grew in only five of 11 preimmunized, resistant hamsters. Preimmunization with producer PD₄-MSV(H) conferred resistance to challenge with PD₄T-1 cells. H-MSV-neutralizing antibodies were not detected in sera of preimmunized PD₄T-1-resistant hamsters, but were seen in sera of hamsters immunized with PD₄-MSV(H).

- 4677 MYELOMA PROTEINS AS TUMOR-SPECIFIC TRANSPLANTATION ANTIGENS. (E.) Lynch, R. G. (Washington U. Sch. Med., St. Louis, Mo.), R. J. Graff, S. Sirisinha, E. S. Simms and H. N. Eisen. *Proc Nat Acad Sci USA* 69(6):1540-1544, 1972.

Female BALB/cAnN mice were immunized with purified myeloma proteins 315 or 460 ten days before challenge with corresponding MOPC-315 and MOPC-460 myeloma tumors. BALB/c mice immunized with proteins 315 and 460 produced antibodies specific for their respective idiotypic determinants. Mice immunized with protein 315 were resistant to challenge with MOPC-315; tumors developed in all unimmunized mice, but in only 11% of protein 315-immunized mice challenged with 5,000 MOPC-315 cells and in 40-60% of immunized mice given 10,000 tumor cells. Immunization with protein 460 conferred resistance to MOPC-460, but this resistance was more difficult to discern than that in the MOPC-315 system. Most of the MOPC-315 tumors which grew in immunized hosts were variants that did not produce protein 315 but rather the light chain of this protein. It is possible that these variants of MOPC-315 grew in immunized mice because the anti-idiotypic immune response selects against myeloma cells that produce the intact myeloma protein and not against cells that produce its light chain only.

- 4678 DELETION OF LIVER-CELL SURFACE MEMBRANE COMPONENTS FROM AMINOAZO-DYE-INDUCED RAT HEPATOMAS. (E.) Baldwin, R. W. (Cancer Res. Campaign Lab., U. Nottingham, England) and D. Graves. *Int J Cancer* 9(1):76-85, 1972.

Cells of a 4-dimethylaminoazobenzene-induced rat hepatoma were reacted in membrane immunofluorescence tests with rabbit antisera prepared against rat liver membrane components. Normal antigens expressed on the surface of rat liver cells were demonstrated when viable liver cells were reacted with the rabbit antiserum. To determine whether individual rat hepatomas showed a loss in antigen normally expressed on liver cells, rabbit anti-liver membrane antiserum was absorbed with hepatoma tissue until it was no longer able to react positively with hepatoma cells. Absorbed serum was then assayed for reactivity against hepatoma and normal liver cells. Absorbed antisera which did not react with hepatoma cells continued to react with normal liver cells, indicating that normal liver-specific cell-surface antigens were deleted in hepatoma cells. In studies with six different hepatomas, antigens deleted from one hepatoma were present in others. This suggested that antigen deletions associated with hepatoma cells result from the replacement of normal liver antigenic components by new tumor-specific antigens.

- 4679 ANTIGENICITY OF L1210 LEUKEMIC SUBLINES INDUCED BY DRUGS. (E.) Nicolin, A. (Natl. Cancer Inst., Bethesda, Md.), S. Vadlamudi and A. Goldin. *Cancer Res* 32(4):653-657, 1972.

Increased antigenicity was manifested by 30 sublines of L1210 ascitic leukemia which were partially or completely resistant to antitumor drugs. Drug-resistant L1210 cells were inoculated into CDF₁ mice. In some cases, mice were given 18 mg/kg 1,3-bis(2-chloroethyl)-1-nitrosourea (BCNU) s.c. six days after inoculation of L1210 cells. The mean survival time (MST) of BCNU-treated and untreated mice given inoculations of drug-resistant L1210 cells was significantly increased relative to the MST of mice inoculated with cells of the original, drug-sensitive L1210 leukemia. Increases in MST of BCNU-treated and untreated mice were reduced if animals were immunosuppressed with cyclophosphamide before inoculation of leukemic cells; the therapeutic effect of BCNU was almost completely reversed in immunosuppressed mice. More direct evidence of increased immunogenicity of drug-resistant L1210 cells was obtained when mice were immunized with X-irradiated drug-sensitive cells or X-irradiated drug-resistant cells. On challenge with viable cells corresponding to those used for immunization, mice were protected more effectively against the drug-resistant challenge cells than against sensitive challenge cells. Sera from mice immunized against drug-resistant L1210 cells demonstrated specific cytotoxic antibodies against the cells of the same drug-resistant leukemia. Animals immunized against the sensitive leukemia cells developed a weak antiserum which did not evidence specific cytotoxic activity.

THE IMMUNOSUPPRESSIVE EFFECTS OF RAUSCHER LEUKEMIA VIRUS (RLV) UPON SPLEEN CELLS CULTURED IN CELL-IMPERMEABLE DIFFUSION CHAMBERS. III. INHIBITION OF RLV-INDUCED CELL PATHWAYS BY ANTIGENIC STIMULATION WITH HEMOCYANIN. (E.) Borella, L. (U. Tennessee Med. Units, Memphis). *J Immunol* 108(1):45-1972.

Spleen cells from normal or Rauscher leukemia virus (RLV)-infected BALB/c mice inoculated with keyhole limpet hemocyanin (KLH) were cultured with or without stimulating doses of KLH in cell-impermeable diffusion chambers that were implanted in irradiated syngeneic mice. Cytomorphologic studies and studies of *in vitro* immunoglobulin synthesis were performed to determine the effects of RLV and KLH on the cells. In uninfected, KLH-restimulated spleen cells in diffusion chambers, a marked transient increase in number of immunoblasts and plasma cells was seen; immunoglobulin synthesis increased markedly in KLH-restimulated spleen cells as compared to KLH-primed spleen cells not restimulated with KLH in diffusion chambers. KLH-restimulated, RLV-infected spleen cells in diffusion chambers also showed increased plasma cell differentiation and increased immunoglobulin synthesis. In RLV-infected spleen cells with KLH, there was an increase in the absolute numbers of blast, myeloid, erythroid and mono-histoid cells (82, 73, 17 and 30 cells/culture $\times 10^4$, resp.). Stimulation with KLH reduced the numbers of blast, myeloid, erythroid and mono-histoid cells to 15, 18, and 11 cells/culture $\times 10^4$, resp. It is postulated that antigenic stimulation of RLV-infected spleen

cells by KLH shifts the differentiation pathway of these stem cells from blast-hematopoietic cells to lymphoid-plasma cells.

4681 LACK OF ANTIGENICITY OF MAMMARY TUMORS INDUCED BY CARCINOGENS IN A NONANTIGENIC PRENEOPLASTIC LESION. (E.) Halpin, Z. T. (Cancer Res. Lab., U. California, Berkeley), J. Vaaga and P. B. Blair. *Cancer Res* 32(10):2197-2200, 1972.

Eight mammary carcinomas were induced by either 3-methylcholanthrene or 7,12-dimethylbenz(a)anthracene in a nonviral- and noncarcinogen-induced preneoplastic (preinvasive) alveolar nodule which had arisen in a hormonally stimulated BALB/c female mouse. The preneoplastic mammary nodule outgrowth was found to be nonantigenic when tested in the strain of origin. Seven of the eight carcinogen-induced carcinomas were also found to exhibit no clear-cut evidence of antigenicity. The eighth tumor, however, was shown to produce tumor-specific immunity in BALB/c mice. The results suggest that carcinogens may not directly induce the appearance of new antigens in the tumors they produce. Furthermore, carcinogens may act in a different manner when inducing a tumor from preexisting preneoplastic lesion.

4682 COMPARATIVE EFFECT OF *MYCOBACTERIUM BOVIS*- AND NEURAMINIDASE-TREATED TUMOR CELLS ON THE GROWTH OF ESTABLISHED METHYLCHOLANTHRENE FIBROSARCOMAS IN SYNGENEIC MICE. (E.) Rios, A. (Dept. Surgery, U. Minnesota, Minneapolis) and R. L. Simmons. *Cancer Res* 32(1):16-21, 1972.

A comparison of the relative efficiency of BCG (*Mycobacterium bovis* strain G) and VCN (*Vibrio cholerae* neuraminidase) treated tumor cells in producing the rejection of established syngeneic fibrosarcomas is presented. C3H/HeJ adult female mice, 8 to 16 weeks old, were inoculated s.c. with 0.5 mg of methylcholanthrene (MCA), dissolved in 0.1% triolein, to produce a fibrosarcoma (MC-42). Sterile tumor cells for inoculation were then prepared from the MC-42 tumors. The basic experimental procedure was to inoculate adult female C3H/HeJ mice with a predetermined number of normal MC-42 tumor cells in suspension, then follow, at various intervals, with a challenge dose of either BCG injected directly into the tumor nodule or s.c. into distant sites from the tumor. A comparative group of cohort mice received injections of 10^6 tumor cells treated with VCN plus mitomycin or of heat-inactivated VCN plus mitomycin. BCG, in doses greater than 0.001 mg, when injected into firmly established MC-42 tumors of C3H/HeJ mice, slowed the growth of the tumors. The greatest inhibition of growth was obtained at a dose of 1 mg BCG/mouse. One injection of VCN-treated tumor cells produced the total regression of one out of ten firmly established MC-42 tumors, and prolonged life to the same degree as did injection of BCG directly into the tumor. Injections of cells with heat-inactivated VCN had no effect on tumor growth. It

was concluded that injection of VCN-treated cells is a more efficient mode of inducing immunity to pre-existing solid tissue tumors than is the introduction of BCG, even if BCG is injected directly into the tumor.

- 4683 AUSTRALIA ANTIGEN IN SINGAPORE CHINESE PATIENTS WITH HEPATOCELLULAR CARCINOMA AND COMPARISON GROUPS: INFLUENCE OF TECHNIQUE SENSITIVITY ON DIFFERENTIAL FREQUENCIES. (E.) Simons, M. J. (World Hlth. Org., Singapore), E. H. Yap, M. Yu and K. Shanmugaratnam. *Int J Cancer* 10(2):320-325, 1972.

Immune adherence hemagglutinin tests (IAHA) were performed on serum from 156 Singapore Chinese with hepatocellular carcinoma (HCC) to determine Australia antigen (Au) in these sera. In electro-osmofusion (EOD) tests, the Au frequency in HCC patients was 1.9%, not significantly higher than in Au frequencies in normal Chinese blood donors. In the more sensitive IAHA tests, HCC patients had Au frequencies of 35.3%, four times higher than normal Au frequencies as determined by IAHA (1.9-7.5%). The relative insensitivity of the EOD test may have accounted for a previous finding of low Au frequencies in Chinese HCC patients. However, the age distribution of patients studied in the previous tests may also have affected results. Younger Chinese HCC patients were shown to have lower Au titers than older patients. There may also be true biological differences between HCC patients in different countries. The Singapore Chinese HCC patients had lower Au titers than Ugandans with HCC.

- 4684 CARCINOEMBRYONIC ANTIGEN (CEA) IN GASTROINTESTINAL AND EXTRAGASTROINTESTINAL TUMORS AND ITS RELATIONSHIP TO TUMOR-CELL DIFFERENTIATION. (E.) Denk, H. (Path. Anat. Inst., U. Vienna, Austria), G. Tappeiner, R. Eckerstorfer and J. H. Holzner. *Int J Cancer* 10(2):262-272, 1972.

Tissue sections from human colonic, gastric, pancreatic, liver, tonsil, bronchial, mammary, ovarian and anal carcinomas were reacted with rabbit anticarcinoembryonic antigen (CEA) sera. The presence of CEA in tumors of different degrees of differentiation was observed by indirect immunofluorescence. In colonic tumors, CEA was found as a rim of specific fluorescence on the tumor cell surface or as cloudy masses in lumina of distended glands. CEA was abundant in well-differentiated colonic carcinomas and less abundant in more anaplastic tumors. Hypersecretory mucoid carcinomas were high in CEA when well-differentiated and low in CEA when poorly differentiated. Well-differentiated colonic carcinoma metastases were high in CEA, poorly differentiated metastases were low. Normal colonic mucosa near tumors, normal mucosa more than 7 cm from tumors, and normal colonic mucosa from tumor-free subjects were negative for CEA. Gastric carcinomas were

less well-differentiated than colonic tumors; well-differentiated gastric tumors had less CEA than comparable colon tumors. Pancreatic tumors contained CEA, but a gastrointestinal lymphosarcoma, a hepatoma, and tonsil, bronchial, mammary, ovarian and anal tumors lacked CEA.

- 4685 CELLULAR REACTIONS AGAINST BURKITT LYMPHOMA CELLS. I. COLONY INHIBITION WITH EFFECTOR CELLS FROM PATIENTS WITH BURKITT'S LYMPHOMA. (E.) Hewetson, J. F. (Karolinska Inst., Stockholm, Sweden), S. H. Golub, G. Klein and S. Singh. *Int J Cancer* 10:142-149, 1972.

Burkitt lymphoma-derived lymphoblastoid cells (line P3HR-1) were used as target cells in tests of colony formation inhibition (CI) with blood leukocytes from Burkitt's lymphoma patients, nasopharyngeal carcinoma patients, and normals (controls) as effector cells. Effector cells were mixed in semi-solid medium with target cells at an effector:target cell ratio of 100:1. Only five of the 62 Burkitt's lymphoma or nasopharyngeal carcinoma effector cells samples inhibited colony formation by more than 30% when compared with normal control cells. However, when effector-target cell mixtures were stimulated by phytohemagglutinin (PHA), almost all effector cell samples caused significant CI. Only six of 31 PHA-treated effector cell samples caused less than 20% CI and 21 showed greater than 40% inhibition. Leukocyte samples which showed high levels of stimulation by PHA were usually active in CI tests, while samples which responded less than one log₁₀ U to PHA inhibited colony formation by less than 40%. Lymph node cells, but not peripheral leukocytes, caused significant CI when tested against autochthonous or allogeneic target cell lines.

- 4686 IN VIVO AND IN VITRO STUDIES OF THE INFLUENCE OF THE IMMUNE STATUS OF C3Hf/Bu MICE ON THE EFFECTIVENESS OF LOCAL IRRADIATION OF A METHYLCHOLANTHRENE-INDUCED FIBROSARCOMA. (E.) Jurin, M. (U. Texas M.D. Anderson Hosp. Tumor Inst., Houston) and H. D. Suit. *Cancer Res* 32(10):2201-2211, 1972.

The influence of the immune status of C3Hf/Bu mice on the effectiveness of local irradiation of a transplanted, methylcholanthrene-induced fibrosarcoma was studied. The numbers of tumor cells that transplanted the tumor into one-half of the recipients were 3.0×10^4 , 2.9×10^2 , and 5.7×10^5 for normal, immunodepressed, or immunized recipients, resp. A tumor reached 12 mm in diameter more quickly when transplanted into immunized recipients than when transplanted into control animals. Also, the radiation dose that controlled one-half of the treated 12-mm tumors was about 1000 rads higher in immunized than in normal recipients. *In vitro* studies showed that lymphoid cells from tumorous mice were effective in inhibiting colony formation

fibrosarcoma cells. The degree of inhibition of colony formation by the lymphocytes decreased according to the size of tumor borne by the lymphocyte donor. Also, lymphocytes collected from tumor-bearing donors were less effective if the donor had been immunized prior to transplantation. The most effective lymphoid cells came from pre-immunized but non-tumor-bearing donors. Serum from tumor-bearing but not from immunized mice contained blocking antibodies, i.e., abolished inhibition of colony growth by lymphoid cells.

7 THE DEVELOPMENT OF SPECIFIC CELLULAR AND HUMORAL IMMUNITY IN MICE INFECTED WITH RAUSCHER LEUKEMIA VIRUS AS NEONATES OR ADULTS.

J. McCoy, J. L. (Bionetics Res. Lab., Bethesda, Md.), A. Fefer, R. C. Ting and J. P. Glynn. *Cancer Res.* 32:1671-1678, 1972.

Neonatal and adult C57BL/6 mice were inoculated with Rauscher leukemia virus (RLV) prepared from splenic homogenates of RLV-infected mice. Mice were given 10^{-1} , 10^{-3} or 10^{-5} dilutions of RLV 1-16 wk before challenge with cells of a Rauscher lymphoma, RBL-3. Adult mice immunized with 10^{-1} RLV were only resistant to RBL-3 challenge as early as 8 wk after immunization. These adults remained resistant for 16 wk. Immunization with smaller dilutions of RLV induced resistance, but only after a 2-16 wk delay. Newborns also developed resistance to RBL-3 challenge after RLV immunization. Resistance appeared 8 wk after immunization (10^{-1} or 10^{-3} dilution of RLV) in newborns and persisted for 12 wk, declining by 16 wk and disappearing by 32 wk. Newborns given 10^{-1} RLV developed primary Rauscher leukemia in 40% of cases; adult mice given RLV did not develop Rauscher disease. Mice given RLV as newborns showed fluorescent tumor antibodies 4 wk postimmunization; the number of newborns with antibodies increased by wk 32, but on transplantation resistance had disappeared. Newborns could resist syngeneic polyoma-induced tumors or grafts even after their resistance to RBL-3 disappeared.

8 TUMOR IMMUNITY IN VITRO: DESTRUCTION OF A MOUSE ASCITES TUMOR THROUGH A CYCLING MECHANISM. (E.) Berke, G. (Duke U. Med. Ctr., Durham, N.C.), K. A. Sullivan and D. B. Amos. *Immunology* 177(4047):433-434, 1972.

Lymphocytes in peritoneal exudates from BALB/c mice injected with EL4 mouse leukemia cells were incubated with ^{51}Cr -labeled EL4 target cells. The effector lymphocytes were extremely effective in destroying the target cells. When EL4 cells were incubated with increasing numbers of effector lymphocytes, it was found that destruction of target cells by lymphocytes depended on the number of lymphocyte-target cell interactions. The effector lymphocytes involved in target cell lysis were not destroyed or inactivated; instead, they recycled and interact with and destroy additional tumor cells.

4689 ISOLATION AND CHARACTERIZATION OF CARCINO-EMBRYONIC ANTIGEN. (E.) Coligan, J. E. (City Hope Natl. Med. Ctr., Duarte, Calif.), J. T. Lautenschleger, M. L. Egan and C. W. Todd. *Immunochimistry* 9:377-386, 1972.

Tumor tissues from 11 human digestive tract tumors, including tumors of the rectum, colon, stomach and liver, were lyophilized and subjected to Sepharose gel and Sephadex gel chromatography. Carcino-embryonic antigen (CEA) was assayed in treated tumor tissues by a radioimmune assay. Individual tumors, even though of the same tissue type, varied greatly in CEA content; one rectal tumor had a final CEA yield of 407 mg/kg, while another rectal tumor had a final yield of 59 mg/kg. CEA was extracted from several tumors by gel filtration on Sephadex G200. The material showed two peaks, one with a sedimentation constant of 10.1S and one with a constant of 6.8S. The latter was the more commonly seen CEA size. The 10.1S CEA could not be converted into 6.8S CEA by dithiothreitol reduction.

4690 SYNTHESIS OF IMMUNOGLOBULINS BY BIOPSIED TISSUES AND CELL LINES FROM BURKITT'S LYMPHOMA. (E.) Further, R. van (U. Hosp., Leiden, Netherlands), H. Gorter, J. J. Nadkarni, E. Klein and P. Clifford. *Immunology* 22:847-857, 1972.

Cell suspensions of Burkitt's lymphomas and 21 cell lines established from the tumors were studied for immunoglobulin synthesis. The capacity of biopsied tissues and cell lines to synthesize immunoglobulin was studied by incubating samples in a medium with radioactive amino acids. Of 50 tumor cell suspensions, 31 synthesized IgG (γ -chains) with type κ and/or λ light chains and five synthesized IgM. Of the cell lines, 12 synthesized IgG (γ -chains); ten of these lines produced type κ light chains and three produced type λ light chains. Three cell lines synthesized μ chains. Neither cell lines nor biopsied tissue material synthesized IgA. Comparison of immunoglobulin synthesis by the biopsied tissues and their derived cell lines showed good agreement in all but three cases. Evidently, immunoglobulin synthesis by cell lines and original tumors showed the same pattern. Observation of cells from biopsies of Burkitt tumors taken at different times and of cells from cell lines showed that the capacity to synthesize particular immunoglobulins and chains remained constant over time.

4691 USE OF THE ^{51}Cr RELEASE TEST TO DEMONSTRATE PATTERNS OF ANTIBODY RESPONSE IN HUMANS TO HERPESVIRUS TYPES 1 AND 2. (E.) Smith, J. W. (Baylor Coll. Med., Houston, Texas), E. Adam, J. L. Melnick and W. E. Rawls. *J Immunol* 109(3):554-564, 1972.

Sera from humans infected with type 1 or type 2 herpesvirus were reacted with herpesvirus-infected,

⁵¹Cr-labeled hamster, rabbit or chick cells and cell cytotoxicity was assayed by the ⁵¹Cr release test. Cytolytic antibodies were evident in all sera in tests with all infected cells. Cytotoxicity by serum from herpesvirus type 1-infected humans was unaffected by absorption of the serum with uninfected cells prior to reaction with ⁵¹Cr-labeled target cells. However, cytotoxicity by this serum was reduced from 85 to 60% by absorption with type 2-infected cells before the ⁵¹Cr release assay and was abolished by absorption with type 1-infected cells. Similar results were seen when anti-type 2 serum was absorbed with uninfected, type 1- or type 2-infected cells. Sucrose gradient separation of sera showed that cytolytic activity resided in the IgM and IgG fractions of sera collected up to 28 days after onset of illness, and in the IgG fraction only of sera collected after 8 months. Cytolytic anti-type 2 antibodies were seen in convalescent sera of patients whose acute sera were negative for type 1 antibody; type 2 antibodies were not removed from these sera by absorption with type 1-infected cells. However, patients with antibodies in acute phase sera had little or no type 2 antibody activity in convalescent sera after absorption with type 2-infected cells.

- 4692 ANTIGENIC CHANGES IN MOUSE EPIDERMIS AT VARIOUS STAGES OF NEOPLASTIC TRANSFORMATION. (E.) Carruthers, C. (Roswell Park Mem. Inst., Buffalo, N.Y.) and M. Bhattacharaya. *Gann* 63(3): 299-305, 1972.

Differences in the urea-extractable antigens in normal epidermis, 3-methylcholanthrene (MC)-induced hyperplastic epidermis, and MC-induced papillomas and skin carcinomas from Ha/ICR mice were investigated in immunodiffusion tests with the urea antigens and immunoglobulins raised against them. Hyperplastic epidermis had antigens distinct from, or present in greater amounts than, those in normal skin. Some antigens, however, were clearly shared by hyperplastic and normal epidermis. There were antigenic differences between normal epidermis, and papillomas and carcinomas. Hyperplastic skin shared some urea antigens with papillomas and carcinomas. Papillomas and carcinomas were evidently identical in urea antigen pattern. Apparently differences develop in the course of neoplastic development in the urea antigen pattern of tissues. Normal tissues develop as quite distinct from papillomas and carcinomas, while hyperplastic tissues are intermediate, sharing some urea antigens with normal tissues and some with neoplastic tissues.

- 4693 ANTIBODY IN SERA OF PULMONARY CANCER PATIENTS AGAINST SPECIFIC SURFACE ANTIGEN OF OAT CELLS. (E.) Oboshi, S. (Nat'l. Cancer Ctr. Res. Inst., Tokyo, Japan), T. Seido and S. Tsugawa. *Gann* 62(6):515-522, 1971.

Search for possible tumor-specific reaction in

human lung cancer was attempted by an indirect membrane immunofluorescence technique. Living cells of the established cell line, OAT, derived from human lung cancer of oat cell type, were used as the target cells and both fluorescein isothiocyanate-conjugated anti-human IgG and IgM goat sera were used as the second reagent. Five out of eight sera from the patients with primary lung cancer of oat cell type gave positive membrane immunofluorescence reaction with anti-IgM reagent but not with anti-IgG. However, 27 sera from the patients with other types of carcinoma, including nine cases of primary adenocarcinoma of the lung, and eight sera from healthy individuals gave no positive reaction. No membrane immunofluorescence reaction was given by the selected positive sera, when they were tested against the cell line of Burkitt lymphoma origin, P3HR-1. These results strongly suggest that antibody against the cell surface of OAT cells resides in the IgM fraction of sera from patients with oat cell carcinoma and that the antigen is specific for and common to oat cell carcinomas of the lung.

- 4694 SUPPRESSION OF GROSS LEUKEMIA CELL-SURFACE ANTIGENS: A KIND OF ANTIGENIC MODULATION. (E.) Aoki, T. (Sloan-Kettering Inst., New York, N.Y.) and P. A. Johnson. *J Nat Cancer Inst* 49(1): 183-192, 1972.

The EoG2 Gross virus-induced leukemia of C57BL/6 mice was transplanted i.p. into C57BL/6 mice immunized with cells of an AKR spontaneous leukemia (K36). Tumor growth rate was measured and the presence of G cell-surface antigens (GCSA) in EoG2 tumor cells was determined by cytotoxicity tests with antisera and tumor cells. EoG2 grew more slowly in immunized than in unimmunized mice. In immunized mice the expression of the GCSA antigen was completely suppressed on EoG2 cells. GCSA reappeared on these cells when they were retransplanted back into unimmunized mice. Other cell surface antigens, including H-2^b, GCSAb and G_{IX}, were not suppressed on EoG2 cells in immunized mice. In electron microscopy studies of transplanted EoG2 leukemias, antibody to GCSA antigen did not affect the budding of Gross virus from tumor cells.

- 4695 POSSIBILITY OF *IN VITRO* ALTERATIONS IN CULTURES OF MAMMARY CARCINOMA CELLS, AND ALTERED IMMUNOLOGICAL RESPONSE IN THE RAT: ACQUIRED CAPACITY TO REJECT INJECTIONS OF MAMMARY CARCINOMA CELLS AND IMPLANTS OF MAMMARY CARCINOMA. (E.) Stone, D. (Worcester State Hosp., Mass.), S. A. Zaccarian and K. Pickering. *Brit J Cancer* 26:315-320, 1972.

Male rats were injected s.c. with 5 x 10⁶ cells from cell cultures of a rat mammary adenocarcinoma; cells were treated *in vitro* before inoculation, as follows: no treatment; treatment with sonicates of cultured hamster cells; treatment with sonicates of autochtho-

nous mammary carcinoma cells; treatment with calf-thymus DNA; treatment with salmon-sperm DNA. Of 25 rats given untreated carcinoma cells, only one (4%) failed to develop mammary carcinoma. Of five rats given calf-thymus DNA- or hamster cell sonicate-treated cells, all developed mammary tumors. Of 12 rats given salmon sperm DNA- or cancer cell sonicate-treated cells, nine (75%) did not develop mammary tumors. Five of these 12 rats (41.7%) showed no carcinoma growth at all after injection of tumor cells and all five developed the ability to reject cultured mammary tumor cell inocula. Four rats from this group could also reject implants obtained directly from mammary carcinoma.

4696 COLD-ANTIBODIES IN RAT SERUM AGAINST YOSHIDA-HEPATOMA ASCITES CELLS. (Ger.) Bayer, R. (Max-Planck Inst. Biochem., Munich, West Germany) and I. von Boehmer. *Z Krebsforsch* 77:40-44, 1972.

Antibodies against Yoshida hepatoma ascites (YA) cells were found in rat serum, which required a cold and a warm phase to produce a cytotoxic reaction. When human complement was added, this reaction took place at 37 C only if the cells were first incubated with antibodies-containing serum at 0 C. A relation between the existence of cold antibodies and ascites transplantation was observed in BDE rats; only one of 44 untreated BDE rats possessed cold antibodies compared with 15 of 25 ascites-bearing BDE rats. In BD VI and Sprague-Dawley rat strains, cold antibodies were found in both treated and untreated rats. Furthermore, cold antibodies also occurred in the serum of 12 of 20 BDE rats that did not manifest tumors after transplantation of YA cells. It is possible that the cold antibodies against YA cells occur after an infection, which, in the case of BDE rats, was stimulated by transplant of fresh YA cells.

4697 SEPARATION OF SKIN REACTIVE INTESTINAL CANCER ANTIGEN FROM THE CARCINOEMBRYONIC ANTIGEN OF GOLD. (E.) Hollinshead, A. C. (George Washington U. Med. Ctr., Washington, D.C.), C. G. McWright, C. C. Alford, D. H. Glew, P. Gold and R. B. Herberman. *Science* 177(4052):887-889, 1972.

Patients with rectal and colonic carcinomas were inoculated i.d. with gel fractions of sonicated cell membranes of allogeneic intestinal tumors or with fetal intestinal cell membrane material. Both membrane preparations produced positive delayed skin hypersensitivity reactions. When tumor and fetal intestinal cell membrane soluble fractions were further fractionated by polyacrylamide gel electrophoresis, the Gold carcinoembryonic antigen (CEA) was found in regions 1 and 2 of the gels. No positive skin reactions were associated with these regions. Another antigen was found in regions 3 and 4. Positive skin reactions were elicited by the proteins in these regions. The results indicate that there are two separable types of human intestinal antigen. Each

is found in fetal extracts and, therefore, can generically be called a carcinoembryonic antigen. The antigen that produces the delayed hypersensitivity reaction presumably has a lower molecular wt than the Gold CEA.

4698 NEWER CONCEPTS OF CANCER OF THE COLON AND RECTUM: CELLULAR IMMUNITY TO HUMAN COLONIC CARCINOMAS. (E.) Hellström, I. (U. Washington Med. Sch., Seattle) and K. E. Hellström. *Dis Colon Rectum* 15(2):100-105, 1972.

Experiments are reported in which human colonic carcinoma cells were cultivated and exposed to peripheral blood lymphocytes of autochthonous or allogeneic patients. Killing of tumor cells by lymphocytes was monitored by a microcytotoxicity assay. Lymphocytes from colon carcinoma patients destroyed colonic tumor cells but did not damage autochthonous normal cells or other types of tumor cell. Lymphocytes from normals and from donors with noncolonic cancer were not cytotoxic. Both autochthonous and allogeneic lymphocytes were cytotoxic. In related experiments, lymphocytes from colonic carcinoma patients destroyed cells from human fetal gut epithelium but did not kill human fetal kidney cells. Although lymphocytes from tumor-bearing subjects can destroy colonic tumor cells *in vitro*, colon tumors do grow progressively *in vivo*. This was attributed to serum factors which block cellular immune cytotoxicity.

4699 THE CATABOLISM OF HUMAN γ G IMMUNOGLOBULINS OF DIFFERENT HEAVY CHAIN SUBCLASSES. III. THE CATABOLISM OF HEAVY CHAIN DISEASE PROTEINS AND OF Fc FRAGMENTS OF MYELOMA PROTEINS. (E.) Spiegelberg, H. L. (Scripps Clin., La Jolla, Calif.) and B. G. Fishkin. *Clin Exp Immunol* 10(4):599-607, 1972.

Fc fragments were isolated from γ G, γ G₃ and γ G₄ human myeloma proteins; H chain disease proteins were also isolated from patients. Proteins were labeled with ¹³¹I or ¹²⁵I and injected into men or monkeys. Catabolic parameters for Fc fragments and H chain proteins were established and compared with the catabolism of intact γ G immunoglobulin. Intact γ G myeloma proteins had significantly different half-lives, while Fc fragments were all eliminated at similar rates. Average plasma half-life of all Fc fragments was 4.3 days. This suggested that structures not present on Fc fragments are responsible for the faster turnover of γ G₃ immunoglobulins and for the different half-lives of myeloma proteins within a given subclass. Plasma half-lives, fractional turnover rates, amounts of protein bound radioactivity excreted in urine and extent of intra- and extra-vascular equilibrium did not differ significantly in any of the three pairs of H chain disease proteins. The fractional turnover rate of these proteins averaged 8% of the intravascular pool/day, as compared to 4% for γ G. One-half to 1% of the intravascular H chain protein pool was excreted into the urine, as compared to 0.1% of γ G.

- 4700 THE DEVELOPMENT OF CELLULAR IMMUNITY TO TUMOR CELLS. (E.) Cerilli, J. (Coll. Med., Ohio State U., Columbus) and M. C. Smith. *Surg Gynecol Obstet* 134(5):739-745, 1972.

CBA mice were sensitized by s.c. and i.p. injections of allogeneic tumor cells (a C3H mammary adenocarcinoma or a DBA methylcholanthrene-induced sarcoma). Ten to 14 days later, mice were challenged with allogeneic tumor cells and the migration of macrophages in peritoneal exudates of the mice was observed. Migration of peritoneal exudate from mice sensitized with allogeneic tumor cells was inhibited. Migration inhibition occurred across both the H-1 and H-2 histocompatibility barriers. When mice were sensitized with isogeneic tumor cells, macrophage migration was inhibited. Migration inhibition by isogeneic tumor cells was specific, e.g., peritoneal cells from DBA mice immunized to the isogeneic sarcoma were inhibited in migration but peritoneal cells from DBA mice immunized with C3H adenocarcinoma were not inhibited. In tests with mice bearing progressively growing tumors, the magnitude of cellular immunity increased linearly with time after challenge with isogeneic tumor cells.

- 4701 PASSIVE IMMUNIZATION AGAINST MURINE LYMPHOMA. (E.) Shirato, E. (M.D. Anderson Hosp., Houston, Tex.), J. G. Sinkovics and E. W. Thornell. *Oncology* 26:80-86, 1972.

Newborn Swiss mice were inoculated i.p. with cells of a virus-induced murine lymphoma displaying the "starry sky" histological pattern (620 cells); some mice were injected with 818 cells, a malignant line derived from 620. Both 818 and 620 cells were lymphoblasts which produced leukemia virus and virus-specific immune globulins. Twelve hr after the inoculation of 620 or 818 cells, mice were injected with rabbit anti-620 or anti-818 sera. Anti-818 serum prolonged survival of lymphoma-bearing mice. Mice given 818 cells and no serum survived for about 18 days, while mice given anti-818 serum and 818 cells survived for 28 days. Anti-620 serum prolonged survival of mice injected with 818 cells to about 21 days. From one mouse, a subline of 818 cells was recovered which had developed resistance to antisera.

- 4702 CELL-BOUND MYELOMA PROTEINS ON THE SURFACE OF MYELOMA CELLS: POTENTIAL TARGETS FOR THE IMMUNE SYSTEM. (E.) Hannestad, K. (Washington U. Sch. Med., St. Louis, Mo.), M.-S. Kao and H. N. Eisen. *Proc Nat Acad Sci USA* 69(8):2295-2299, 1972.

Cells from 11 mouse ascites myelomas were tested for rosette formation when mixed with 2,4,6-trinitrophenylated (Tnp)-sheep erythrocytes; rosette formation was used to demonstrate membrane-bound myeloma proteins (MOPC-315 and MOPC-460) with affinity for Tnp groups. Seventy-nine percent of MOPC-315 tumor cells and 57% of MOPC-460 tumor cells formed rosettes directly with Tnp-erythrocytes. Rosette formation with cells from other tumors required addition of hybrid antibodies

with one site specific for Tnp and the other specific for an appropriate tumor cell surface immunoglobulin. The cellbound immunoglobulin in MOPC-315 and MOPC-460 had the same heavy and light chains, idiotypic determinants and ligand-binding specificities as the respective myeloma proteins secreted by these tumors. A tumor designated MOPC-315-NR was grown from a small proportion of MOPC-315 cells that did not directly form rosettes with Tnp erythrocytes. In Ouchterlony gel diffusion, MOPC-315-NR cells were found to secrete only the light chain of protein 315 and to carry this chain on the cell surface. MOPC-315-NR resembled other tumors in mice challenged with MOPC-315 cells during immune responses to the idiotype of protein 315.

- 4703 HOST IMMUNITY TO A GROWING TRANSPLANTED METHYLCHOLANTHRENE-INDUCED GUINEA PIG SARCOMA. (E.) Cohen, A. M. (Natl. Cancer Inst., Bethesda, Md.), R. C. Millar and A. S. Ketcham. *Cancer Res* 32(11):2421-2426, 1972.

Host immunity to a growing antigenic solid tumor was studied with a transplanted methylcholanthrene-induced sarcoma (MCA-25) in inbred female strain 2 guinea pigs. Tumor-specific cellular immunity was evaluated *in vivo* by delayed cutaneous hypersensitivity reactions to a transplantation antigen extract of the tumor and *in vitro* by splenic lymphocyte-mediated cytotoxicity. Animals receiving 100,000 MCA-25 cells i.m. demonstrated tumor-specific cellular cytotoxicity from seven days to the conclusion of the study 28 days after tumor transplant. Tumors were 10% body weight at this time. MCA-25-bearing animals had a degree of tumor-specific cellular cytotoxicity similar to those of guinea pigs "hyper-immunized" to the MCA-25 antigen. Guinea pigs pre-sensitized to dinitrochlorobenzene developed a delayed cutaneous hypersensitivity reaction to a dinitrochlorobenzene challenge in the presence of a growing MCA-25 tumor. Seven and 14 days after tumor transplant, animals developed a delayed cutaneous hypersensitivity reaction to MCA-25 antigen extract. Animals with tumors larger than 1 cm reacted to dinitrochlorobenzene but minimally to the tumor antigen. To explain the discrepancy between *in vitro* and *in vivo* detectable tumor-specific cellular immunity in animals with tumors larger than 1 cm, the effects of serum from these animals on cellular cytotoxicity were evaluated. Serum from animals with palpable MCA-25 tumors completely inhibited MCA-25-specific cellular cytotoxicity but not cellular cytotoxicity directed against another methylcholanthrene-induced tumor. Studies with serum from animals bearing 1- to 1.5-cm tumors suggested that this inhibition was mediated, at least in part, by antibody directed against the MCA-25 tumor-specific antigen.

- 4704 ANTIBODY AGAINST NEOPLASTIC PLASMA CELLS. II. SUPPRESSIVE EFFECT ON ANTIBODY-PRODUCING CELLS. (E.) Watanabe, T. (Roswell Park Mem. Inst.,

Buffalo, N.Y.), Y. Yagi and D. Pressman. *J Immunol* 107(6):1706-1713, 1971.

Rabbit antisera against five lines of BALB/c mouse myeloma were found to contain antibodies which are specific for surface antigens present on both normal and neoplastic plasma cells. When spleen cells from mice previously immunized with sheep erythrocytes were exposed to the antisera and rabbit complement prior to assay, the formation of hemolytic plaques was strongly suppressed, even though the viability of spleen cells in general was not affected. The suppressive effects of anti-myeloma sera on direct and indirect plaque-forming cells (PFC) were similar in both primary and secondary responses. The suppressive effect was seen with PFC of all nine inbred mouse strains tested. The surface antigens which reacted with the PFC-suppressive antibodies were also present on myeloma cells, but did not appear to be present in significant amounts on lymphocytes of thymus, lymph node and spleen, or on cells of liver and kidney.

705 CLONING OF MOUSE MYELOMA CELLS AND DETECTION OF RARE VARIANTS. (E.) Coffino, P. (Albert Einstein Coll. Med., New York, N.Y.), R. Baumal, Laskov and M. D. Scharff. *J Cell Physiol* 79(3):429-440, 1972.

706 A TRANSIENT LYMPHOTOXIC SERUM FACTOR IN A PATIENT WITH CHRONIC LYMPHOCYTIC LEUKEMIA. (E.) Spengler, G. A. (Dept. Biochem., Case Western Reserve U., Cleveland, Ohio) and R. L. Stjernholm. *N J Med Sci* 263(4):241-252, 1972.

- 80 FOCAL LOSS OF RIBONUCLEASE ACTIVITY IN PRENEOPLASTIC RAT LIVER. (E.) Daoust, (Cancer Inst., Montreal, Quebec, Canada). *Cancer Res* 32(11):2502-2509, 1972.

The distribution of RNase activity in livers of rats fed 4-dimethylaminoazobenzene and of rats fed 3'-methyl-4-dimethylaminoazobenzene was examined by means of an improved substrate film method. The development of liver nodules in these animals was accompanied by a loss of RNase activity. This loss was focal and it preceded the formation of hyperbasophilic foci and hepatomas, which were also RNase negative. The loss of RNase activity occurred earlier in animals fed the highly potent 3'-methyl derivative than in those submitted to the less active azo dye. The results suggest that a deficiency in RNase activity may represent a prerequisite in tumor formation.

- 81 SIMPLE ATROPHIC GASTRITIS AND GASTRIC CARCINOMA. (E.) Walker, I. R. (Royal Melbourne Hosp., Australia), R. G. Strickland, B. Ungar and I. R. Mackay. *Gut (London)* 12(11):906-911, 1971.

Four cases of gastric carcinoma in patients who had atrophic gastritis 9, 10, 18 and 21 yr before diagnosis of cancer are presented. The four cases were derived from long-term observations of 40 atrophic gastritis patients. The four patients included two men, aged 54 and 40 yr, resp., and two women, aged 64 and 57 yr, resp. Tests of vitamin B₁₂ absorption in three patients gave normal results and no gastric autoantibodies were detected in the four patients tested. The gastritis developed by the four patients was multifocal and involved the antrum in three patients; it, therefore, differed from the diffuse gastritis associated with pernicious anemia. Atrophic gastritis without pernicious anemia was concluded to be a more common precursor of gastric carcinoma than atrophic gastritis with pernicious anemia.

- 82 METABOLIC CONTROLS IN PRECANCEROUS LIVER: DEFECTIVE CONTROL OF CHOLESTEROL SYNTHESIS IN RATS FED N-2-FLUORENYLACETAMIDE. (E.) Horton, J. (Waite Agric. Res. Inst., Adelaide, Australia) and J. R. Sabine. *Europ J Cancer* 7(5):459-465, 1971.

Male rats were fed N-2-fluorenylacetamide (FAA) as 0.5% of a basal diet for 2, 3 or 5 wk. Control of cholesterol synthesis during carcinogen treatment was tested by feeding 5% cholesterol for three days, then killing the rats and observing production of ¹⁴C-cholesterol in liver slices treated with 1-¹⁴C-acetate. Liver slices from rats not receiving FAA showed normal control of cholesterol synthesis, while livers of FAA-fed rats showed enhanced cholesterol synthesis with complete loss of feedback control at 3 wk and partial loss at 11 wk. By 16 wk, feedback control was restored in liver but not in hyperplastic nodules present on

some livers at that time. Mean cholesterol synthesis values for FAA-red rat groups were highly variable, ranging from 0.43-1.64% of ¹⁴C recovered from 1-¹⁴C-acetate. Mean values for rats given neither FAA nor cholesterol were 0.22-1.20%, while mean values for rats given cholesterol but no FAA were 0.03-0.10%.

- 4783 AREGENERATIVE ANEMIA WITH HYPERCELLULAR SIDEROBLASTIC MARROW. A PRELEUKEMIC CONDITION. (E.) Reizenstein, P. (Karolinska Hosp., Stockholm, Sweden) and B. Lagerlöf. *Acta Haemat* 47:1-12, 1972.

Twenty-three patients with aregenerative anemia (i.e., anemia with an erythrocyte radio-iron incorporation below 55%) were divided into three groups on the basis of bone marrow morphology: patients with hypocellular, fat-rich marrow (group A); patients with a hypercellular marrow with little fat (group B); and patients with marrow fibrosis (group C). Group A patients had granulocytopenia, but no thrombocytopenia and did not develop leukemia; four of 14 Group B patients died with acute myeloblastic or promyelocytic leukemia; these patients had no granulocytopenia but did have thrombocytopenia and sideroblastosis. Group C patients (three) died with either pancytopenia, leukocytosis or thrombocytosis. Aregenerative anemia with hypercellular marrow and sideroblastosis was considered to be a preleukemic condition.

- 4784 SUBCELLULAR LOCALIZATION OF SURFACE ADENOSINE TRIPHOSPHATASE ACTIVITY IN PRENEOPLASTIC LIVER PARENCHYMA. (E.) Karasaki, S. (Cancer Inst. Montreal, Quebec, Canada). *Cancer Res* 32:1703-1712, 1972.

Male Wistar rats were fed a diet containing 0.06% N,N'-dimethylaminoazobenzene (DAB) for 90 or 180 days. DAB-fed rats were killed and livers were removed and examined (by the Wachstein-Meisel technique) under light and electron microscopes for the presence and distribution of surface adenosine triphosphatase (ATPase). In normal liver parenchyma and in regenerative liver nodules of DAB-fed rats, ATPase reactions were largely confined to bile canaliculi; no ATPase was seen in cell cytoplasm. In contrast, hyperbasophilic foci exhibited ATPase activity over the entire surface of hepatocytes, rather than only at the bile canaliculi. This altered pattern of ATPase was seen even in well-differentiated hepatocytes within the foci. Surface changes of ATPase in hyperbasophilic foci were followed by an increased irregularity of plasma membranes and alterations of other cell organelles, suggestive of dedifferentiation. DAB-induced hepatomas showed cellular atypism and pleomorphism. The entire surfaces of atypical hepatoma cell were usually covered by ATPase reaction products.

- 4785 ELECTRON MICROSCOPIC OBSERVATIONS ON STRUCTURES RELATED TO THE EPITHELIAL BASEMENT MEMBRANE IN SQUAMOUS CELL CARCINOMA. (E.) Frithiof, L. (Karolinska Inst., Stockholm, Sweden). *Acta Otolaryngol (Stockh)* 73:323-334, 1972.

Half-desmosomes, filaments traversing the lamina lucida and aperiodic fibrils were examined in oral epithelium from patients with epithelial hyperplasia, carcinoma *in situ* or suspected invasive carcinoma. Electron microscopy showed that when the basement membrane of cells was absent or atypical, half-desmosomes, traversing filaments and aperiodic fibrils were absent or altered in structure. Observations suggested that the extracellular portions of half-desmosomes originated from the lateral aggregation of the traversing filaments. Half-desmosomes were thought to play a part in the transport of material from basal cells. Aperiodic fibrils were regarded as tropocollagen aggregates. It was concluded that aperiodic fibrils and basement membrane material have a common epithelial origin.

- 4786 BONE MARROW INVOLVEMENT IN BURKITT'S LYMPHOMA: RESULTS OF A PROSPECTIVE STUDY. (E.) Bluming, A. Z. (Uganda Cancer Inst., Kampala), J. L. Ziegler and P. P. Carbone. *Brit J Haemat* 22(3):369-376, 1972.

Bone marrow involvement was studied in 85 previously untreated Burkitt's lymphoma patients. Fourteen patients had bone marrow involvement at some time during the course of their disease (seven of these presented with bone marrow involvement). Bone marrow involvement was generalized; in no case were marrow tumors confined to a single site. Of the 14 patients with bone marrow involvement, only four had tumor cells in peripheral blood; of these four, two had 90% or more circulating tumor cells. Neither sex appeared inordinately prone to bone marrow involvement. The prognosis was slightly worse in patients developing marrow involvement following initial cyclophosphamide treatment than in patients presenting with marrow involvement. Pretreatment bone marrow lymphocytes were 50% higher in patients who later developed bone marrow involvement than in patients who never showed marrow involvement.

- 4787 COMPARATIVE MORPHOGENESIS OF MALIGNANT SKIN MELANOMA. (E.) Blinova, G. A. (Petrov Inst. Oncol., Leningrad, USSR). *Tumori* 57(6):361-371, 1971.

Malignant skin melanomas from 181 female and 95 male patients were examined and classified histologically. The commonest sites of melanomas were the leg in women and the trunk in men. The 276 tumors were divided into those originating from junctional melanoblasts (epidermo-dermal malignant melanomas, or ED type) and those originating from intradermal nevi without involvement of melanoblasts (intra-

dermal malignant skin melanomas or ID type). The ED type was seen more often in legs and feet and the ID type on the trunk. Both types showed rapid as well as slow growth, and there were no clear differences in size, invasiveness or morphological properties between the two types. Lymph node metastasis was more evident in ID than in ED tumors, and ID tumors had a poorer prognosis than ED tumors.

- 4788 PATHOGENESIS OF LYMPHOID NEOPLASIA IN CATS AND ITS RELATIONSHIP TO IMMUNOLOGIC CELL PATHWAYS. I. MORPHOLOGIC ASPECTS. (E.) Mackey, L. J. (U. Glasgow Vet. Sch., Scotland) and W. F. H. Jarrett. *J Nat Cancer Inst* 49(3):853-865, 1972.

Development of lymphoid neoplasia in the cat was studied. Both naturally occurring and experimentally induced neoplasms were examined. They occurred in 4 morbid anatomical distributions: alimentary, multicentric, and thymic lymphosarcoma and leukemia, and in 5 cytologic categories: stem cell, lymphoblastic, prolymphocytic, histiocytic, and lymphohistiocytic. The sites of multiplication and routes of migration through the primary and secondary lymphoid organs were distinct in each morbid anatomic form. In alimentary lymphosarcoma, Peyer's patches and the germinal centers of lymph nodes were initially involved, whereas in multicentric and thymic lymphosarcoma, the early lymph node lesions affected only the paracortical or thymus-dependent areas. In leukemia, the main route was hematogenous, with malignant cells in the bone marrow, red pulp of the spleen, and in the medulla of lymph nodes, as well as the bloodstream. Our results indicate a parallel between the distribution of cells in each form of neoplasia and in different compartments of the immunocyte-producing system. The implications for leukemogenesis are discussed.

- 4789 RELAPSE PATTERNS IN BURKITT'S LYMPHOMA. Ziegler, J. L. (Makerere U. Med. Sch., Kampala, Uganda), A. Z. Bluming, L. Fass and R. H. Morrow, Jr. *Cancer Res* 32:1267-1272, 1972.

The clinical course of 130 patients with histologically confirmed Burkitt's lymphoma seen at the Lymphoma Treatment Center in Kampala, Uganda, was reviewed. Death occurred soon after treatment in 18 (14%), and failure to respond to chemotherapy was observed in five (4%). Of the 107 patients who achieved complete remissions, 84 were followed for at least one yr, or until relapse. Tumor relapse was observed to be of two distinct types. Early relapse was characterized by recurrent tumor growth in the same site as the original tumor and occurred within ten wk of initial therapy. Patients with early relapse tended to have generalized disease on admission, responded poorly to subsequent treatment, and had a poor prognosis. Late relapse occurred more than ten wk after initial therapy and usually appeared in previously uninvolved anatomical sites.

Responses to subsequent chemotherapy were excellent, and the prognosis was good. The pattern of relapse appeared to be independent of the aggressiveness of the initial chemotherapeutic regime. Drug resistance, immunoresistance and/or host immune failure are postulated to explain the emergence of early relapse. Although immunological mechanisms may be operative in the pathogenesis of late relapse, reinduction of tumor remains a possibility.

4790 ANTIGEN-DEFICIENT CELL VARIANTS IN PRENEOPLASTIC FOREIGN BODY REACTION OF MICE.

(E.) Brand, K. G. (Med. Sch., U. Minnesota, Minneapolis), L. C. Buoen and I. Brand. *J Nat Cancer Inst* 49(2):459-465, 1972.

Sarcomas were induced in F₁ hybrids of congenic CBA/Br and CBA/H-T6 or CBA/H mice by s.c. implantation of plastic films. Antigen-deficient variants were derived from 80% of such hybrid tumors by transplantation of multiple tumor pieces to nonhybrid animals of either parent genotype. This percentage was slightly higher than that recorded for chemically induced and spontaneous tumor groups. In another experiment, the implants and surrounding tissue capsules were removed from the hybrid animals during the preneoplastic period 7 1/2 months after implantation. Segments of this material were transferred to nonhybrid animals of either parent genotype. In 60% of preneoplastic transfer experiments, antigen-deficient variant tumors were obtained up to 14 months after transfer. Hybrid origin of the tumors was confirmed on the basis of 16 chromosomes. It is concluded that preneoplastic antigen-deficient variant cells are quite regularly produced in foreign body reactions of mice which, much later, may lead to sarcomas. Quantitative considerations suggest that, in the original hybrid host, preneoplastic variant cells are less competitive than preneoplastic nonvariant cells.

4791 ASPARTATE TRANSCARBAMYLASE CONCENTRATIONS IN RELATION TO GROWTH RATES OF FETAL, ADULT, AND NEOPLASTIC RAT TISSUE. (E.) Herzfeld, A. (Harvard Med. Sch., Boston, Mass.) and W. E. Knox. *Cancer Res* 32:1842-1847, 1972.

Aspartate transcarbamylase activity was assayed in rat tissues and the limitation caused in some tissues by carbamyl phosphate hydrolysis was avoided. Significant activity was found in the particulate cell fractions, especially in fetal and neoplastic tissues, as well as in soluble fractions. The enzyme of the particulate fraction was more sensitive to heat and had greater affinity for aspartate than had the soluble enzyme. Total aspartate transcarbamylase concentrations, relative to the liver standard, were generally higher in fetal tissues and decreased within three weeks after birth to normal adult levels. In the mammary gland, it rose and fell during the lactation cycle in parallel with cellular growth. In transplanted tumors, the relative enzyme concentration was significantly correlated with measured rates of

growth in tumor volume over a 6-fold range of levels and rates. Relative concentrations per g in the faster tumors were similar to those in fetal tissues that grew at similar rates.

4792 TUMORS DEVELOPING FROM *IN VITRO*-TRANSFORMED CELLS IN HOMOLOGOUS AND HETEROLOGOUS ANIMALS. (Rus.) Kuz'mina, S. V. (Inst. Biophys., Moscow, USSR) and L. I. Kalinina. *Vop Onkol* 17(11):59-62, 1971.

A study was made of the tumor-forming activity of four new lines of mouse fibroblasts (MED-14, MED-15, MED-21, and MED-23) when inoculated into mice and hamsters and heterologous recipients. The fibroblasts were cultivated in a mixture of 2/3 Eagle's medium, 1/3 0.5% lactalbumin hydrolyzate, and 10% bovine serum. The fibroblasts were obtained from trypsinized cultures of embryonic fibroblasts of C₃Hf pu II mice by prolonged cultivation *in vitro*. The cells, plain or trypsinized were injected s.c. into 2-30-day-old C₃Hf pu II mice. Some 14- and 30-day-old mice received single s.c. injections of 2.5 mg cortisone acetate 1-2 days before inoculation with fibroblasts. The lines MED-14, MED-15, and MED-23 were contaminated with mycoplasma and were later treated with antibiotics. Syrian hamsters (40), 20 and 30 days old, were injected in both cheek pouches with these fibroblasts. Tumors were morphologically examined immediately and one month after their appearance. All four fibroblast lines produced tumors in C₃Hf pu II mice. Tumors appeared 1-2 days earlier after inoculation of non-trypsinized cells than after trypsin-treated cells. Tumors appeared earlier after inoculation with mycoplasma-free than with mycoplasma-infected cells. In all mice tumors developed early, in the first week after inoculation and, in some cases, were then resorbed. Tumors were sarcomas: mostly spindle-cell and less often polymorphic. In mice given a single s.c. injection of 2.5 mg cortisone acetate, large tumors developed, causing death of the animals. Irreversible large tumors (spindle-cell sarcomas) developed in hamsters which had received MED cells in the cheek pouches. Thus, all cell lines of MED studied showed tumorigenic properties after prolonged *in vitro* cultivation.

4793 ADENOCARCINOMA *IN SITU* OF THE UTERINE CERVIX. (E.) Weisbrot, I. M. (Dept. Path., Norwalk Hosp., Conn.), C. Stabinsky and A. M. Davis. *Cancer* 29(5):1179-1187, 1972.

Case histories of five patients suffering from adenocarcinoma *in situ* (AIS) of the uterine cervix, a rare lesion that may be a precursor of invasive adenocarcinoma, are reported. A starting coincidence with epidermoid carcinoma *in situ* was found. The following observations support the hypothesis that AIS is a precursor of invasive adenocarcinoma: 1) the neoplastic cells line endocervical glands; 2) transitions between benign and malignant epithelium occur in glands retaining a normal or an organoid pattern; 3) individual epithelial cells exhibit pleomorphic changes of carcinoma; 4) the supporting stroma re-

tain a normal relationship to the involved glands; 5) infiltration of stromal connective tissue by minute acini, cell clusters or single file columns was not observed; and 6) none of the cases of AIS treated by complete excision had recurrence of invasive tumor tissue.

- 4794 PATHOGENESIS OF ABELSON-VIRUS-INDUCED MURINE LEUKEMIA. (E.) Siegler, R. (Boston U. Sch. Med., Mass.), S. Zajdel and I. Lane. *J Nat Cancer Inst* 48(1):189-218, 1972.

Neonatal strain Ha/ICR mice injected i.p. with 0.1 ml Abelson virus stock developed a previously unrecognized form of leukemia. The earliest alterations seen in treated mice was retardation or developmental failure of lymph nodes (19 days postinoculation). From 15-20 days postinoculation, 80 of 100 treated mice showed proliferation of undifferentiated stem cells in bone marrow. Proliferating marrow cells spread out from the marrow cavity to invade contiguous structures. Death usually occurred within 30 days postinoculation. C-type virions were seen in tissues of mice inoculated with Abelson virus. Rats given 0.2 ml virus stock within 24 hr of birth developed enlarged (five- to tenfold) cystic lymph nodes and also a severe hemolytic anemia. A mechanism of oncogenesis by Abelson virus which differs from conventional models of viral leukemogenesis is proposed.

- 4795 MULTIPLE PRIMARY TUMOURS IN THE OROPHARYNX AND THE LARYNGOPHARYNX. (E.) Thomas, K. (Northampton Gen. Hosp., England). *J Laryngol Otol* 86(4):327-334, 1972.

4807 DISPOSITION TO LUNG CANCER, AGE AND MONTH OF BIRTH. (Ger.) Danneel, R. (Zool. Inst. U. Bonn, West Germany). *Z Krebsforsch* 76(4):231-235, 1971.

An attempt to link cancer proneness with month of birth in certain age groups is reviewed. The assumption that bronchial carcinoma occurs more frequently in individuals born in February or March is not acceptable on the basis of the data presented. As determined by statistical evaluation of this data, the control groups used for comparison of significance were inadequate. In one case of such attempt at correlation, the control group used was a normal population, and in another case, the control group data were limited to hospital records (cancer cases being omitted) of men aged 50-70 yr. Aside from the unlikelihood of such results being reproducible, it is doubtful that geophysical or cosmic situations in which a man is born could influence his inherited physical and mental constitution to such an extent that they would prevail for the rest of his life. For the individual, such correlations are meaningless, and statistical evidence would have to be based on a very large population.

808 INCIDENCE OF GONADAL CANCER IN THE QUAAHAUG *MERCENARIA MERCENARIA*. (E.) Barry, M. M. Natl. Marine Water Quality Lab., West Kingston, I.I.) and P. P. Yevich. *Oncology* 26:87-96, 1972.

The incidence of gonadal cancers was determined in male and female *M. mercenaria* collected during the summers of 1969 and 1970 in the vicinity of Rose Island Narragansett Bay, Rhode Island. Of 316 females and 223 males studied, 12 females had ovarian tumors and two males had testicular neoplasms. Only one animal (a female) showed evidence of neoplastic cellular invasion which involved the red gland, heart and genital pores. Female and male tumors were histologically the same and were apparently of germ cell origin. Although quahaug neoplasias had several of the characteristics of mammalian germ cell tumors, their lack of lymphocytic infiltration of the connective tissue stroma and the absence of a lobular arrangement of vesicular cells were distinguishing.

809 ANALYSIS OF TRENDS IN AGE-ADJUSTED INCIDENCE RATES FOR 10 MAJOR SITES OF CANCER. (E.) Sullivan, P. D. (Connecticut State Dept. Hlth., Hartford), B. Christine, R. Connelly and H. Barrett. *Am Public Health* 62(8):1065-1071, 1972.

x- and age-specific incidence rates for ten primary cancer sites for 1935-1965 were compared from Connecticut Tumor Registry data. Highly significant increases in incidence of stomach cancer and intestinal cancer were found for both sexes over the 30 yr study period. Stomach cancer and prostate incidence decreased. Lung cancer increased among males more rapidly than other cancers; a significant increase in lung cancer among females was seen for the period 1950-1965. Female

breast cancer increased somewhat, while the incidence of ovarian cancer remained the same during the study period. Uterine cervix cancer remained constant from 1935-1950, then increased significantly between 1950-1965. Uterine corpus cancer incidence rose, probably because cervical cancers formerly registered as "not specified" were later designated as corpus cancer.

4810 RATHKE-POUCH TUMORS IN CHILDREN TREATED AT THE NEUROSURGERY DEPARTMENT OF THE MEDICAL ACADEMY IN KRAKOW. (Pol.) Kunicki, A. (Acad. Med., Cracow, Poland), S. Lechowski, E. Madroszkiewicz and E. Szwagryk. *Neurol Neurochir Pol* 21(5):715-720, 1971.

Clinical manifestation and therapy of 28 children with craniopharyngioma are presented. Five of the children (1 boy, 4 girls) were 0-5 yr; 12 (6 girls, 6 boys) were 6-10 yr; and 11 (4 girls, 7 boys) were 11-14 yr. The most frequent clinical symptoms included headache (85.7%), vomiting (57.2%), impairment of visual acuity (60.7%), impaired growth (50%), obesity (25%), diabetes insipidus (21.5%), drowsiness (17.8%), mental retardation (10.7%), double vision (10.7%) and hemiparesis (3.5%). Endocrine disturbances causing impairment of somatic development, visual disturbances and symptoms of increased intracranial pressure often occurred early in life. Prediagnostically, the most common symptoms were headaches (average duration, 10 months), vomiting (8 months) and impairment of vision (5 months). The most common ocular symptoms were simple atrophy and choked optic disc. Radiologic changes included supra- and intracellar calcification (20 out of 28). Surgery was performed on 27 children: eight are alive 1-9.4 yr later (28%), six died 1-8 yr after surgery, five had recurrence 4-36 months later, six died during the first operation (22%) and four out of five died during the second operation performed because of recurrence.

4811 STATISTICS OF MULTIPLE PRIMARY MALIGNANT NEOPLASMS AND RELATED PROBLEMS. (Jap.) Baba, K. (Keio U. Sch. Med., Tokyo, Japan), Y. Shimosato, S. Watanabe and T. Tajima. *Jap J Cancer Clin* 17(6):424-436, 1971.

Autopsy records for 2104 cases of malignant tumors diagnosed at the National Cancer Research Center (NCC) in Tokyo between May 1962-December 1969 were statistically analyzed for incidence of multiple primary malignant neoplasms. For comparison, records of 486 malignant neoplasms autopsied at Keio University between January 1962-December 1966 were also studied. Frequency of multiple primary malignant neoplasms, including latent, bilateral, single-organ neoplasms or a combination of malignant epithelial and nonepithelial neoplasms, at NCC was 5.4% (111 cases). Excluding bilateral and single-organ primary multiple malignant neoplasms, the frequency was 3.1% (64 cases). The incidence of primary malignant multiple neoplasms, excluding bilateral and single-organ neoplasms, at Keio University Hospital was 2.9%. The annual rate

of increase of frequency of multiple primary malignant neoplasms was 6.8% for Keio University and 10.6% for NCC. These values are higher than the expected frequency calculated according to Warren and Gate's method (1.5%).

- 4812 GEOGRAPHIC DISTRIBUTION OF SKIN CANCER. (E.) Urbach, F. (Temple U. Sch. Med., Philadelphia, Pa.). *J Surg Oncol* 3(3):219-234, 1971.

The role of the ultraviolet radiation of sunlight is presented in relation to the etiology and incidence of skin cancer. A chemical dosimeter system sensitive to UV light was coated on mannequin heads. These in turn were exposed to natural UV light for varying periods. By calculating exposure angles, simulation of a ten-minute exposure representing the month of July at 10 A.M. or 2 P.M. and 8 A.M. or 4 P.M. was achieved. Distribution of sun and sky UV radiation over the irregular surfaces of the mannequin heads was noted. Protection (by shading) of the orbits, upper lip, anterior neck under the chin, retroauricular and nasolabial fold areas was striking. In contrast, tips of ears, nose, scalp, lower posterior neck received maximum amounts of radiation. These findings are important for an understanding of diseases probably due to light (lupus erythematosus, porphyria, polymorphic light eruption and certain types of skin cancer). In additional tests of reflected radiation, grass, water, sand and aluminum foil were used as reflector materials. Grass and water did not significantly affect UV light exposure through reflection. A striking increase was noted in the exposure to radiation by reflection of previously protected head areas when sand and aluminum foil were used as reflector materials. A preliminary study of the distribution by site indicated tendency for squamous cell carcinoma to occur primarily on sites most heavily exposed to UV radiation. In contrast, basal cell carcinomas appeared on areas slightly exposed to UV radiation, indicating that some factor in addition to UV radiation is active in this type of carcinoma. These results demonstrate that anatomical contours have a significant effect on the amount of UV radiation reaching various skin areas. Detailed epidemiologic, meteorologic and biologic studies are presently being carried out on an international basis to develop appropriate prophylactic measures for certain types of cancers related to UV exposure.

- 4813 IMMUNOEPIDEMIOLOGICAL AND *IN VITRO* STUDIES OF POSSIBLE RELATIONSHIPS BETWEEN AUSTRALIA ANTIGEN AND HEPATOCELLULAR CARCINOMA. (E.) Smith, J. A. (Dept. Path., U. Ibadan, Nigeria) and T. I. Francis. *Cancer Res* 32:1713-1720, 1972.

Sera from 50 African hepatocellular carcinoma patients were tested by double diffusion and electrophoresis for Australia antigen (Au(1)) and its antibody for the α -fetoprotein (AF). Sera from control patients with other diseases and liver

tissue from liver cancer patients and controls were also studied. One of the 50 liver cancer patients had Au(1) in serum and two had the Au(1) antibody. Thirty-four liver cancer patients, including the Au(1)-positive carcinoma patient, were AFP positive. The two liver cancer patients with Au(1) antibody were AFP-negative. Liver biopsies of liver cancer patients were negative in direct immunofluorescence tests with anti-Au(1) sera; liver biopsies from some normal blood donors showed positive fluorescence. No control sera showed Au(1). No changes were seen in cultured liver cells treated with Au(1)-positive human sera; cytoplasmic and nuclear Au(1)-associated fluorescence appeared in these cultures 72 hr after initiation. Liver cancer cells treated with Au(1)-positive sera showed cytopathic effects and became nonviable, while serum-treated control liver cell cultures remained viable. No malignant transformation was seen in any liver cell culture. Liver cell cultures treated with 2-acetylaminofluorene and tannic acid showed conversion to an AFP-positive state, a change thought to signalize malignant transformation. Liver cells transplanted into rats continued to produce human AFP in rat sera. Cultured liver cells treated with Au(1)-positive sera had more chromatid breaks in chromosomes than did untreated cultured liver cells.

- 4814 BIAS IN AN AFRICAN CANCER REGISTRY. (E.) Templeton, A. C. (Dept. Path., Makerere U., Kampala, Uganda) and A. Bianchi. *Int J Cancer* 10:186-193, 1972.

Data on cancer incidence throughout Uganda collected since 1952 by the Kampala Cancer Registry were compared with data from Kyadondo County, Uganda, an area where there are many hospitals with reliable records. The comparison indicated that, especially in its early years, the Kampala Registry tended to under-register females, sometimes on the order of two- or three-fold. This bias against female patients was detected by observing increases in female cancer rates in recent years. The age distribution of cancer incidence in all regions of Uganda has remained constant since 1954; there was little correlation between year of study or rate of registration and the proportion of patients over 45 years old. Deep tumors were also formerly underdiagnosed in the Kampala Registry. The biases against female patient registration and against inaccessible tumors have diminished in recent years, probably because of changing social patterns and the increase in hospitals.

- 4815 FAMILIAL OCCURRENCE OF NEOPLASMS OF THE CENTRAL NERVOUS SYSTEM. (Pol.) Bromowicz, J. (Neurosurg. Clin. WAM, Lodz, Poland), H. Araszkiewicz and B. Kinderman. *Neurol Neurochir Pol* 21(5):721-725, 1971.

Two pairs of rare neoplasms (occurring among 1,000 cerebral neoplasms and 200 spinal cord neoplasms treated at a Polish clinic) are described. The first

pair involves two sisters (aged 5 and 10) with optic nerve glioma (astrocytoma), which had caused blindness in their left eyes and severe loss of vision in their right eyes. Head X-rays of both girls showed almost identical changes. The second pair involves a 30-yr-old mother who was operated on with good results for a spinal ependymoma (extra-medullary location at the Th₁-Th₄ level) and her 8-yr-old son who was operated on for astrocytoma of the vermis, which blocked the fourth ventricle. It is stressed that although in the second pair of cases the neoplasms were not identical in structure, they were located in the middle line of the central nervous system.

- 4816 TWO MAJOR HISTOLOGICAL TYPES OF GASTRIC CARCINOMA AMONG THE FIXED POPULATION OF HIROSHIMA AND NAGASAKI. (E.) Yamamoto, T. (Natl. Inst. Hlth., Tokyo, Japan) and H. Kato. *Cann* 62(5):381-387, 1971.

Lauren's histological classification of gastric carcinoma based on the presence of either intestinal or diffuse type was applied to autopsy cases in the fixed population sample of Hiroshima and Nagasaki for 1961-1969. The intestinal type was chiefly seen in older persons and the diffuse type was more frequent in younger persons, especially in women. The ratio of the intestinal type to the diffuse type in Japan was compared with this ratio for high or low risk areas in other countries. The trend of this ratio was similar to that in other cities. There was no statistically significant relation between the occurrence of either type of gastric carcinoma and radiation exposure.

- 4817 EPITHELIOMA OF THE SCROTUM IN SCOTLAND IN 1967. (E.) Doig, A. T. (No affiliation). *Hlth Bull* 28(3):45-51, 1970.

An analysis of 18 definite cases of scrotal epithelioma treated in a hospital in Scotland during 1967 is presented. Two-thirds of the cases were attributed to occupational exposure to oil (9), tar and bitumen (2), and pitch (1). Of the six cases classified as definitely or probably nonoccupational, lack of cleanliness and senility appeared to be the main etiological factors. Clinical aspects, including presence of ulceration or metastasis in glands; treatment; prognosis; and mortality for the individual cases are detailed. Lack of personal cleanliness stemming from inadequate plumbing facilities is seen as an important factor in the incidence of the disease.

- 4818 NASOPHARYNGEAL CARCINOMA IN UGANDA. (E.) Schmauz, R. (Med. Sch., Makerere U., Kampala, Uganda) and A. C. Templeton. *Cancer* 29(3):610-621, 1972.

The histologic features of nasopharyngeal carcinoma in Uganda are outlined. A five-year survey (1964-

1968) of neoplasms seen in the Department of Pathology, Makerere University, Kampala, revealed 90 cases of nasopharyngeal cancer, 83 of which were carcinomas. Histologically, the carcinomas were poorly differentiated and marked by the absence of keratinization and prickly cells. In some tumors, the nuclei were very large, usually round or oval, with a vesicular appearance and prominent nucleoli; these tumors were designated large-cell type. The Regaud type of tumor, in which cells occur in clumps, was quite common. Other tumors were the small-cell type; in these tumors the entire tumor mass was composed of small, often elongated, cells. In many cases histocytes were interspersed with tumor cells giving rise to a starry-sky pattern. Excluding 19 cases from outside Uganda, 44 of the patients with nasopharyngeal cancer were males and 20 were females. The small-cell type of tumor occurred predominantly in older men, and there was a trend toward increasing cancer incidence with age. The nasopharyngeal tumors appeared to be more common and to occur earlier in the northern Nilotic and Para-Nilotic peoples than in the southern Bantu and Sudanic groups. The extent to which these differences are due to hereditary and environmental factors is uncertain.

- 4819 EPIDEMIOLOGY OF LEUKEMIA AND LYMPHOMA IN AN AREA OF THE BUENOS AIRES PROVINCE (1967): COMPARISON WITH THE YEARS 1965-1966. I. LEUKEMIA. (Sp.) Delfor Podesta, L. (No affiliation), E. I. Calcagno, E. Quiroga Micheo and A. Fernandez. *Sangre* 16(1):45-64, 1971.

Mortality from leukemia amounted to 4.04/100,000 (4.66 males and 3.40 females/100,000) in an area covering 19 districts of Buenos Aires Province with an 1.8 million population in 1967. The incidence of leukemia was 3.72/100,000 in nine districts of the same area with a 1.6 million population. The 20-29 years-of-age group appeared to be the least (1.53/100,000) and the above 70 years-of-age group the most (23.67/100,000) affected. Incidence was higher among urban native Argentines than among rural natives, but the overall geographical distribution of leukemia appeared to be more homogeneous than in 1965 and 1966, when the city of Lobos constituted a high-incidence center of acute leukemia. The literature concerned with this is reviewed.

- 4820 NEOPLASMS OF THE CENTRAL NERVOUS SYSTEM. EPIDEMIOLOGIC CONSIDERATIONS. (E.) Percy, A. K. (Mayo Clin., Mayo Fdn., Rochester, Minn.), L. R. Elveback, H. Okazaki and L. T. Kurland. *Neurology (Minneapolis)* 22(1):40-48, 1972.

Mayo Clinic records and ancillary resources were reviewed to determine the incidence of various central nervous system (CNS) neoplasms in the resident population of Rochester, Minnesota, from 1935 through 1968. Of 297 identified cases of intracranial and intraspinal lesions, 174 had primary neoplasms and 123 had metastatic tumors. The 63 primary lesions diagnosed at autopsy included 36 meningiomas, 12 gliomas and 15 neoplasms of other histological types. The remainder

of the primary neoplasms were diagnosed while the patients were living and included 25 meningiomas, 37 gliomas and 48 lesions of other histologic types. The overall ratio of meningiomas to gliomas was 1.2 to 1. The most common primary pituitary tumor was chromophobe adenoma. Schwannomas were the most prevalent spinal cord tumor. The incidence of primary and metastatic neoplasms of the brain increased with age. Meningiomas were twice as prevalent in females as in males. No significant sex difference was noted for astrocytomas or for primary brain and spinal cord tumors. Five-year survival rates for gliomas and meningiomas were 22% and 59%, resp. Investigation of death certificates led to the observation that reliance on them can result in underestimation of the incidence of CNS neoplasms and in confusion or inaccuracy of diagnosis concerning known cases of CNS tumors.

- 4821 EPIDEMIOLOGY OF LEUKEMIA AND LYMPHOMA IN AN AREA OF THE BUENOS AIRES PROVINCE (1967). COMPARISON WITH THE YEARS 1965-1966. II. LYMPHOMA. (Sp.) Delfor Podesta, L. (No affiliation), E. Quiroga Micheo, E. J. Calcagno, S. I. Calabria and N. L. De Olivos. *Sangre* 16(3):258-272, 1971.

The 1967 mortality from lymphoma in 19 districts of Buenos Aires Province, 1.8 million population, amounted to 3.64/100,000; nine districts of the same province with a 1.6 million population had a 3.22/100,000 incidence of lymphoma. Both figures presented a significant increase with respect to 1965 and 1966 data, and Canuelas was considered to constitute a center of high mortality from lymphoma in 1967. Increased incidence was ascertained mainly in lymphosarcoma and Hodgkin's disease among native Argentines. The low frequency in exposure to ionizing radiation or chemical agents in the history of both leukemia and lymphoma patients is pointed out. No evidence for a familial factor in the susceptibility to Hodgkin's disease was found.

- 4822 THE GROSS RATES OF GROWTH OF HUMAN MAMMARY CARCINOMA. (E.) Kusama, S. (Ellis Fischel State Cancer Hosp. Cancer Res. Ctr., Columbia, Mo.), J. S. Spratt, Jr., W. L. Donegan, F. R. Watson and C. Cunningham. *Cancer* 30(2):594-599, 1972.

Among 912 female patients with mammary carcinoma who had radical mastectomy performed at the Ellis Fischel State Cancer Hospital, Columbia, Mo., between 1940 and 1960, two or more gross measurements of the same cancer focus were recorded on different dates for 199. The records of these 199 patients were studied to determine if any relationship existed between the tumor growth rate and the characteristics of the host or the cancer. Tumor growth rates were independent of anatomical site (i.e., breast, lymph node, lung or peritoneum), marital status, race, tumor size, frequency of lymph node metastasis at the time of mastectomy, and frequency

and site of the postoperative metastasis. Tumor volume doubling time did, however, correlate directly with the age of the patient, being faster in patients 21 to 30 yr of age and relatively slow in patients over 60 yr of age. Tumor doubling times tended to be shorter in patients whose preoperative symptoms were of short duration. Prognosis was better for patients with slow-growing tumors, especially those with volume doubling times of greater than eight months.

- 4823 HIGH LUNG CANCER RATES LINKED TO HEARTLAND OF STEEL INDUSTRY. (E.) Cecilioni, V. A. (No affiliation). *Water Pollution Control* 110(8):48-49, 1972.

The death rate due to primary lung cancer was 34 per 100,000 for the years 1966 through 1968 in the industrial steel city of Hamilton, Ontario. A breakdown on the basis of local geography showed that the highest incidence (65 per 100,000) was in the area of the city closest to the main heavy industry section. During the period 1938 to 1968, although the population of Hamilton failed to double, lung cancer deaths increased ten-fold and the iron and steel production increased 15-fold. During this same period, the use of cigarettes and fluorspar (used in steel making) also increased greatly. High airborne fluoride levels were reflected in considerable damage to local vegetation, some of which occurred several miles downwind of the pollution source. Plant life fluoride levels were 20 to 30 times the maximum permissible amount. Fluoride levels in bone samples from six lung cancer victims were three to five times higher than those of noncancer controls. Nearly one-half the cases from the high incidence area of Hamilton were of the oat cell variety, a type which normally is seen in about 20% of primary lung cancers in male smokers.

- 4824 THYMECTOMY AND CANCER--A FOLLOW-UP STUDY. (E.) Vessey, M. P. (Radcliffe Infirmary, Oxford, England) and R. Doll. *Brit J Cancer* 26(1):53-58, 1972.

In an attempt to determine whether adult thymectomy is associated with increased risk for developing neoplastic disease, 423 patients who underwent thymectomy for myasthenia gravis (1942-1964) were identified. Of these, 382 were followed through 1967. A total of five fatal extrathymic tumors was seen in these patients; the expected number of such tumors was 5.5. Three deaths from extrathymic tumors were seen at ages 20-39, while only 0.51 was expected. Five patients developed nonfatal tumors. These results do not suggest that thymectomy in adult life leads to any special risk of cancer, but a more prolonged follow-up of the patients is required before a final conclusion can be drawn.

4840 CHARACTERISTICS OF RNA SYNTHESIS IN ISOLATED CELL NUCLEI OF M-1 SARCOMA AND LIVER OF RATS.

(Rus.) Rubtsova, G. V. (I. M. Sechenov Inst Moscow Med. Inst., USSR), I. I. Votrin and S. S. Debov. *Vop Med Khim* 17(4):415-422, 1971.

DNA functional activity in the RNA-polymerase system of cellular nuclei from primary M-1 sarcoma of rats and nuclei from normal and partially hepatectomized, regenerating liver was studied. Cell nuclei from normal and regenerating liver tissue and tumor liver tissue were homogenized in $MgCl_2$ -containing sucrose solution for study of enzymatic activities. The incubation sample used contained cell nuclei preparation (0.2 ml), nucleosidetriphosphates such as GTP, ATP, and CTP (0.05 ml), C^{14} -uridine triphosphate (0.017 micromole), and tris-HCl buffer (0.2 ml). After incubation, the specimens were frozen, centrifuged for examination of the radioactivity and for isolation of RNA products. RNA polymerase activity, measured by incorporation of C^{14} -uridine monophosphate, was pronounced in all cell nuclei: 43.5 micromicro-mole/mg protein/min in sarcoma M-1, 23.02 in normal liver and 71.9 in regenerating liver. Without ribonucleoside triphosphates, C^{14} -uridine monophosphate incorporation was suppressed in all cell nuclei: 4.3 in sarcoma M-1, 12.0 in normal liver, and 17.6 in regenerating liver. It was also suppressed in all cell nuclei by addition of RNase (500 mcg/ml), DNase (500 mcg/ml) and actinomycin D (60 mcg/ml): 7.4-23.52 micromole/mg protein/min. C^{14} -uridine monophosphate incorporation into RNA nuclei of M-1 sarcoma increased by addition of $(NH_4)_2SO_4$ in the incubation medium as compared to the regenerating nuclei. This indicates that the functional activity of DNA of M-1 sarcoma is lower than that of the regenerating liver. Addition of ammonium sulfate increased the ionic strength of the incubation medium, thereby changing the nucleotide composition of RNA. RNA-polymerase reaction products were studied by a sucrose density gradient method. The sedimentograms of the cell nuclei preparations of the hepatectomized liver showed heterogeneous molecular weights. High-molecular fractions increased with the addition of ammonium sulfate. The sedimentograms of newly-formed RNA of sarcoma were characterized by low-molecular fractions.

4841 TRANSCRIPTIONAL TRANSFORMATION OF WALKER TUMOR CHROMATIN BY NONHISTONE PROTEINS.

(E.) Kostraba, N. C. (Biol. Dept., New York St. U., Buffalo) and T. Y. Wang. *Cancer Res* 32(11): 2348-2352, 1972.

Nonhistone proteins fractionated from normal rat liver and Walker carcinosarcoma can stimulate chromatin-templated RNA synthesis *in vitro*. This was demonstrated using RNA polymerase prepared from rat liver, Walker tumor, or *Micrococcus luteus*. The RNA isolated from these fractionated nonhistone proteins did not activate transcription from chromatin. As judged by DNA-RNA hybridization studies, the altered transcription of chromatin effected by the nonhistone proteins reflects the characteristic transcription from chromatin homologous to the nonhistone proteins.

Thus, when rat liver nonhistone proteins were used to activate transcription from Walker tumor chromatin, the activated transcript was found to contain RNA species similar to that synthesized *in vitro* from rat liver chromatin. Conversely, Walker tumor nonhistone proteins can activate the synthesis of RNA from rat liver chromatin to that partly characteristic of Walker tumor chromatin transcript. It is concluded that the nonhistone proteins are tissue specific in the alteration of transcription of chromatin.

4842 RELATION BETWEEN KARYOTYPE AND CYTOLOGY IN CHRONIC MYELOGENOUS LEUKAEMIA. (E.)

Pedersen, B. (Cancer Res. Inst., Danish Cancer Soc., Radium Ctr., Denmark). *Scand J Haematol* 8(6):494-504, 1971.

A detailed analysis of the karyotype/cytology relationship in 27 patients with chronic myelogenous leukemia is reported. Blood cultures established from patients in all stages of the disease were compared with the cytological character of corresponding peripheral blood samples. Results of these observations indicate that the presence of high numbers of specific chromosomes delays the maturation of granulocyte precursors and leads to the development of hematologic relapse and ultimate blastic crisis. The significant specific observations made in this study are: 1) increasing frequency of hyperdiploid metaphases characterized by supernumerary C members and associated with circulation of more granulocytic precursors; 2) pseudodiploid metaphases with high frequency of small acrocentric chromosomes which were unrelated to the peripheral blood picture; and 3) a different Denver group composition of supernumerary chromosomes.

4843 BLASTIC TRANSFORMATION OF LYMPHOCYTES IN PHA-STIMULATED CULTURES IN CASES OF LYMPHOSARCOMA AND RETICULOSARCOMA AND ITS CLINICAL SIGNIFICANCE. (Pol.) Pluzanska, A. (Acad. Med., Lodz, Poland), E. Polkowska-Kulesza, H. Krauze-Jaworska and E. Krykowski. *Pol Arch Med Wewn* 47(12):685-691, 1971.

Blastic transformation (IB) and mitotic (IM) indexes were determined in 3-day cultures of unstimulated and PHA-stimulated white blood cells obtained from 21 patients (10 mature cell and 6 immature cell lymphosarcoma, 5 reticulosarcoma; 16 previously untreated, 5 tested one month after interruption of therapy) and were compared with those for 20 healthy controls. In unstimulated cultures, the indexes were 0-2% for both patients and controls. In PHA-stimulated patient cultures, the IB varied from 0-63% (mean 19.7%) and the IM from 0-70% (mean 13.1%); in control cultures, IB and IM were 65-81% (mean 71.8%) and 28-90% (mean 51.7%), resp. There was no correlation between extent of disease or histologic type and IB or IM values. Low IB and IM values were seen in all histologic types, but normal or only slightly decreased values were (contrary to reports in the literature) observed most frequently in patients with mature cell lymphosarcoma.

Patients with systemic manifestations and sarcoma cells in peripheral blood had markedly decreased indexes, while those with a mild course and those responding to therapy with remissions had high IB values. It is suggested that IB determination has prognostic value and could also be used in differential diagnosis between lymphosarcoma (in which IB is normal or slightly depressed) and chronic lymphatic leukemia (in which IB is strongly depressed).

4844 THE ROLE OF GLUTAMINE IN THE OXIDATIVE METABOLISM OF MALIGNANT CELLS. (E.) Kovacević, Z. (City of Hope Med. Ctr., Cuerte California), and H. P. Morris. *Cancer Res* 32(2):326-333, 1972.

Experimental evidence is presented indicating a correlation between mitochondrial glutaminase activity and respiration rate of tumor mitochondria in the presence of glutamine. Respiration was studied in purified mitochondrial fractions from homogenates of Morris hepatomas 7316A 7800 and 28A (slow-growing), 5123D (medium-growing), 5123tc and 7777 (fast-growing), MK3 kidney tumor (slow-growing) and Ehrlich ascites cells in Buffalo rats. Oxygen electrode experiments showed that glutamine was a better substrate for mitochondrial respiration than the fast-growing tumors and Ehrlich ascites cells than in the slow-growing hepatomas or normal liver cells. Hepatoma 7777 mitochondria respired at approximately the same rate in the presence of optimal concentrations of glutamine or glutamate (22.0 and 22.5 μ M atoms O_2 /mg/protein/min, resp.), but glutamine K_m for respiration was much lower than glutamate K_m (0.2 mM vs 1.3 mM), indicating a more efficient utilization of glutamine. Normal liver mitochondria respired faster in the presence of glutamate than in the presence of glutamine (37.3 and 23 μ M atoms O_2 /mg/protein/min, resp.), and glutamate K_m for respiration was lower (0.5 mM) than glutamine K_m (11.0). Respiration of malignant tumor mitochondria incubated with pyruvate was always low (e.g., 5.1 μ M atoms O_2 /mg/protein/min in hepatoma 7777) compared with respiration in the presence of glutamine. Pyruvate originating from glycolysis did not inhibit production of labeled CO_2 from ^{14}C -glutamine during incubation of Ehrlich ascites cells. Aerobic oxidation of ^{14}C -glutamine was 1.6- to 2.0-fold greater than that of ^{14}C -glucose in intact Ehrlich ascites cells. Estimates of glutaminase activity in mitochondrial suspensions, based on the rate of conversion of ^{14}C -glutamine to ^{14}C -glutamate and compared with the rate of mitochondrial respiration in the presence of glutamine, revealed that the high enzyme activity and its probable intramitochondrial location were the main factors enabling mitochondrial respiration in the presence of glutamine. Transport of glutamine is not a rate-limiting step in mitochondrial glutaminase activity. Results of mitochondrial swelling experiments showed a correlation between the relative impermeability of the mitochondrial membrane to glutamate and the ability of mitochondria to respire in low concentrations (10-20 μ M) of glutamine. Glutamate accumulated considerably in hepatoma 5123tc and Ehrlich ascites mitochondria during

glutaminase activity in the presence of rotenone. The fact that $NAD(P)^+$ was rapidly reduced by glutamine suggested that this may be one of the factors in the maintenance of the great difference between the oxidation-reduction state of intra- and extra-mitochondrial pyridine nucleotides.

4845 NOTES ON SOME PECULIARITIES OF ENZYMIC PROCESSES IN MALIGNANT TUMOURS AND TISSUES OF THE HOST. (E.) Shapot, V. S. (Acad. Med. Sci., Moscow, USSR), G. I. Vornovitskaya, E. G. Gorozhanskaya, S. Ya. Davidova, A. A. Zhubanova, G. D. Krechetova and I. A. Chudinova. *Neoplasma* 19(4):335-340, 1972.

Unification of the lactate dehydrogenase isoenzyme system (LDH-IS), an indication of biochemical anaplasia, was studied in human leukemias. LDH-IS of myeloid and lymphoid leukemic cells had the same general electrophoretic features as normal granulocytes and lymphocytes, indicating that LDH-IS unification is not an essential property of malignant cells. A comparison of anabolic and catabolic processes in an advanced Zajdela rat hepatoma and in a normal liver showed that the tumor synthesized ribonucleotide precursors of RNA through orotidine-5-phosphate and through uracil (the preferred pathway). When ^{14}C -orotic acid was used as substrate instead of uracil, normal liver converted only one-fifth of it into CO_2 , the bulk being used to synthesize RNA. Apparently, *de novo* synthesis of pyrimidine nucleotides was the main pathway used by normal liver. The impairment of complex enzymic processes by tumors was also studied using a number of different tumor-host systems. The feedback inhibition system controlling cholesterol synthesis in the livers of female rats was found to be impaired in mice with mammary tumors. These findings support the notion that host tissue metabolism comes to resemble tumor tissue metabolism in tumor hosts.

4846 EFFECT OF PREGNANCY, LACTATION AND PITUITARY ISOGRAFTS ON THE GENESIS OF SPONTANEOUS MAMMARY GLAND TUMORS IN THE MOUSE. (E.) Bruni, J. E. (U. Western Ontario Hlth. Sci. Ctr., London, Canada) and D. G. Montemurro. *Cancer Res* 31:1903-1907, 1971.

The incidence of spontaneous mammary tumors was observed in five groups of C3H/HeJ x DBA/2J hybrid female mice: mice given no treatment and force bred to males (group 1); mice given no treatment and remaining virgins (group 2); mice nursing full litters for 25 days (group 3A); mice nursing reduced litters (two or three young) (group 3B); and virgin mice given two intact pituitary isografts under the kidney capsule (group 4). Forced breeding increased mammary tumor incidence (14 of 15 mice in group 1 developed tumors vs 11 of 15 in group 2). Pituitary isografts also caused a significant increase in tumor incidence (14 of 15 mice in group 4). Mice nursing reduced litters and mice nursing full litters did not differ appreciably from force-bred controls or isografted mice in tumor development. Latent periods for tumor development

were longer in groups 2-4 than in group 1. Tumors which developed were adenocarcinomas.

- 4847 STUDIES IN FAMILIAL THYROID CANCER. (E.)
Melvin, K. E. W. (Tufts U. Sch. Med., Boston, Mass.), A. H. Tashjian, Jr. and H. H. Miller. *Trans Assoc Am Physicians* 84(10):144-151, 1971.

An investigation into the hereditary characteristics and biosynthetic activity of medullary carcinoma of the thyroid is reported. Since the hereditary incidence of medullary carcinoma of the thyroid is well established, a study was made of the J family, seven of whom had been diagnosed as having medullary carcinoma. Three of the family members had died of the disease. Sixty-seven adult family members had 4 hr i.v. infusion of calcium gluconate at a dose of 15 ml calcium/kg of body weight. Blood and urine samples were subsequently assayed for their calcitonin and parathyroid hormone content. A control group of 47 normal persons was set up parallel to the test group. Results indicated that all the control group members and 55 test family members presented normal calcitonin and parathyroid hormone levels. Abnormally high levels of both substances were found in 12 of the test group. Of those showing high levels, 11 were surgically treated and tumors were found in all. Total thyroidectomy with removal of lymph nodes was carried out and histologic confirmation of bilateral medullary carcinoma was made. None of the tumors was preoperatively palpable, nor was any evident on radioisotope scan of the thyroid with ^{131}I , ^{99}Tc or ^{95}Se . The calcitonin content of the tumor tissues was counted and showed a 650 to 16,000-fold increase over that found in normal tissue. Genealogy of the family confirmed previously postulated autosomal dominant inheritance of the disease. The first generation progenitor immigrated to the United States in 1901. In the second generation seven of the eight siblings were affected. In the third generation, 11 of 25 offspring of the affected members have confirmed medullary carcinoma of the thyroid. The fourth generation comprising 53 children, who were not included in this study, are expected to have half of their number develop the disease in time. This study will be continued with that group. These results establish a valuable role for radioimmunoassay of serum and urine of calcitonin in high-risk individuals for this disease.

- 4848 GRAWITZ TUMOUR OF THE KIDNEY AND BLOOD GROUPS (PRELIMINARY REPORT). (E.) Uhlir, K. (J. E. Purkyne U., Brno, Czechoslovakia). *Scripta Med* 44(5):273-276, 1971.

A preliminary report on the possible relationship between specific blood groups and the occurrence of Grawitz tumors, the most common of all kidney tumors, is presented. In 219 patients with histologically confirmed Grawitz tumors, the following trend was seen in the blood group analysis: 97 patients had type A blood; 71 had type O; 33 had type B; and 18 had type AB. No specific conclusions were drawn from this

analysis due to the limited number of observations made as related to the total population. However, further investigations appear warranted.

- 4849 EXPRESSION OF DIFFERENTIATED FUNCTIONS IN HEPATOMA CELL HYBRIDS: II. ALDOLASE. (E.) Bertolotti, R. (C.N.R.S., Gif-sur-Yvette, France) and M. C. Weiss. *J Cell Physiol* 79(2):211-223, 1972.

Aldolase assays were performed in the H4IIEC3 rat hepatoma cell line and in four subclones derived from it; aldolase was also assayed in somatic hybrids between 3T3 mouse cells and rat hepatoma cells, and between mouse cells and rat skin cells. Aldolase patterns of H4IIEC3 and one of its subclones showed a strikingly high level of the aldolase A monomer (the ubiquitous glycolytic isozyme) relative to normal rat liver. Hepatoma cells and subclones also synthesized aldolase monomers B (the form characteristic of liver) and C. *In vitro* and *in vivo* passage of hepatoma cells resulted in a reversible modulation of aldolase A activity. All somatic hybrids lacked aldolase B, which was present only in the hepatoma parent. Aldolase A, which was present in cells other than hepatoma cells, appeared in hybrids. The absence of aldolase B in hybrids did not appear due to factors such as species differences, increase in ploidy, inactivation of hepatoma aldolase genes or chromosome loss. Extinction of aldolase B from hybrids more likely reflects a genetic regulatory phenomenon.

- 4850 ACCUMULATING FILAMENTS AND OTHER ULTRASTRUCTURAL ASPECTS OF DECLINING CELL CULTURES DERIVED FROM HUMAN BREAST TUMORS. (E.) Tumilowicz, J. J. (Inst. Med. Res., Camden, N.J.) and N. H. Sarkar. *Exp Molec Path* 16(2):210-221, 1972.

Cells from malignant and benign human breast tumors were observed under the electron microscope during the first, fifth and declining subcultivations. In declining cultures (in which cell replication had effectively ceased), intracytoplasmic filaments 110 Å in diameter were seen in large numbers. In some cells, the cytoplasm was completely occupied by filaments. Filaments were composed of smaller (20 Å diameter) subunits arranged helically with six subunits to one turn of the helix. Declining WI38 cell cultures contained similar 110 Å filaments but in smaller numbers. Budding virus-like particles, resembling the Mason-Pfizer monkey virus, were seen in one of the declining cultures from breast tumors.

- 4851 THE REGULATION OF β -HYDROXY- β -METHYLGLUTARYL COENZYME A REDUCTASE IN MORRIS HEPATOMAS 5123C, 7800, AND 9618A. (E.) Goldfarb, S. (Med. Sch., U. Wisconsin, Madison) and H. C. Pitot. *Cancer*

Res 31:1879-1882, 1971.

β -Hydroxy- β -methylglutaryl coenzyme A reductase was assayed in hepatoma and liver microsomes of Morris hepatoma-bearing and tumor-free rats fed a semisynthetic diet alone or a diet supplemented with cholesterol or cholestyramine under controlled conditions of lighting and feeding. Cholesterol depressed the enzyme activity in hepatoma host livers but not in the hepatomas themselves. Cholestyramine feeding increased the enzyme 4.4- to 10-fold in host livers but had no effect in two hepatomas and caused only a slight elevation of enzyme activity in a third hepatoma. A diurnal rise in enzyme activity, induced by feeding, was seen in host livers and in two hepatomas, but was absent from the third (slowest-growing) hepatoma. This diurnal rhythm and the absence of enzyme regulation in hepatomas after cholesterol or cholestyramine feeding indicate that β -hydroxy- β -methylglutaryl coenzyme A reductase is controlled by at least two different mechanisms.

352 ELONGATED NUCLEAR SHEET AND INTRANUCLEAR MYELIN FIGURE OF HUMAN MEDULLOBLASTOMA.

(E.) Tani, E. (Kyoto U. Med. Sch., Japan), J. Takeuchi, Y. Ishijima, N. Higashi, E. Fujihara, T. Metani and K. Ando. *Cancer Res* 31:2120-2129, 1971.

In sections from medulloblastomas from two patients with tumors in the cerebellum were examined electron microscopically. Nuclei of tumor cells showed two types of changes: cistern-limited nuclear sheets and intranuclear vacuolar profiles and myelin figures. The cistern-limited nuclear sheets were extremely elongated and were enclosed either side by the perinuclear cisterns. They were composed of a central granular or beaded heterochromatin layer between less dense layers, were further limited on either side by the inner nuclear membrane, and ranged from 350-430 Å in width. The central granular layer was continuous with the peripheral beaded layer of nuclear heterochromatin granules. A less dense layer on the nuclear periphery was seen between the inner nuclear membrane and the peripheral heterochromatin layer. The structural association of the inner nuclear membrane and its underlying less dense layer, as well as the peripheral heterochromatin layer, was similar in the cistern-limited nuclear sheet and the nuclear periphery and seemed to form a structural and functional unit. Intranuclear vacuolar profiles and myelin figures were irregular in form and might have been derived from the nuclear membranes by a complicated, irregular invagination. The membranes of the vacuolar profiles and myelin figures showed increased density and thickness and surrounded flocculent substances or islands of cytoplasm; these membranes were not covered by heterochromatin layers. The cistern-limited nuclear sheet and the intranuclear vacuolar profiles and myelin figures may have arisen from different changes in the nuclear membranes of medulloblastoma cells.

4853 ADENYL CYCLASE HORMONE RESPONSES OF CERTAIN HUMAN ENDOCRINE TUMORS. (E.)

Schorr, I. (Dept. Med., U. North Carolina, Chapel Hill), H. T. Hinshaw, M. A. Cooper, D. Mahaffee and R. L. Ney. *J Clin Endocrinol Metab* 34(3):447-451, 1972.

The response of the adenylyl cyclase of human endocrine tumors to hormone stimulation was assayed by observing the conversion of α - 32 P-ATP to 32 P-labeled cyclic AMP. The effect on tissues of sodium fluoride (NaF) was also observed. Adenylyl cyclase in two parathyroid tumors composed mainly of chief cells was increased by 60 and 90% above basal levels by glucagon. Adenylyl cyclase in a third parathyroid tumor was not stimulated by any hormone, but was stimulated by NaF. Adenylyl cyclase in a thyroid follicular adenoma was markedly stimulated by thyroid stimulating hormone, luteinizing hormone and NaF. Adenylyl cyclase in a chromophobe adenoma was increased twofold by ACTH. Pheochromocytomas from two patients were not stimulated by any hormone tested. Each of the bilateral pheochromocytomas from a third patient, however, was stimulated by ACTH and by thyroid stimulating hormone.

4854 KINETICS OF 3 H-5 α -DIHYDROTESTOSTERONE METABOLISM IN NORMAL MEN AND WOMEN AND MEN WITH PROSTATIC CARCINOMA: EFFECTS OF ESTROGEN ADMINISTRATION IN MEN. (E.) Bird, C. E. (Dept. Med., Queen's U., Kingston, Ontario, Canada) and A. F. Clark. *J Clin Endocrinol Metab* 34(3):467-472, 1972.

Metabolic clearance rates, transport and metabolic rate constants and distribution volumes for plasma 3 H-5 α -dihydrotestosterone (5 α -DHT) in nine normal males, four normal females and four men with prostate carcinoma were established. Subjects were given a single injection of 5 α -DHT. Metabolic clearance rates (expressed as liters (L)/24 hr) were significantly lower in prostate carcinoma patients than in normals, and were also lower in normal women than in normal men. Volumes of 5 α -DHT distribution were significantly smaller in patients than in normals. The rate constants for 5 α -DHT metabolism were similar in the three groups of subjects. These 5 α -DHT metabolic parameters in four older men with prostate carcinoma observed before gonadectomy or other therapy were similar to the same parameters in normal men. Oral estrogen therapy for these men decreased metabolic clearance rate values and distribution volume values. Similar changes were seen when oral estrogen was given to normal young men.

4855 CHANGING PATTERNS OF BREAST CANCER. (E.) Cady, B. (Lahey Clin. Fdn., Boston, Mass.). *Arch Surg (Chicago)* 104(3):266-269, 1972.

Pathologic findings (1929-1968) from 3,426 patients with primary operable breast cancer were analyzed

for the maximum diameter of the primary cancer and the number of metastatic axillary lymph nodes. Statistically significant trends toward progressively smaller primary cancers and fewer axillary metastases were noted, particularly over the 20 years ending in 1968. Based on 1968 records, the median maximum diameter of primary breast cancer is now 2.5 cm and the mean maximum diameter is 3.07 cm. Fifty-three percent of operative specimens now have negative axillary lymph nodes, 31% have one metastatic node, 14% have two metastatic nodes and 13% have three metastatic nodes. The changing patterns are assumed to be the result of increased public awareness of the implications of breast masses.

- 4856 COMPARATIVE STUDIES ON THE *IN VITRO* AND *IN VIVO* MORPHOLOGY OF CLONES OF EXPERIMENTAL CNS TUMOURS IN THE RAT. (E.) Thust, R. (Med. Acad., Erfurt, East Germany) and R. Warzok. *Acta Neuropath* 20:248-257, 1972.

Fourteen clones were established from two rat central nervous system sarcomas, one induced by N-nitroso-methylurea and one by ethylnitrosourea. In general, the clones showed high cell density but no complete monolayers; cells piled up to form a honeycomb pattern. Cloned cells injected into rats *in vivo*, produced spindle-shaped sarcomas with a characteristic orientation around the blood vessels. It was not clear whether these tumors were true sarcomas or dedifferentiated glial tumors. The *in vitro* morphology of clonal tumor cells differed from their *in vivo* morphology.

- 4857 METABOLISM OF HEPATOMAS OF DIFFERENT GROWTH RATES *IN SITU* AND DURING ISCHEMIA. (E.) Weber, G. (Indiana U. Sch. Med., Indianapolis), M. Stubbs and H. P. Morris. *Cancer Res* 31:2177-2183, 1971.

Tissue samples were taken from regenerating rat liver and from three Morris hepatomas and assayed spectrophotometrically for fifteen metabolites. Tissue samples were taken initially and again during ischemia up to ten minutes after the initial samples. In Morris hepatomas 5123-D (slow-growing) and 3924-A (fast growing), levels of ATP, total adenine nucleotides and the ATP/ADP ratio were markedly lower than those in livers. During ischemia in liver and in 5123-D and 9618-A (also slow-growing), ATP, total adenine nucleotides and the ATP/ADP ratio decreased while AMP levels increased. In hepatoma 3924-A, ischemia did not change ATP or AMP concentrations. Glucose and pyruvate concentrations were 11-43% lower in all hepatomas than in liver. During ischemia, glucose levels increased in liver and in 9618-A. Initial lactate and glutamate concentrations were much higher in 3924-A than in liver or in the slow-growing hepatomas. 2-Oxoglutarate concentrations were low in all tumors. Acetyl-CoA, acyl-CoA, total glycerides, phospholipids and total lipids in

3924-A were 20-50% of liver values. In ischemia, acyl-CoA concentrations increased in liver but did not change in tumors. Acetyl-CoA, glyceride, phospholipid and total lipid content did not change either in liver or in 3924-A. Acetoacetate in liver increased five- to six-fold during starvation and 13-20-fold in hepatomas.

- 4858 INCREASED ANDROGENIC ACTIVITY AS AN ETIOLOGIC FACTOR IN HUMAN BREAST CANCER. (It.) Grattarola, R. (Natl. Inst. Tumor Studies and Ther., Milan, Italy). *Tumori* 57(4):279-285, 1971.

Urinary steroids were determined in 15 premenopausal 30 to 53-year-old women and in seven postmenopausal 55 to 72-year-old women 3 to 6 months after breast cancer mastectomy and compared with those of age-related healthy subjects. A single 24 hr urine sample was collected on the 22-23rd day of the menstrual cycle in the younger group and an endometrial biopsy was performed subsequently. The controls had an ovulatory cycle according to the excreted pregnanediol levels (2.03 mg/24 hr) and to the progestational features of the premenstrual endometrium; testosterone excretion ranged from 2.5 to 22.7 μ g/24 hr. Of the 15 premenopausal patients, seven had an ovulatory cycle with a progestational premenstrual endometrium, and testosterone excretion from 7.5 to 35.0 μ g/24 hr. The other eight patients had an anovular cycle and presented an atypical hyperplastic structure of the premenstrual endometrium with urinary testosterone levels from 36 to 113 μ g/24 hr. No significant differences in estrogen excretion were ascertained among these three groups. In the third group, three patients with the highest androgenous activities (67, 88, and 100 μ g testosterone excretion per 24 hr) had advanced hyperplasia of the interstitial cells of the ovaries as observed upon bilateral surgery. Three other patients in the same group, who received no treatment after mastectomy, developed lung metastases 6 months after this investigation. The average urinary testosterone was 9.4 μ g and 35.6 μ g/24 hr in the postmenopausal control and mastectomized patient groups, resp. Hypotrophic endometrium was found in patients with the lowest testosterone excretion levels (12 μ g/24 hr), while hyperplastic features were observed in the biopsy samples of endometrium from patients with urinary testosterone from 40 to 75 μ g/24 hr. Since the highest testosterone excretion levels occurred in breast cancer patients with anovular menstrual cycle and hyperplastic endometrium, androgenous activity is viewed as a possible factor in the etiology of mammary gland cancer.

- 4859 STUDIES ON BRANCHED CHAIN AMINO ACIDS TRANSAMINASE ISOZYMES IN VARIOUS CANCER CELLS AND ONCOGENESIS. (Jap.) Ogawa, K. (Tokushima U., Sch. Med. Japan). *J Jap Biochem Soc* 43(4):197-209, 1971.

This study was conducted to examine the transformation

of the branched chain amino acid transaminase isozyme pattern caused by cancerous growth. The Yoshida ascites liver cancer AH 130 showed a different isozyme pattern (I plus III) from the mother cell, presumably the liver of a rat, which had the isozyme pattern I plus II. The new type isozyme contained in the new tumor cell was extremely similar as far as its biochemical and immunologic properties are concerned to type III enzyme which exists in the brain of a normal rat. Its immunologic properties are completely different from type I enzyme within the same cell. The formation of type III isozyme and the disappearance of type II isozyme was repeated not only in AH 130 but in other Yoshida ascites liver cancers and Yoshida tumors. Type III isozyme was found in some Morris mutation liver cancers; also, an isozyme pattern midway between a normal liver and the Yoshida ascites liver cancer was recognized in the Morris cancer. There is a correlation between the formation of type III isozyme and the proliferation rate of the Morris mutation liver cancer. A mixed type of liver cancer and cholangioma was induced by administering a synthetic diet containing 0.06% of 1-methyl-4-dimethylaminoazobenzene to normal rats. In all cases except one, type III isozyme occurred, and type II isozyme disappeared where type III appeared. However, noncancerous cells still showed I plus II isozyme pattern, and III was not recognized in them.

285-290, 1972.

Phenylalanine ammonia-lyase effectively inhibited DNA synthesis in leukocytes from five patients with acute lymphoblastic leukemia and caused a rapid cessation of cell growth in murine L5178Y lymphoblasts, with eventual loss of cell viability and concomitant cell death. Addition of 0.125 and 0.250 units of the enzyme to the human leukemic lymphocytes inhibited DNA synthesis by 60 and 80%, resp. Approximately 3.25 units were required for rapid cessation of growth in the murine lymphoblasts; however, lower concentrations (0.5-3.0 units) also prevented subsequent cell growth. Phenylalanine ammonia-lyase was as effective as asparaginase in inhibiting DNA synthesis in leukemic cells. Pretreatment of nondividing normal lymphocytes with phenylalanine ammonia-lyase had essentially no effect on DNA synthesis resulting from subsequent PHA stimulation; but treatment of normal dividing cells after PHA addition caused delayed onset of DNA synthesis and marked inhibition. Neither cinnamic acid, coumaric acid and ammonia, the products of phenylalanine and tyrosine deamination, nor inactivated phenylalanine ammonia-lyase affected lymphoblast growth. These results suggest that phenylalanine ammonia-lyase exerted its effects by depriving leukemic lymphocytes of phenylalanine and tyrosine.

860 ENZYME-SUBSTRATE COMPLEXES OF ATP-SULFURYLASE FROM MOUSE MASTOCYTOMA. (E.) Shoyab, M. U. Southern California, Sch. Med., Los Angeles) and Marx. *Biochim Biophys Acta* 258(1):125-132, 1972.

ATP-sulfurylase (ATP:sulfate adenylyltransferase, EC 2.7.7.4) was purified from Furth mouse mastocytoma. ATP-enzyme complex was isolated from an ATP-enzyme incubation mixture by Sephadex G-75 elution. Experiments using γ - ^{32}P labeled ATP-enzyme complex incubated in the presence of Na_2SO_4 indicated that sulfate replaced the γ phosphate of ATP. Incubation of unbound enzyme with $\text{Na}_2^{35}\text{SO}_4$ did not result in formation of ^{32}S -enzyme, but in the presence of ATP, the reaction yielded radioactive sulfate bound by ATP-sulfurylase. It was concluded that enzyme-bound ATP reacted with sulfate to form adenylyl sulfate (APS) with release of pyrophosphate. An exogenous divalent cation was necessary for conversion of ATP-enzyme to APS. Pyrophosphate inhibited conversion of ATP-enzyme to APS, possibly by reacting with APS to produce ATP and SO_4^{2-} . Incubation of $[\text{S}^{35}]\text{APS}$ and yeast APS kinase in the presence of ATP and Mg^{+2} resulted in a 100% yield of enzyme-bound $[\text{S}^{35}]\text{3'-phosphoadenylylsulfate (PAPS)}$, which was then released from the enzyme. Based on experimental evidence, a reaction sequence is proposed involving ATP-sulfurylase-ATP and ATP-sulfurylase-adenylylsulfate complexes as intermediates.

4862 INCREASED ACTIVITY OF TRANSFER RNA N^2 -GUANINE DIMETHYLASE IN TUMORS OF LIVER AND KIDNEY. (E.) Craddock, V. M. (Med. Res. Council Labs., Carshalton, Surrey, England). *Biochim Biophys Acta* 272(2):288-296, 1972.

The methylation of *E. coli* tRNA by enzyme extracts prepared from normal tissue and from dimethyl- and diethylnitrosamine-induced tumors from albino Porton strain rat liver and kidney was studied using S-adenosyl($\text{Me-}^{14}\text{C}$) methionine as methyl donor. The *in vitro* assay methylated tRNA product was hydrolyzed and analyzed on a Dowex 50-X12 column with 7-methylguanine as a reference. Normal tissue extracts methylated N^2 -methylguanine to a limiting extent, indicating saturation kinetics, whereas tumor extracts showed an increased extent of tRNA N^2 -methylguanine methylation which was not saturable. Extracts from dimethyl- or diethylnitrosamine-"damaged" livers, from thioacetamide-treated nodular livers, and from normal regenerating liver showed methylase activities similar to that of normal rat liver. The relative increase of N^2 -dimethylguanine formation in liver and kidney tumors appeared to be related to the malignant state or to cellular differentiation. Evidence suggested that the increased N^2 -guanine dimethylase activity in tumor tissues was possibly due to loss of a nondialyzable inhibitor of the enzyme.

861 THE EFFECTS OF PHENYLALANINE AMMONIA-LYASE ON LEUKEMIC LYMPHOCYTES *IN VITRO*. (E.) Bell, C. W. (U. Oklahoma Med. Ctr., Oklahoma City), J. Stith and D. S. Hodgins. *Cancer Res* 32(2):

4863 INCREASED TOLERANCE OF LEUKEMIC MICE TO ARABINOSYL CYTOSINE WITH SCHEDULE ADJUSTED TO CIRCADIAN SYSTEM. (E.) Haus, E. (St. Paul-Ramsey Hosp., St. Paul, Minn.), F. Halberg, L. E.

Scheving, J. E. Pauly, S. Cardoso, J. F. W. Kuhl, R. B. Sothorn, R. N. Shiotsuka and D. S. Hwang. *Science* 177(4043):80-82, 1972.

Male BDF₁ mice were kept in light-controlled environments before being injected i.p. with L1210 mouse leukemia cells. About two days after injection, mice were put on one of two courses of leukemia chemotherapy with arabinosyl cytosine (ara-C). One group was given eight i.p. doses of ara-C at 3 hr intervals over a 24 hr period (total dose = 240 mg/kg/day) at four day intervals. Another group of mice was given ara-C in sinusoidally increasing and decreasing 24 hr courses, the largest doses being given at previously determined circadian and circannual times of peak host resistance to ara-C. The early mortality of L1210-inoculated, ara-C-treated mice was due to drug toxicity; none of the mice showed gross evidence of leukemia at autopsy. Ara-C treatment adjusted for periodicity significantly improved tolerance to ara-C in leukemic mice as determined by survival times. The survival time for mice given the adjusted ara-C regimen was 28.4 days (mean), while that for mice given the standard unchanging ara-C regimen was 15.0 days (mean).

4864 ISOLATION OF TUMOR CELL SURFACE BINDING SITES FOR CONCAVALIN A AND WHEAT GERM AGGLUTININ. (E.) Wray, V. P. (Grad. Sch. Biomed. Sci., U. Texas, Houston) and E. F. Walborg, Jr. *Cancer Res* 31:2072-2079, 1971.

Previous results had shown that a sialoglycopeptide-containing fraction released by papain digestion of Novikoff ascites tumor cells could inhibit the agglutination of ascites tumor cells by concanavalin A (con A) and wheat germ agglutinin (WGA). The present report describes a procedure for the resolution of this glycopeptide fraction into its components and the characterization of each of these components with respect to inhibition of cell agglutination by con A and WGA. The original sialoglycopeptide fraction was further digested with pronase and was then submitted to gel filtration on Sephadex G-50 and finally to ion-exchange chromatography on DEAE-cellulose. The glycopeptides were resolved by gel filtration into a low (mw = 2000-3300) and a high (mw >3300) molecular wt fraction. The low molecular wt fraction was separated on DEAE-cellulose into five sialoglycopeptide fractions, four of which inhibited agglutination of Novikoff ascites cells by con A but not by WGA. DEAE-cellulose chromatography of the high molecular wt fraction resolved seven fractions, one of which could inhibit agglutination of ascites cells by WGA but not by con A.

4865 INSECT TRANSFER OF LABELED ERYTHROCYTES, WITH IMPLICATIONS FOR CIRCULATING TUMOR CELLS. (E.) Woke, P. A. (Dept. Biol., American U., Washington, D.C.) and N. Konwinski. *J Nat Cancer Inst* 48(1):219-222, 1972.

This study confirms that a bloodsucking insect, *Aedes aegypti*, could transfer circulating tumor cells of hamster reticulum cell sarcoma TM from tumor-bearing to tumor-free hamsters. Measurement of blood cell transfer, with chromium-51 as a tracer, a spectrometer system, and a well-type scintillation detector, are described. Radiochromium, identified in recipient hamsters, indicated that the fly *Stomoxys calcitrans* and the mosquito *A. aegypti* had transferred labeled erythrocytes by bite. A quantitative experiment indicated that *A. aegypti* transferred 0.00021-0.00066 μ l of blood to the recipients. These quantities normally contain approximately 1500-5000 red blood cells, 1.5-5.0 normal white blood cells, or, in leukemia, 10-132 tumor cells. Tumor developed from <10 tumor cells injected by needle. Insect transfer of blood from hamster to hamster implies that tumor cells from TM blood ingested from the peripheral circulation of a leukemic donor are potentially transferable to a tumor-free recipient. Such an occurrence provides a possibility for tumor to develop.

4866 ELECTROCONDUCTIVITY CHANGES DURING THE MITOTIC CYCLE IN EHRlich ASCITES TUMOUR CELLS. (E.) Malenkov, A. G. (USSR Acad. Sci., Moscow), V. L. Voeikov and Yu. A. Ovchinnikov. *Biochim Biophys Acta* 255:304-310, 1972.

Changes in electrical parameters of the plasma membrane during the mitotic cycle in Ehrlich ascites tumor cells were studied. Tumor cells (50×10^6) were inoculated i.p. in white mongrel mice and harvested seven to eight days later (500×10^6 to 600×10^6 cells/mouse). Five cell fractions were obtained after separating cells according to size by a velocity sedimentation technique in a linear gradient (5-45%) of bovine serum in Medium 199; fraction 1 contained cells with the highest speed of sedimentation and fraction 5 the slowest cells. DNA synthesis was followed using ³H thymidine tracer. Specific activity distribution patterns obtained for fractions 1-4 indicated that cell size depends on cell position in the mitotic cycle, i.e., fractions 1-2 and 3-4 were enriched with cells in the G₂, S and G₁ periods, resp. As measured by the bridge technique at 9 kHz, specific electroconductivity of the cells was high in the G₁ period, decreased by a factor of 2 to 2-5 in the S period and increased again in the G₂ period. Changes in cell electroconductivity are indicative of changes in the passive permeability of cells, periods of high permeability corresponding to membrane synthesis and initiation of cell division in autonomously dividing cells.

4867 THE PRESENCE OF "FETAL" THYMIDINE KINASE IN HUMAN TUMORS. (E.) Stafford, M. A. (Div. Med. Genetics, U. California, San Diego) and O. W. Jones. *Biochim Biophys Acta* 277(2):439-442, 1972.

Tissue extracts from surgical specimens of rhabdo-

myosarcoma, Wilm's tumor, bladder adenocarcinoma and a benign uterine fibroma were tested for the presence of a fetal type thymidine kinase. The fetal enzyme can be differentiated from the adult type by its inability to use CTP as a phosphate donor, its low activity at pH 4.5, the lack of inhibition by dCTP, and by its characteristic slow migration rate in polyacrylamide gel electrophoresis. On the basis of these criteria, the rhabdomyosarcoma, Wilm's tumor, and bladder adenocarcinoma all predominantly contained the fetal type enzyme, whereas the benign uterine fibroma, although containing some fetal type activity, primarily showed normal adult type activity. These results suggest that gene expression for human fetal thymidine kinase is repressed in post-natal tissues and in all probability is transmitted vertically as part of the host genome. This gene is apparently derepressed under certain conditions associated with carcinogenesis.

868 CHARACTERIZATION OF A FACTOR REQUIRED FOR THE DIFFERENTIATION OF MYELOID AND LYMPHOID CELLS IN VITRO. (E.) Watson, J. (Salk Inst. Biol. Studies, San Diego, Calif.) and J. Prichard. *J Immunol* 108(5):1209-1217, 1972.

Culture supernatants of leukemia virus-infected spleen cells of the JLS-V5 line were found to contain a factor which stimulated a primary immune response to sheep erythrocytes in immunologically unresponsive ALB/c or C57BL/6 mouse spleen cells prepared from nonimmunized mice and cultured in a medium deficient in fetal bovine serum. The same factor also stimulated the growth of colonies when mouse bone marrow cells were cultured in soft agar; factor-induced colonies contained cells which differentiated from immature granulocytes at early stages of growth into granulocytes and macrophages. The JLS-V5 culture supernatants were precipitated with ammonium sulfate, centrifuged and fractionated on a 90 x 3 cm Sephadex 100 column. Two main fractions were collected, and it was found that the ability to stimulate bone marrow and spleen cells was always associated with the same fraction. JLS-V5 factor was treated with a variety of enzymes and chemicals, including α -chymotrypsin, trypsin, pronase, collagenase, neuraminidase, ribonuclease, or deoxyribonuclease, urea, mercaptoethanol or dithiothreitol. The factor retained its ability to stimulate spleen and bone marrow cells through all treatments. Periodate treatment, however, destroyed the stimulatory activity of the JLS-V5 factor. Acrylamide gel electrophoresis indicated that the active component of the JLS-V5 factor had a molecular wt of 70,000 to 80,000.

869 CYCLIC 3', 5'-NUCLEOTIDE PHOSPHODIESTERASES OF NOVIKOFF RAT HEPATOMA, MOUSE L, AND HeLa CELLS GROWING IN SUSPENSION CULTURE. (E.) Schröder, (U. Minnesota Med. Sch., Minneapolis) and P. G. W. Bagemann. *Cancer Res* 32(5):1082-1087, 1972.

Cell fractions were prepared from Novikoff rat hepatoma cells (N1S1-67), mouse L cells (LB-67 and LG-67) and HeLa cells (HeLa-S3-67) by sonic oscillation or homogenization followed by centrifugation. The supernatant fractions were assayed for phosphodiesterase activity by measuring the production of ^3H -AMP from ^3H -cyclic 3',5'-AMP. At 0.4 mM cyclic 3',5'-AMP in the assay mixture, mouse L cells contained 20- to 40-fold more activity than N1S1-67 cells whose specific activity, in turn, was only five to 10% that of similar extracts from rat liver (six to seven μM phosphodiesterase/mg protein). Activity of mouse L cells (eight to 16 μM /mg) was three to four times that of mouse liver (three to four μM /mg). Twenty to 30% of the cAMP converted to AMP by N1S1-67 extracts was further converted to adenosine by 5'-nucleotidase. Mouse L cells showed no further degradation of cAMP; however, the conversion of cAMP (0.5-1.5 mM) to adenosine was almost quantitative (48% of total radioactivity) in HeLa cell extracts indicating a high level of 5'-nucleotidase in HeLa but not in L cells. Kinetic studies of enzyme activities of cell extracts at 0.25 μM to 1.0 mM cAMP indicated that there were two phosphodiesterase activities in each cell line; one with a low K_m (1.0 to 2.0 μM) and one with a high K_m (0.1 to 0.4 mM). The similarity of K_m 's for all four cell lines indicated similar phosphodiesterases in these lines despite their diverse origin. V_{\max} did differ between cell lines with that for the high K_m enzyme, being 30 times higher in L cell extracts (16 nmoles/min/mg protein) than in N1S1-67 extracts (0.55 nmoles/min/mg protein) and three to four times higher than in HeLa extracts (3.0 to 4.0 nmoles/min/mg protein). V_{\max} for the low K_m enzyme was similar (0.1 to 0.3 nmoles/min/mg protein) for all four cell lines. Over 90% of both enzyme activities was present in the "postnuclear" fraction of all four lines with most (60 to 70%) of the activity in the "cell sap". Both enzymes from all four cell lines were inhibited by theophylline with similar K_i 's (one to seven mM). However, the high K_m enzymes were competitively inhibited while the low K_m enzymes were inhibited in a noncompetitive manner. Both enzyme activities were independent of the cell growth cycle. Neither insulin (ten or 100 μM /ml) nor glucagon (5 μM) had any effect on either phosphodiesterase of N1S1-67 cells.

4870 POLYAMINE AND NUCLEIC ACID CONCENTRATIONS IN EHRlich ASCITES CARCINOMA CELLS AND LIVER OF TUMOR-BEARING MICE AT VARIOUS STAGES OF TUMOR GROWTH. (E.) Andersson G. (Inst. Zoophysiology, U. Lund; Sweden) and O. Heby. *J Nat Cancer Inst* 48(1):165-172, 1972.

The concentrations of putrescine, spermidine, spermine, DNA, and RNA in Ehrlich mouse ascites carcinoma cells were determined at various stages of tumor growth. The putrescine concentration was markedly elevated in the latter phases of rapid multiplication, but declined considerably with increasing tumor mass. The changes in the concentration of spermidine, spermine, and nucleic acids were similar to each other. There were concomitant maxima in the

polyamine-N/nucleic acid-P ratio and the number of prophase during tumor growth. The concentrations of polyamines and nucleic acids were also studied in the livers of tumor-bearing mice. The results clearly demonstrated that the transplanted ascites tumor greatly influenced the spermidine concentration in the liver. After a precipitous drop, it progressively increased to a value considerably higher than the initial value. However, the presence of the tumor did not markedly alter the DNA and RNA concentrations.

- 4871 FATE OF L-[3,5-³H] TYROSINE IN CELL-FREE EXTRACTS AND TISSUE CULTURES OF MELANOMA CELLS: A NEW ASSAY METHOD FOR TYROSINASE IN LIVING CELLS. (E.) Oikawa, A. (Natl. Cancer Ctr. Res. Inst., Tokyo, Japan), M. Nakayasu, M. Nohara and T. Tchen. *Arch Biochem* 148(2):548-557, 1972.

Cell-free extracts from cells derived from cultured melanoma (C₂M cells) were incubated with L-(3,5-³H) tyrosine (1 mM) in the presence of 0.1 mM dopa. The hydroxylation of tyrosine to dopa by tyrosinase was observed. C₂M extracts and labeled tyrosine produced tritiated water at a steady rate for 15 hr with conversion of 20% of added radioactivity. Melanin and dopa were also produced, but the compounds contained little radioactivity. Extracts of C₂W cells, derived from an amelanotic line of melanoma cells, produced neither tritiated water nor melanin. On culture of C₂M cells in the presence of L-(3,5-³H)tyrosine, the radioactive reaction products were water, melanin and protein. C₂W cells cultured in the presence of labeled tyrosine produced only tritiated protein, indicating that C₂W cells lacked tyrosinase. The ratio of the amount of tyrosine hydroxylated by tyrosinase (ΔTy) to water (W) was observed during incubation of C₂M cell-free extract and during cultivation of C₂M cells. The ratio ΔTy/W remained fairly constant for reactions with a wide range of reaction rates (1.4 for cell-free extracts, 1.1 for C₂M cells in culture). ΔTy/W was also constant for reactions using enzymes from different sources, including human melanoma.

- 4963 GROWTH OF A HUMAN LEUKEMIA CELL LINE ON PROTEIN-FREE MEDIUM. (E.) Buhl, S. N. (Oak Ridge Natl. Lab., Tenn.) and J. D. Regan. *Proc Soc Exp Biol Med* 140(4):1224-1227, 1972.
- 4964 CHARACTERISTICS OF A SERIALY TRANSPLANTED MOUSE MAMMARY TUMOR AND ITS TISSUE-CULTURE-ADAPTED DERIVATIVE. (E.) Rockwell, S. C. (Stanford U. Sch. Med., Calif.), R. F. Kallman and L. F. Fajardo. *J Nat Cancer Inst* 49(3):735-749, 1972.
- 4965 INCIDENCE AND CHARACTER OF THE SPONTANEOUS PITUITARY TUMORS IN STRAIN CR AND W/Fu MALE RATS. (E.) Ito, A. (Inst. Cancer Res. Columbia U., New York, N.Y.), P. Moy, H. Kaunitz, K. Kortwright, S. Clarke, J. Furth and J. Meites. *J Nat Cancer Inst* 49(3):701-711, 1972.
- 4966 ALVEOLAR SOFT-PART SARCOMA. A CASE REPORT. (E.) Reynolds, S. A. (Havre, Mont.) and W. K. Solonar. *Rocky Mt Med J* 69(5):60-63, 1972.
- 4967 COMPLEMENTARITY BETWEEN MESSENGER RNA AND NUCLEAR RNA FROM HeLa CELLS. (E.) Stampfer, M. (Dept. Biol., Mass. Inst. Tech., Cambridge), M. Rosbash, A. S. Huang and D. Baltimore. *Biochem Biophys Res Commun* 49(1):217-229, 1972.
- 4968 BINDING OF RADIOACTIVELY LABELED CONCANAVALIN A AND RICINUS COMMUNIS AGGLUTININ TO RAT LIVER- AND RAT ASCITES HEPATOMA-NUCLEI. (E.) Kaneko, I. (U. Tokyo, Japan), H. Satoh and T. Ukita. *Biochem Biophys Res Commun* 48(5):1504-1510, 1972.
- 4969 DNA SYNTHESIS IN CHRONIC MYELOGENOUS LEUKEMIA CELLS: COMPARISON OF RESULTS IN

- CELLS CONTAINING FOLATE BINDING FACTOR TO REPLICATING
CELLS WITHOUT BINDER. (E.) daCosta, M. (New York
d. Coll., N.Y.), S. P. Rothenberg and B. Kamen.
Food 39(5):621-627, 1972.
- 470 ULTRASTRUCTURAL STUDIES IN ACUTE PROMYELO-
CYTIC LEUKEMIA. (E.) Tan, H. K. (Natl. Inst.
th., Bethesda, Md.), B. Wages and H. R. Gralnick.
Food 39(5):628-636, 1972.
- 471 ADRENAL FUNCTION IN CANCER: RELATION TO
THE EVOLUTION. (E.) Saez, S. (Med. Biol.
ervice, Lyon, France). *Eur J Cancer* 7(5):381-387,
71.
- 472 COMPARATIVE ULTRASTRUCTURAL STUDIES OF
CELLS FROM TUMORIGENIC AND NON-TUMORIGENIC
CULTURES DERIVED FROM THE 6C3HED MOUSE ASCITES TUMOR.
(E.) Banks, W. J. (Coll. Med., U. Saskatchewan,
nada), M. K. Bhatnagar and J. F. Morgan. *Eur J*
Cancer 7(5):433-439, 1971.
- 473 ELECTRON MICROSCOPIC STUDIES ON NEPHRO-
BLASTOMA (WILM'S TUMOR) IN MAN, IN PARTICULAR,
THE VIRUS-LIKE PARTICLES DETECTED WITHIN THE NU-
CLEUS. (E.) Noda, S. (Kurume U. Sch. Med., Japan).
Kurume Med J 19(2):61-79, 1972.
- 474 SHAPE AND MOTILITY OF CULTURED HUMAN LYMPHO-
BLASTOID CELLS. (E.) Miyoshi, I. (Okayama
U. Med. Sch., Japan), T. Tsubota, H. Hasegawa and K.
Braki. *Gann* 63(3):361-363, 1972.
- 475 RELATION BETWEEN REPLICATING DNA AND NUCLEAR
MEMBRANE IN L5178Y LEUKEMIA CELLS. (E.)
jiwara, Y. (Kobe U. Sch. Med., Japan), T. Kondo,
Kawamoto and C. Uchiyama. *Gann* 63(3):291-298, 1972.
- 476 COMPARATIVE EFFECTS OF MARE, STALLION,
GELDING HORSE, AND FETAL BOVINE SERA ON NEO-
PLASTIC TRANSFORMATION *IN VITRO*. (E.) Evans, V. J.
at. Cancer Inst., Bethesda, Md.), F. M. Price,
K. Sanford, H. A. Kerr and S. L. Handleman. *J Nat*
Cancer Inst 49(2):505-511, 1972.
- 477 EVIDENCE FOR AN INHIBITING INFLUENCE OF
FETAL BOVINE SERUM ON "SPONTANEOUS" NEO-
PLASTIC TRANSFORMATION *IN VITRO*. (E.) Sanford, K. K.
at. Cancer Inst., Bethesda, Md.), J. L. Jackson,
Parshad and R. R. Gantt. *J Nat Cancer Inst* 49
(2):513-518, 1972.
- 478 MESOTELIOMA PERITONEAL. (Sp.) Rubies Prat,
J. (Sanitary City, Social Security, Barcelona,
ain), M. Soler Obradors, J. Casalots, C. Mas Martinez
and R. Bacardi Noguera. *Med Clin* 58(3):217-219, 1972.
- 49 PAGET'S DISEASE OF THE MALE BREAST. (E.)
Coley, G. M. (Hartford Hosp., Conn.) and
P. G. Kuehn. *Am J Surg* 123(4):444-450, 1972.
- 4980 IDENTIFICATION OF ISOCHROMOSOME 17 IN
MYELOID LEUKAEMIA. (E.) Lobb, D. S.
(Royal Marsden Hosp., London, England), B. R. Reeves
and S. D. Lawler. *Lancet* (7755):849-850, 1972.
- 4981 MALIGNANT DISEASE OF THE VULVA. (E.)
Kelly, J. (London Hosp., England). *J Obstet*
Gynecol Br Commonw 79(3):265-272, 1972.
- 4982 SIMULTANEOUS BILATERAL PRIMARY BREAST CAR-
CINOMA IN THE MALE. (E.) Wolloch, Y.
(Beilinson Hosp., Petah Tikvah, Israel), M. Zer,
M. Dintsman and I. Kozenitzky. *Isr J Med Sci* 8
(2):158-162, 1972.
- 4983 RELEASE OF FIBRINOLYTIC ACTIVATORS FROM
HUMAN TUMOURS CULTURED *IN VITRO*. (E.)
Björlin, G. (Gen. Hosp., Malmö, Sweden), M. Pandolfi
and B. Astedt. *Experientia* 28(7):833-834, 1972.
- 4984 CONTROL OF CARCINOGENESIS: A POSSIBLE ROLE
FOR THE ACTIVATED MACROPHAGE. (E.)
Hibbs, J. B., Jr. (Palo Alto Med. Res. Fdn., Calif.),
L. H. Lambert, Jr. and J. S. Remington. *Science* 177
(4053):998-1000, 1972.
- 4985 MYELIN FIGURES ASSOCIATED WITH THE CYTO-
PLASMIC MEMBRANES IN HUMAN MEDULLOBLASTOMA.
(E.) Tani, E. (Kyoto U. Med. Sch., Japan), N. Higashi.
Acta Neuropathol 21:128-139, 1972.
- 4986 HORMONAL EFFECT ON TYROSINE AMINOTRANSFERASE
ACTIVITIES IN YOSHIDA SARCOMA AND ITS VARIANT
LINES. (E.) Watanabe, M. (Res. Inst. Tuberculosis,
Leprosy, Cancer, Tohoku U., Sendai, Japan). *Gann*
63(4):397-407, 1972.
- 4987 MICROSCOPIC LUNG METASTASIS FROM THYROID
ADENO-CARCINOMA DISCOVERED AT AUTOPSY. (E.)
Iwanaga, T. (Ctr. Adult Dis., Osaka, Japan), H. Koyama,
Y. Takahashi, G. Kosaki and A. Wada. *Gann* 63(4):437-
443, 1972.
- 4988 POST-MORTEM FINDINGS IN UGANDANS WITH
HODGKIN'S DISEASE. (E.) Dhru, R. (Dept.
Path., Makerere U., Kampala, Uganda) and A. C. Templeton.
Br J Cancer 26(4):331-334, 1972.
- 4989 IMBALANCE IN ORNITHINE METABOLISM IN
HEPATOMAS OF DIFFERENT GROWTH RATES AS
EXPRESSED IN BEHAVIOR OF L-ORNITHINE CARBAMYL TRANS-
FERASE ACTIVITY. (E.) Weber, G. (Indiana U. Sch.
Med., Indianapolis), S. F. Queener and H. P. Morris.
Cancer Res 32:1933-1940, 1972.

- 4990 MALIGNANT HISTIOCYTOSIS WITH CUTANEOUS INVOLVEMENT AND EOSINOPHILIA. (E.) Liao, K. T. (Washington U. Sch. Med., St. Louis, Mo.), J. Rosai and K. Daneshbod. *Am J Clin Pathol* 57(4): 438-448, 1972.
- 4991 SYNTHESIS AND TURNOVER OF RNA IN THE 30-S NUCLEAR RIBONUCLEOPROTEIN COMPLEXES OF MOUSE ASCITES CELLS. (E.) Martin, T. E. (Dept. Biochem., Genetics, U. Washington, Seattle) and B. J. McCarthy. *Biochim Biophys Acta* 277(2):354-367, 1972.
- 4992 SERUM-MEDIATED STIMULATION OF PROTEIN SYNTHESIS IN EHRlich ASCITES TUMOR CELLS. (E.) Kaminskas, E. (Harvard Med. Sch., Boston, Mass.) *J Biol Chem* 247(17):5470-5476, 1972.
- 4993 REPRESSION AND DEREPRESSION OF PURINE BIOSYNTHESIS IN MAMMALIAN HEPATOMA CELLS IN CULTURE. (E.) Martin, D. W., Jr. (Sch. Med., U. California, San Francisco) and N. T. Owen. *J Biol Chem* 247(17):5477-5485, 1972.
- 4994 PHOSPHORYLATION OF RIBOSOMAL PROTEINS IN SARCOMA 180 TUMOR CELLS. (E.) Bitte, L. (U. Oregon Med. Sch., Portland) and D. Kabat. *J Biol Chem* 247(17):5345-5350, 1972.
- 4995 PHEOCHROMOCYTOMA - EXPERIENCE WITH 17 PATIENTS. (E.) Atuk, N. O. (U. Virginia Hosp., Charlottesville). *Va Med Mon* 99(5):518-524, 1972.
- 4996 INCORPORATION OF URIDINE-³H AND SODIUM ACETATE-¹⁴C IN LYMPHOCYTES DERIVED FROM NORMAL AND LEUKEMIC INDIVIDUALS. (E.) Mukherjee, A. B. (St. U. New York, Sch. Med., Buffalo), R. G. Waite, M. N. Cohen and R. Bernstein. *Cancer Res* 32:1833-1836, 1972.
- 4997 TRANSLATION OF MESSENGER RNA FOR HISTONES FROM HeLa CELLS BY A CELL-FREE EXTRACT FROM MOUSE ASCITES TUMOR. (E.) Jacobs-Lorena, M. (Dept. Biol., Massachusetts Inst. Tech., Cambridge), C. Baglioni and T. W. Borun. *Proc Nat Acad Sci USA* 69(8):2095-2099, 1972.
- 4998 REGULATION OF TYROSINE HYDROXYLASE ACTIVITY IN CULTURED MOUSE NEUROBLASTOMA CELLS: ELEVATION INDUCED BY ANALOGS OF ADENOSINE 3':5'-CYCLIC MONOPHOSPHATE. (E.) Waymire, J. C. (U. Colorado, Sch. Med., Denver), N. Wiener and K. N. Prasad. *Proc Nat Acad Sci USA* 69(8):2241-2245, 1972.
- 4999 STATISTICAL ANALYSIS OF SURVIVAL EXPERIMENTS. (E.) Hoel, D. G. (Natl. Inst. Environmental Hlth. Sci., Research Triangle Park, N.C.) and H. E. Walburg, Jr. *J Nat Cancer Inst* 49(2):361-372, 1972.
- 5000 RESPONSE OF HEPATIC ENZYME ACTIVITIES TO CASTRATION AND SARCOMA 37 GROWTH IN DIFFERENT MOUSE GENOTYPES. (E.) Wolff, G. L. (Inst. Cancer Res., Philadelphia, Pa.) and H. C. Pitot. *J Nat Cancer Inst* 49(2):405-413, 1972.
